done at home. There is also the Accommotrac which you have mentioned which is used as far as I know mostly or only? by behavioral optometrists. I would reccommend any of those three approaches for your daughter, and the younger the better, since it is easier to change the system in kids than adults. There is an OD who studied with and was treated by Dr Amiel Francke of Washington, DC a real pioneer in myopia reduction. She totally got rid of her myopia and threw away her glasses. She was so stoked that she went to optometry school (she was a teacher at the time) and now teaches and practices these methods at Harvard University and New England Optometry College. She wrote up her own case study in the Journal of the American Optometric Association in either 1995 or 1996. A Medline search should turn it up for you. If you need the reference, let me know and I will try to find it.

- 

I just read a fascinating book called "Fasting and Eating for Health" by Joel Fuhrman, M.D. In this book the doctor explains how many chronic diseases and medical conditions have been resolved by combining a low-fat pure vegetarian diet with a fast which allows the body to repair damaged areas.

In some of the case studies he mentioned that people have had improved vision and even a deaf person who surprisingly regained his hearing during the fast.

While I am in good health overall, I am pretty much obsessed with improving my myopia (now at -4.5 diopters in each eye) and am thinking about trying a fast out of curiosity .. any thoughts or ideas ?

I agree that VT people need to be more cross disciplinary and that many are not. I am hoping to bring in my fascination with psychology and body work to VT.

You are right. I have noticed that one reason (some!) people listen to me when I talk about VT is because I have been through it as a patient, a therapist, a parent, and now a student. Others who know it mostly from books seem to be less credible to people who want to learn about it. I think it is the subjective, emotional, I care about this stuff, attitude

that makes all the difference.

I suspect it may well be a personal thing. I have to admit that I didn't manage to do anything other than give myself bad and long-lasting eyestrain with my own attempts at the Bates method.

Now, a couple of years later I'm ready to try again, but I feel discouraged and definitely in need of my behavioural optometrist to give me another chance.

Here is the actual reference you mentioned:

Seeing Space - Undergoing Brain Re-Programming To Reduce Myopia  
by Antonia Orfield O.D.

Significant quotes from paper published in the Journal Of Behavioural  
Optometry, Vol 5.1994.Page123-131.

Functional Myopia is not just an imbedded (accommodative) spasm and it is  
not just an enlargement of eyeballs. It is a reflection of the shrinking of  
the brain's space world by closure of the periphery, first by stress, then  
by errors in spatial judgement induced by minus lenses.

Children's space world has shrunk down to to primarily central vision, so  
that they cannot judge distances. The (minus) lenses induce such warped  
vision in the periphery that their brains have to screen it out.....Lenses  
deepen their discolation in space.

Enjoy,  
Robert-Michael Kaplan.

Go for it! It is supposed to 'spring clean' your body and mobilise all sorts of toxins that get stored in odd places. Who's to say that the eyes aren't affected along with other parts that are more widely talked about?

If so, I guess they may even be a little worse to begin with (in the headache phase of toxin mobilisation, before the elimination phase).

I trust you'll let us know either way....

Mei-Tien;

Yes, there is literature out there to support that. I only know of one article in the optometric literature and haven't found any in the chiropractic literature. There is some in the osteopathic literature- a DO ophthalmologist in Australia. The optometric article is about a completely blind patient who had his eyesight restored by chiropractic adjustments to the cervicals. I have these references somewhere and if you want can get them out to you.

I am probably the last on the list to read it, but I just started Aldous Huxley's "The Art of Seeing." In the part where he describes palming, he mentions the at first, Bates had people "try" to see blackness. Later on, he changed his position ( because folks were straining ) and suggested pleasant visualizations (with movement) or recollections from childhood. I am really enjoying this book. I find my head nodding up and down as I read. This man was born in the late 1800's and died in 1963. I think the book was written in 1957.

So, has everyone else read it? I hate to be the last!

Herb,

Since you mentioned chiropractor, I wonder if anyone has any positive experiences in correcting c2 c1 ( neck bones relating to eye ) for improving eyesight??

>Hello fellow Vision Enthusiats.

>I am very curious about the results that people are experiencing using  
>Vision Freedom (sold by Brian Severson). I asked the same question a few  
>weeks ago but my name had been mistakenly removed from the list so I  
>never got an answer.....Any replies are welcome.

I tried Vision Freedom before I ever knew about VT and this mailing list. It didn't work for me, and I will return the kit for a refund, but that's not to say that it won't work for you. Mr. Severson's concept is based on the "plus-lens therapy" which you can do by yourself for just a few dollars (please refer to earlier posts). My greatest disappointment with Vision Freedom is that when I spoke to Mr. Severson to inquire about the types of lenses in the kit, he stated that he was "unable" to describe them. I'll let you be the judge of his ethics for that instance.

It all depends upon how willing you are to experiment and what you personally and truly believe will work for you. In two years I went from - 4.50 to - 3.00 diopters by reducing what I considered to be the negative stimuli to my eyes (long story). As a result, my optometrist is very open-minded to my input and is working with me to further reduce my optical deficiencies.

In conclusion, no one can say that Vision Freedom will/won't work for you, as the theory does have it's merits, but I do think that you can duplicate the process at a more realistic price. Please let me know of your decision.

Good Luck,

Pete Alexion

I have gone veggie and have noticed a calmer digestive track and i believe a simplified flow of moods. None of my annoying stray un-sourceable bad moods have occured since i started 4 months ago, and my theory is that the digestion of meat was causing them. You are what you eat (and absorb) and i have been taking that to its logical limit, wanting to avoid anything not fresh or sprayed or processed at all. It's satisfying physically and psychically.

Fasts are used by many to 'purge' and break out of ruts. If you feel like kicking yourself in the butt, go for it! I dont have any personal experience with fasting though. I do skip eating to feel actual hunger from time to time.

The prescriptions are -5 -5 from one place, and she was rechecked a few weeks later at a different place and got -4.5 -3.75 with .5 astigmatism. Her dark pupils seem to be a little closer than before when she looks straight, I wonder if this has anything to do with her wearing her old glasses occasionally( -2.5 -2, got it about two years ago).

I tried to get her doing sunning and palming...

>

It's funny you should mention it, I was just thinking about going out  
and buying it.. I havent read it yet! I was just re-reading the sections  
on palming in the original Bates book, and another book by a pupil of  
Bates: "Help yourself to better sight" by Margaret Darst Corbett.

In the original Bates book, Bates spends a lot of time talking about  
visualizing the blackness.. the second book has no mention of the  
blackness.. Also, in the second book are many quotes from Aldous  
Huxley's "The Art of Seeing."

Bates described a man with multiple vision problems.. cataracts, myopia  
and presbyopia who palmed for 20 hours straight and recovered his  
vision.. palming can be one of the most effective VT methods in

some subjects.

And what were the results? Also, what is your daughter now actually wearing?

I remember about a year ago (in personal communication) you said she had a clear flash while practicing with the Snellen chart.

If you're like most people, school is about to begin. This is probably the worst menace to the eyes. Children are forced to sit still with nothing pleasant to look at. Many tend to stare at their fingers or desk. They are prescribed lenses so they can see the chalkboard, but how much time is spent looking at the chalkboard?

Your daughter needs DISTANT VISION PRACTICE. As I understand, she is still quite young. If adults can reduce their prescriptions by a diopter,

surely your daughter can achieve at least that much, by practicing looking at ever more distant objects WITHOUT GLASSES.

It sounds now as if she is going cross eyed.

Do not be satisfied with the halfway solution of bifocals that one doctor prescribed. These are a passive non-solution. They reduce the amount of exercise the eyes can get, and for this reason I feel they may in some ways be worse than traditional glasses. They may reduce near demand relative to traditional glasses but they can NEVER increase distant stimulus, which is what your daughter needs in order to improve her vision.

I have some questions to help you decide what you can do, what prescription might help, and what prescription would hurt.

1. How old is your daughter?
2. How far can she see absolutely clearly without glasses? That is, at what distance do things start to get a little blurry?
3. Is she comfortable without glasses?
4. At what times of day can she see well, at what times of day does she see poorly?
5. How much time does she spend outdoors each day?
6. What is her attitude towards vision improvement (very important)?
7. Did your optometrist ask these questions?

That is an interesting concept. BTW, I just got back from barns and noble with your book: Seeing without glasses. I can't wait to read it, does it talk about the same types of concept as in the paper?

Mary Marlowe confessed to reading Huxley's book at such a late date. Me too. I'll ante up on that one. I am taking my time reading it and it does appear to be a primer in self-actualization. I only recently finished his Doors of Perception. The man was cool before the word cool was invented.

Herb,

Thanks so much for your detailed relply. I am in the process of studying  
all these methods which can help. I would love to read the reference  
you mentioned at the end of your mail. I have never done medline search  
before. Where to do on the WWW and which key words to use??

Thanks  
Mei-Tien

> palming can be one of the most effective VT methods in some subjects.

Everybody goes on about palming but I find it very difficult to ever manage it properly. It's so uncomfortable unless you have something to lean on and people would think I was ill if I did that at work. Usually I try to do one eye while I'm on the phone at work (or both if I am using a headset), but then I'm thinking and talking about work instead of relaxing.

Is this next to useless and do you really need to do both eyes, relax your thoughts and keep your eyes still for it to work? I have been assuming that resting one at a time (even if it is moving physically, it won't be focussing) is better than nothing.

Caroline

Thats why I said "some" subjects.. I have a hard time with it as well, and I am trying to get better at it. I have seen some success with it before, but can't reproduce it as regularly as I like. I tend to get tired after 5 minutes or so. I think I am trying too hard when I really should be not trying.. just relaxing!

```

Palming with one eye might might work for some, but I think it would stress me out.  
Whatever feels like it works for you. Everyone is different.  
Relaxing and trying to think of something pleasant or some joyful memory  
and not worrying what your eyes are doing is probably the best.

BTW: on your response to fasting:

> Go for it! It is supposed to 'spring clean' your body and mobilise all  
> sorts of toxins that get stored in odd places. Who's to say that the eyes  
> aren't affected along with other parts that are more widely talked about?

> headache phase of toxin mobilisation, before the elimination phase).  
>  
> I trust you'll let us know either way....  
>  
> Caroline

I may try a short fast .. 3 days or so... I should probably get  
a doctor to help me if I do it longer. A longer fast would probably  
require time off from work, a Doctor to monitor me, etc.

I'll bet the key is circulation.. since fasting improves the  
circulation of the blood, the eyes get the benefit as well as  
the rest of the body.

Of course I'll let the list know if I do it and what the results are...

Re Aldous Huxley: one of the exercises that worked for me really great for a few months came from this book. Huxley mentions a Spanish VT doctor who invented it. You close your eyes and visualize your hand loosely holding a flexible ring between your thumb and forefinger, in horizontal position; mentally move your gaze along its circumference, then apply slight pressure so that it goes from round to elliptical, follow the elliptical shape with your mental gaze, release the pressure, follow the round shape; then turn the ring vertically and do the same. I used it many times, visualizing rings of varying flexibility and transparency, then a ball, pitch black or made of light, made of "energy," of "antimatter," what-not. You get into it and eventually start feeling pulsations or pulling sensations in/around your eyes (Huxley talks of physical sensations of some "rearrangements" in the eyes). It must be efficient due to the fact that areas in the brain responsible for hand and eye coordination are tightly interconnected. I've read about studies that showed that visualization dramatically increases blood flow to the visual cortex (up to six times) and stimulates new dendrite growth in neurons and the appearance of new connections.

Re fasting: no, I didn't do it on purpose, but when changes in my vision became quite dramatic I noticed a number of coincident changes in overall physiology (for instance, a slight permanent drop in body temperature) and at some point lost my appetite completely. I lost some weight for the first time in 25 years (not happy about it at all -- I didn't really have much to spare) and am back to my pre-myopic indifference for food (I do hope temporarily!). A question for Herb Black and Robert-Michael Kaplan: have you ever observed anything of the kind in your VT patients?

Re survey: I'm deeply grateful to all who have responded so far. Something's cooking, I'm quite a bit intrigued by the emerging picture! This is a request to those who haven't responded yet: please do. The category I'm most interested in, the high myopes, is so far the least

well-represented -- please people, don't hide in your "inner space," it's not good for your eyes :-). I paste the questionnaire below once again, in case someone has misplaced it.

\*\*\*\*\*

I will share the statistical results with everybody and GUARANTEE ANONYMITY to all respondents. I expect either some eye-opening correlations everyone will be able to see, or a refutation of my present theory (partial or total). I am open to either outcome (I went through the process of defying my own next-to-last hypothesis a number of times and I don't mind being proved wrong -- a negative result is a result none the less.) I'll share the theory in its entirety, and in case it's as significant as I now think it is, the repercussions for our present "let's reclaim our vision" quest will be direct.

Here goes:

I. Please respond in figures to questions in this section.

1. At what age was your vision problem first diagnosed?
2. How strong was your first prescription? What was your unaided acuity?
3. How high was your refraction error at its highest? At what age?
4. How bad is it now? How old are you?
5. For how many hours a day did you wear your glasses/contacts at various ages?
6. Did you wear full-strength glasses for near-point work (reading, etc.)?
7. Average daily amount of near-point work at different ages?

II. Please ask your mother for details if you don't know the answer to any of the questions in this section.

1. Were you born at full term or premature? If premature, specify age in addition to weight.
2. Complications at birth (if any): a) normal natural birth; b) Caesarean; c) cord strangulation; d) suffocation on fluids; e) a twin; f) other. Please include details (wasn't breathing/had to be revived, bluish or purple skin color, loud/weak crying, etc.)
3. Was your mother medicated with tranquilizers or painkillers at any time while in labor?
4. The duration of labor?
5. Ask your mother if she remembers any details of the environment of the delivery room: cold/hot, noisy and hectic/quiet, etc.. Give details if you can.
6. The lighting of the delivery room: bright/dim, incandescent/fluorescent, few/many reflections from bright-lit objects, etc.
7. Were you separated from your mother immediately after birth? If yes, for how long?

III. Be specific or poetic in this section, whichever seems appropriate.

1. Please describe the circumstances around the time when you first started noticing difficulties with your vision.
2. Can you recall any specific experiences that made you aware of a change in vision for the first time?

I look forward to your answers!

Elena

Could anyone please let me know if there are any Opticians in the U.K. who practice these alternative techniques of eyecare?

I've tried asking a couple but the Ophthalmic opticians say that this stuff is not part of their training...

So does anyone know of anyone in the U.K.???

Thanks very much, as this will save me explaining the basics to everyone i ask....

I have tried it on my 10 year old daughter for a couple of times. It was some sort of electrical pulse pressed on the acupuncture points on her face( I forgot the details). I was told if this method is useful it will show the effects rather quickly, but in my daughter's case, it did not help.

But, now I do ask her to use her hands to press the acupuncture points around her eyes sometimes.

Pete,

I also got Vision Freedom about two weeks ago. I seemed to get a little effect in the first two days( although it might also be that my eyes rested for a whole night when I checked it in the morning, it seems to be two line better than the previous night ). Now that I could not get any progress.

I started to read Kaplan's Seeing without Glasses. Found the concept of vision fitness glasses appealing. 20/40 glasses give you a constant "cross the line" effect....? Have you tried it? I would love to hear your long story about getting your vision to -3.

Dear Seers,

I have been having some great results lately, perfect to near perfect vision for periods up to hours when i can put the right conditions together. At these times, many realizations occur and i think they are mostly specific to myself but one thing i noticed yesterday i thought may be of general interest.

It has to do with with peripheral vision. Without a doubt the widening of this is essential. The exercise 'swinging' and watching the apparant motion of all objects is a good one to develop this. This can become an 'exercise' which one can do at all times whether swinging or not and is really not so much an exercise but an 'attitude' or 'state' it seems to me, where the mind does not fixate but rather is open to every visual impression.

I thought about the act of hearing. I have perfect hearing and i noticed that in the realm of sounds, i don't 'expect' or 'try' to hear anything. It's a continuum of sounds and i can hear them bouncing in from all corners and i dont really 'care' that much about the sounds, they are what they are and i just hear them.

I related this to my vision. when up close, i can see everything fine and there is no effort to see anything, it is all just right there. But when i look distant i start to have difficulty. I noticed that when i think of the visual field as a continuum of light similar to a continuum of sound, the light streaming into my eyes rather than me trying to see THINGS, the desired peripheral vision effect was enhanced. I noticed that when i focused on something in the distance, i could percieve much more detail and the depth perception was enhanced.

I hope i've expressed the subtlety well. It is a powerful new 'trick' for me.

dear Seers,

Motivation, for VT or anything, is the crux of causing willed changes.

It is possible to make a determination to start practicing a certain behavior but everyone has experienced the subsequent loss of desire to keep up the regimen, and the eventual dropping of it or the reduction to half-hearted effort.

The common response is that one is not disciplined enough, while this is true, it kind of begs the question--changing determination into discipline is just another undefined word.

Discipline or determination depends upon the source. When the source of the plan is external to oneself the plan will fail. External sources include 'well reasoned essays', pressure from friends, parents, employers, spouses, 'society'. Conversely, when the source of the motivation is from a personal desire--free from all such foreign concerns, when the notion is simply something that one DESIRES, the motivation is automatic, the completion is assured. In short, lack of motivation is NOT a weakness, it is a misnomer. Success in any change depends upon the sorting out of one's PERSONAL priorities. All desire is valid and is a key to the process of Understanding. Discipline is not necessarily an aggressive imposition but rather an intelligent and honest \*organizing\*

i have experienced both situations and believe that no foreign motivation will succeed.

Force fed and trained animals show signs of weakness and will fail without constant supervision. Highly trained soldiers show signs of serious stress and breakdown despite their accomplishments. The practice of imposing

Change upon Nature is frequently irrespective of the full force of the situation. Change must be accomplished on the timetable which accomodates the whole scenario. Everyone's eye condition is unique and the steps necessary to solve the problem are unique. Each stress must be dealt with in the time necessary and done properly. the insistance on a timetable is an \*additional\* stress and will only delay completion.

no hurry!

Hello Marco

In a message dated 96-08-08 07:15:41 EDT, you write:

<<

Thank you for responding. I still have a few questions about VF if you do not mind.

>

> I tried Vision Freedom before I ever knew about VT and this mailing list.

It

> didn't work for me, and I will return the kit for a refund, but that's not to

> say that it won't work for you. Mr. Severson's concept is based on the

>Well - if he does refund your money with no questions asked, then I

>would feel confident about getting the kit.....

I'm sure that he'll have a "few questions", but remember that you're the customer and that he does offer a 100% refund. He states in his literature that he will work with anybody to achieve their goals at his expense (i.e., the telephone calls), but judging from the quality of his literature, I personally don't believe that he is any more knowledgeable about the subject matter than you or I are.

> "plus-lens therapy" which you can do by yourself for just a few dollars

> (please refer to earlier posts). My greatest disappointment with Vision

> Freedom is that when I spoke to Mr. Severson to inquire about the types of

> lenses in the kit, he stated that he was "unable" to describe them. I'll

let

> you be the judge of his ethics for that instance.

> I presumed it was + lenses.....does it also involve exercises?

Yes. You hold printed material until it is barely out of focus in order to encourage an "autofocus" which is supposed to make the ciliary (implied) and other ocular muscles stronger. Each subsequent autofocus allegedly will last longer until you've reached your goals.

>What is the daily ritual of the Vision Freedom person?

A maximum of two hours per day.

>Is the manual any help?

Just slightly.

>Does he for example suggest you

>start with low + and move to stronger + as excersises?

Yes, but only as your vision improves. Of course, transition lenses would be useful unless you would prefer to wear a plus lens over your minus lens.

>Any description or help is appreciated!!!

The literature provided is mostly hype and the pertinent information can be summed up in approx. one page...but doesn't.

>Let me tell you about my position. I do not mind paying for

>VF, even if it is a set of semi cheap + glasses. I believe that

>people have the right to profit for an idea that works....I just

>dont want to be taken for a ride. If his offer works - I'll pay.

>>

I agree on both counts. This is just my opinion, and I may be wrong, but considering the time frame that he's been working with this concept, and his age, and the fact that plus-lens therapy has been around for a century, I don't believe that he has pioneered the concept...just marketed it (God Bless America). To reiterate my previous point; look at the earlier posts and spend just a few dollars. Besides, the quality of the lenses that are included in Mr. Severson's kit is quite poor and you might find them somewhat irritating as I have found the lenses to be.

I intend to read through the VF literature one more time to see if there is a point that I missed, before returning the kit. If I encounter any obstacles, I will definitely post them. Should you decide to purchase the kit, please let me know of your results. Perhaps there is something that I overlooked.

I suggest that you speak directly to him on his toll-free line and decide for yourself if you're buying a product from a knowledgeable and reputable individual.

Good Luck,

Pete Alexion

I'm sorry to rant about such a small improvement, but I was excited because I've never shown any progress before (unless you count eyestrain!)....

I went to my behavioural optometrist last night (after 7 weeks in all) and he said that my left eye had improved from -0.5 to -0.25 (and that my right eye was nearly down from -1.0 to -0.75, but not quite).

The reason I'm excited, apart from it being my first improvement, is that I haven't seen anyone posting anything about minor myopic cases improving before. I'm sure there must have been plenty, but in recent months all the stories I've seen have been people with a higher degree of myopia. That and the recent question about progress perhaps being logarithmic, were making me pessimistic (a bad sign to start with). I was even wondering if you could only improve from where you were to a level of around -1.0D, which is the starting point for my worse eye!

NB In case you're wondering what I'm complaining about since my eyesight isn't too bad, I do agree that if either the high or the low myopes had to find it harder to improve than the other group, that it would only be fair for it to be the lower ones!

Caroline

For me, a perfectly-timed posting. I had been going to ask the  
list for any suggestions for improving peripheral vision  
(important for a cyclist looking over his shoulder, and  
probably useful for all road users).

Thank you.

Anyone seen this before? Any takers willing to try and report back?  
Caroline.

-----

"This exercise is a real simple, yet very powerful one that will lets you make your own eyesight four times as good. You will be able to improve seeing things from far away just as sharp and clear and big as if it were only a couple of feet away. Now I know this sounds really un-believable to you right now, but as you keep on thinking and as you keep on doing the exercise you will actually find your eyesight improved a little bit each and every time you do. So, let's go to it and begin:

Just a little while ago, I was talking to some people about what could be possible doing NLP and hypnosis. I then went to a great seminar with Paul McKenna and Michael Breen. That seminar was held in London and was presenting the Structure of Hypnosis to everyone attending it. We were doing all kinds of the so called deep trance phenomenons as Michael suddenly mentioned, that shamans actually go inside animals and asopt all of their behavior. That really struck me like a lighting bowl. Should it really be possible to do something like that ? Will it be possible to take those perfectonized skills and just take inside and act with them in day to day life ?

These two questions kept going around inside my mind now, as I began to develop the following exercise. In this exercise you will adopt the

perfect eyesight of an eagle, who is -as research has shown- able to see very small point from a huge distance. One scientist once told me, that "if he was able to read, he could read a newspaper from almost a mile away !"

Now, having thought of that, I then sat down and went into a real "deep" self hypnosis trance where I now remember all pictures and scenes where I have ever seen an eagle flying, sitting, hunting or else. I make the images turning into a slow moving movie and make them real (!) big, colorful, contrastful, surrounding as I'm turning up the volume and tone of only the sound I hear the eagle making, because that's what I am focusing on. Then I made my almost real eagle land at the ground and slowly turn toward me, because it is important to actually see his face looking how he does. As the eagle slowly walks towards me the whole scene turn around so that the eagle is walking away from me as I step forward inside him as he continues to grow as big as I am. Then I slip into his skin of feathers and experience every single move he is making. I breath the same rate and way he is and then I turn me head the exact same way he does as he slowly turns over control to me.

Have you ever noticed how an eagle keeps his head in one position like a still-shot-camera even when the rest of the body is moving a little bit ? Now, thinking of that and adopting this to my behavior too I suddenly realize how I can change the focus of my eye as if I was looking through a binocular, zooming in to what it is I want to see. My peripheral vision actually gets totally unfocused and I only see the center in a most bright, clear and sharp way. I hold my eyeballs looking straight forward out of my head and if I want to look at something else, I'm moving my whole head, blink, and open the eyes looking at the next point of interest.

After having done this for a while, I thank my eagle for letting me experience this phenomenon of nature, this magic found inside him as he takes over control and flies away. But there is a small feather slowly going down into my hand, reminding me of my own capabilities and that I now have learned, how an eagle can see myself looking sharply into the future.

I noticed, that doing this exercise a couple of time a day improved my eyesight a whole lot. Thus convinced I am now moving on to the next skill, but that is yet another story I will tell you then . . .

Look out for your future and see how well it can be ! Have pleasure doing so and experience and play with it . . .

Yours truly,

Thorsten Hassiepen"

Mark;

Try e-mailing Dr. Bleything here at Pacific University. He is the international liason for some optometric organization and knows many poeple all over the world. He is also a big force in the vision therapy field, so I am confident if anybody knew, he would. Tell him I referred you. His address is: [bleythiw@pacificu.edu](mailto:bleythiw@pacificu.edu).

Good luck.

Herb Black

I had posted not too long ago about improving my sight from -6 to -4.75 in  
about 4 weeks.. now I'm at -4.5 and I seem to have hit a brick wall..  
The past 3-4 weeks I have not seen any more improvement.

I have been a little depressed however (due to an ending of a relationship)  
and I think that may be part of the cause.

I'm wondering if the vision improvement I made recently brought out some stored tensions associated with the ending of the relationship (which happened about 5 months ago) because I wasn't previously feeling depressed and now I feel a lot better and like I've released it.

Perhaps the speed of vision improvement varies with the amount and distribution of stored past traumas & tensions..

I'm now even more excited and confident about getting on with the journey and reaching my optimum goal of normal vision.. without contacts!

[Lengthy quoted post deleted by moderator --AE]

Pete,

I also ordered Vision Freedom and have not seen definite results. I wonder if the book " How to prevent nearsightedness" claimed to have more technical depth will be of any value?

Vision Freedom is just a scam. From the Web page  
<http://see.visionfreedom.com/visionfreedom/summary.html>

Ophthalmologist approved, scientifically proven, Vision Freedom will rapidly reverse or prevent:

- \* NEARSIGHTED VISION (Myopia)
- \* FARSIGHTED VISION (hyperopia)
- \* ASTIGMATISMS (defective images)
- \* OLD-AGE VISION (presbyopia)
- \* LAZY-EYE (amblyopia, strabismus, etc.)
- \* KERATOCONUS
- \* CATARACTS
- \* MACULAR DEGENERATION
- \* DIABETES ASSOCIATED VISION LOSS
- \* TUNNEL VISION
- \* DOUBLE VISION
- \* GLAUCOMA
- \* and nearly any other vision disorder you may have!

This is fraudulent advertising. For some people, using plus lenses may reduce nearsightedness. But the V.F. claims are like buying bottles of aspirin for \$5.00 and reselling them for \$15.00, claiming to have some miracle drug that will relieve any physical pain, and cure the diseases that caused the physical pain.

The "eagle message" (Caroline quoting Thorsten Hassiepen) was just amazing.

First of all, I think there's a GENETIC rationale behind totemic cultural beliefs (deriving a tribe's origin from an animal ancestor). We have never lost the genes of all the countless life forms that went before us -- they are silently present in our genetic material, in the inhibited/repressed state, not different in principle from the way the gene for a future beard is present but inhibited in a newborn boy. We never lose genetic material just because we've acquired something new -- we merely inhibit it when we don't need it for survival anymore and when it's energetically "cheaper" to do without, to repress rather than maintain, certain organs or abilities. Even so, a lot of energy expenditures in a live organism's functioning go into PREVENTING things from happening -- into inhibiting our genetic capacity for developing full-blown gills and scales and claws and tails, into making sure we're only human, not human plus whatever else our genes are capable of making us. There were experiments on animals that showed it's possible to uninhibit a repressed gene after it's been dormant in a species for millions of years. In one such experiment, genetic material from a lizard embryo was introduced into a chicken's egg (don't ask me how). The chicken developed typical amphibian teeth, which are NOT what the lizard has but what evolutionally preceded the development of a bird's beak. Chickens were once pterodactyls, the flying lizards, and they never forgot the fact, not genetically, not even many million years later! The lizard embryo material acted as a key to unlock that memory (or, rather, an even earlier one, of the amphibian stage).

So... "primitive" shamanic practices may well start making sense if we consider this fact. Maybe what they are trying to achieve (and -- who knows -- sometimes succeed in achieving?) is a reversion of an inhibition on a genetic message. Maybe all they are trying to do is tap into some genetic

potential we all possess.

As always, the direction of my investigation was from a practical problem to a theoretical explanation, not vice versa (once a functionalist, always a functionalist -- never gave a damn for useless knowledge!) The reason I had to undertake some studies in shamanic practices was a vision-related dream I had, one that puzzled me a great deal. In that dream, I was watching a performing magician give a show in the town square. The magic tricks he demonstrated were amazing, and I wanted to take pictures. I was fiddling with my camera but the moment I was ready to take a picture, the magician would move so that I would lose sight of him in the viewfinder. It happened many times. Now the dream was in Russian and the Russian for a magic trick is "focus," for a "performing magician" it's "focusnik," and for getting things in focus when taking pictures -- well, it's "focus" again. So the situation amounted to my inability to focus because "focus" was, for me, some sort of a magic spell I was under -- it eluded me all the time, I just couldn't "focus" fast enough. So I called out to the "focusnik": "Slow down, I want to take a picture!" He turned to me and laughed. "Slow down? No problem," and with those words, he motioned his hand toward the sky. Time stopped. It was as though what had been a moving picture momentarily became a motionless hologram. I looked up. High above my head, an eagle was suspended in the sky, as though painted on its "surface," perfectly motionless. I could see every feather, and I could see an amber-colored eye looking right into mine. "Take your picture," the magician said, "and take your time, it's not going anywhere. Take your time."

When I woke up I understood all the puns the dream had mounted around the idea of "focus," but I didn't understand the eagle part (except that it also had everything to do with the problem at hand, "eagle sight" and so on), nor the part about stopping the time. I'm still not sure what it is that I was supposed to learn from my generous but elusive unconscious mind in this particular instance, but I don't try to hurry my understanding. After all, I'm supposed to "take my time!"

Elena

I have gone veggie and have noticed a calmer digestive track and i believe a simplified flow of moods. None of my annoying stray un-sourceable bad moods have occured since i started 4 months ago, and my theory is that the digestion of meat was causing them. You are what you eat (and absorb) and i have been taking that to its logical limit, wanting to avoid anything not fresh or sprayed or processed at all. It's satisfying physically and psychically.

Fasts are used by many to 'purge' and break out of ruts. If you feel like kicking yourself in the butt, go for it! I dont have any personal experience with fasting though. I do skip eating to feel actual hunger from time to time.

I'm trying to keep as vision-specific as possible, but the mechanics of the psycho aspect of vision is not as specific as the material aspects (and dont forget that the process of seeing is 2/3 mental)

>

Agreed. By 'consciousness' i meant the full gamut of sense described by

Elena and you. My point was that the thinking faculty is an inextricable part of \*our\* consciousness and as valid as the rest, so must be integrated. I think part of what Elena was saying was that Rational\_Mind does not control all things, but that it is a citizen in an economy of consciousness. The so-called mind over matter does become ridiculous when imagined as a simple decision that "reality is now this new thing i want" but consider that we all are discussing this thing called vision therapy(rational mind), modifying our behaviors and our \*belief structures\*(rational mind) and then seeing 'impossible' physical RESULTS. This is a valid example of mind over matter, the effort to subdivide the process into a description like; 'this is conforming your body to the 'natural' course intended for it' or any number of possible descriptions is also a rational activity. All paradigms are only mental constructs used to aid prediction. (Nothing is True)

OK, it's officially a digression now:>

>>But theory aside, i know that it works to remember incidents and question >>the conclusions i have held.

>

>I don't think the mechanisms are clearly understood, but only modeled >in various ways. I've heard of cases where someone's tension in >some area of the body will go away once they remember an related >experience and talk about it. The talking releases the energy locked >up (there is no past: it's all right here).

I've had this happen numerous times. I like your point about there being no past-very Zen! and very useful. It's thinking like this that creates breakthroughs in one's foundation beliefs, with surprising liberation of real energy. My explanantion of how past issues affect the present is that a -belief- is formed as a thought-response to an emotionally significant event. This belief persists and creates a boundary in one's mind, all current mental activity respects this boundary reducing the free-flowing of mentality or reduction of genius. (note that -belief- is distinct from normal rational behavior, it is an axiom which defies arguement) At this point a corresponding bodily restriction to energy flow is postulated, i would extend that beyond the body into our environment through our interactions and end up with the statement that our beliefs create our reality! (aka Karma)

>

>>Let's talk about techniques for putting the >>theory to work. Let's reclaim our vision!

>

>Lets!

I really intend this theorizing in the most practical possible way. This questioning of beliefs has born fruit for me in the form of increased

mental acuity and speed, physical health, and prosperity. ( empirical )

One technique i have used to explore my beliefs is to notice whenever i get mad at something someone says or does. I then i imagine that that was \*me\* who just did that and then i try to justify my acting that way. This leads to interesting discoveries. There are times when i cant imagine any way that i could have done something, these are the really deep and interesting ones. \*Much love and trust in oneself must be intoned when undertaking such activity or a danger of panic can happen. (Invoke your favorite Mother\_Goddess if it happens and She will smooth it all out again:):)

Richard Allen is one that I have a very favorable opinion of. I know him only through e-mail and Usenet discussions but he seems to be very knowledgeable and progressive. As a matter of fact, a sci.med.vision post of his as well as his name were crossposted to the list by an i\_see-er recently. Here are his whereabouts again:

Richard Allen BSc FCOptom FAAO DCLP  
Optometrist & Contact Lens Practitioner  
Colchester Vision Therapy Centre  
[Richard@eyescolc.demon.co.uk](mailto:Richard@eyescolc.demon.co.uk)

I believe Colchester is in East Anglia, somewhat northeast of London. Let us know if you get in touch with Richard and the results.

Good luck.

Stefan

I now include the quotes from the two articles by Dr's Orfield and Gallop. Enjoy and thanks for the interest.

Myopia Reduction - A View From The Inside

By Steve Gallop. O.D.

Paper published in the Journal Of Behavioural Vision, Vol 5/1994/Number 5/  
Pages 115-120

NOTE These are all quotes from the articles. This is copyrighted material and I share this as a form of education. Permission has been granted to me for this purpose.

\*It is my sense that it isn't so much the nearsightedness as it is the myopia that may be truly inherited.

Nearsightedness is the refractive condition which is typically compensated with concave lenses, while myopia is more about the tendency to shrink

visual and perceptual space and to restrict the musculature (and often the emotions) while attempting to solve the problem of responding to visual stress.

"The introduction of minus lenses is a procedure taken much too lightly in standard clinical practice. There are frequently ignored patterns of addiction to such prescriptions, not to mention subtle, slowly increasing changes in perception and behaviour."

Once the (minus) lens is applied, what is often a transient condition becomes a lifelong situation, one likely to deteriorate with time.

While compensating lenses seem to alleviate the problem (or symptom of blur), has there ever been a good controlled study to determine if the condition progresses in the same manner if such treatment is avoided?

Astigmatic prescriptions are optically highly structured and rigid and may cause added rigidity in the individual.

Concave lenses contract and constrict available stimuli, leading to a diminution of safe and usable visual, emotional and psychological space.

The dulling of sensitivity with too strong compensating lenses is one of the catalysts leading to mismatches in perceiving both the external and internal environments.

In myopia, there is often a tendency to emphasise and depend on external cues as a basis for decision making rather than trusting the inner voice.\*

Seeing Space - Undergoing Brain Re-Programming To Reduce Myopia  
by Antonia Orfield O.D.

Significant quotes from paper published in the Journal Of Behavioural Optometry, Vol 5.1994. Page 123-131.

\*Functional Myopia is not just an imbedded (accommodative) spasm and it is not just an enlargement of eyeballs. It is a reflection of the shrinking of the brain's space world by closure of the periphery, first by stress, then by errors in spatial judgement induced by minus lenses.

Children's space world has shrunk down to primarily central vision, so that they cannot judge distances. The (minus) lenses induce such warped vision in the periphery that their brains have to screen it out.....Lenses deepen their discolation in space.

Increasing myopia is a learned brain program.

(Visual) habits and the (minus) lenses have programmed their brains to think of vision as looking at something and seeing only that. To cure

myopia, one has to re-program the brain to see space.

Behind my frames, I was no longer in the world, but looking into it, instead.

The higher the (myopic) lens power, the more the periphery is warped by the lens, because light is focused for the benefit of foveal acuity at the expense of ambient vision.

The more the periphery is warped, the harder it is to see the centre clearly because you cannot judge how far it is without accurate peripheral cues.

I didn't know what was there for sure without my glasses, and with my glasses, I wasn't sure where the what was.

Space world is a mental perception of "how far is far" and "how deep is deep" and "how wide is wide." We can all measure 20 feet the same, but we all see that measured space in our own way.

Each minus lens has its own virtual world that is achieved by the interaction of the individual and the optics of the lens, and once one adjusts to that lens, one is looking into that world and has learned a new brain perception of spatial perception. The compressed view then continues one's need for the lens.

Lens reduction is truly brain re-programming.

The major changes in my vision were not so much in clarity, because one can obtain that in lenses, but in "volume" of space perceived.\*

forms of denial is addiction. We are addicted to many things in our culture, but I think our most dangerous addiction, and the one which all the others feed, is our compulsion for holding onto our beliefs. We're literally addicted to our ideas about the world even when we know they don't serve us.

We currently believe, as a culture, that it's just about impossible to be happy in life. We believe, in general, that it's a violent, cruel world. Most people believe that "something's going to get me, so it doesn't matter what I do to myself." We cling to people, boring jobs, money, dysfunctional religions, superstitions and other belief structures for dear life, as if it were those structures that are keeping us alive rather than choking us to death.

And we have, in particular, a way of holding onto the people who hurt us the most. These people may withhold love, try to control us, offer us things that hurt us (like if you're trying to quit smoking and your boyfriend keeps offering you cigarettes), or they may even beat, rape and abuse us. The belief to which people in these situations are addicted is that they're "trapped," or that they can't let go, don't deserve better, or they're too terrified of what would happen next if they stepped outside their nightmare and entered the stream of life.

Ultimately it's the belief that we're unlovable that is the most perilous of all. On the way to spiritual realization there really is just one thing we need to learn, and that is how to treat ourselves lovingly. This can be tricky because patterns of self-hatred go back so far into childhood.

Most people, I have seen, live in thought holograms of their own past. Again and again, like a vivid, 3-D video loop, life repeats itself, changing just enough to convince them that it's not the same. People caught in these loops see events in their own lives and in the world going in crazier and crazier spirals, and believe that history is doomed to repeat itself, or just doomed in general.

And they may even see this, and know and understand it.

What's less obvious is that whatever your reality, your mind, your belief structures and your values are creating it. People caught in a negative trip often walk around repeating to themselves, "Life is hard, things never change, I can't stand this, etc., etc." People for whom life is beautiful walk around saying things like, "This is fabulous, I have faith that things will work out," and so on. We don't realize that these repetitions, which in Sanskrit are called "mantras," are the primary support program for the "reality" we experience and see.

Life changes when we change. Energy around us moves when we move the energy within us, and that usually means working to remove blockages. We stop feeling so compromised when we stop making so many compromises. We stop feeling miserable when we stop choosing to be miserly with ourselves.

At this point, in August of 1996, I believe the human race is crossing a bridge, and that bridge is in flames. The bridge consists of our

At 12:48 8/9/96, Elena wrote:

Cool dream Elena! this 'take your time' message has been imparted to me on a few occasions and is a MAJOR key to an amazing vision known as Samadhi in the Buddhist system. A better way to say it may be to suppress linear time from defining your experience of the world. In this state all things inside and out occur exactly as they should and there is no angst or fear. The experience of 'synchronicity' is a flash of this vision, the vision itself is marked by everything being one continuous synchronicity. It is much more profound than can be expressed linearly.

The main implication is that the habit to NEED something to make oneself whole causes angst. Our common belief is that we are incomplete/imperfect and must make progress and get ahead and improve ourselves. This is essentially a time-based comparison contrary to the concept of fully experiencing the present. I'm sure everyone has noticed that seeing well requires the ABSENCE of effort. Also an absence of DESIRE, because desire implies an inability, paradoxically.

>I'm supposed to "take my time!"

The Eagle is a symbol of vision but is more specifically linked to the path of Scorpio-Atu Death in the Tarot. It represents the 'Higher Love' or

spiritual awareness. The vision i describe above implies a death to the Ego-as in the seperateness of yourself from the rest of the world. (Called heaven in Christian parlance). As beautiful as this state is, the interesting thing is that one inevitably begins to long for the confused state again, life is where the novelty is!

I have a small amount of myopia -- -0.5 D -- and a lot of astigmatism -- 3 D and 2.25 D. I asked the optometrist to leave the 0.5 D of myopia off my prescription, so my prescription was +0.5 D from the measured best correction. While looking around for frames, I used +1.25 D reading glasses to get by. When I picked up my prescription glasses, I saw 20/15 with them! It had been at least an hour and a half since I'd used the reading glasses. It's not clear yet if the effect is permanent. But I think people with small amounts of myopia may be able to fix it.

Dear Brian Severson:

In a message dated 96-08-09 13:55:54 EDT, you write:

<< My Dear Pete,

< I am in receipt of several of your messages to I\_see'rs.

<FIRST of all, I expect you to promptly retract your statement that I was  
<"unable" to describe the lenses to you. That statement is patently FALSE. I  
<specifically remember speaking with you as you attempted to obtain ALL of  
<the DETAILS about our program before you even "climbed on board" with us. I  
<will tell folks such as you "that question is answered in our kit", NOT "I  
<am \_unable\_ to answer that question".

My specific questions were "Are the lenses plus or minus, concave or convex"?  
Your answer was "I dunno, it's too hi-tech for me to explain, but you'll  
like 'em". When you asked me about my other ocular deficiencies, I stated  
that I had scotopia, convergence insufficiency, and exophoria. Your reply  
was: " I dunno what the heck that is but these special glasses will cure  
everything".

<I occasionally ((RARELY) get a call from someone that expects me to go to  
<great lengths explaining ALL of the details of the Vision Freedom program.  
I

<call them "weasels", as they expect something for nothing. NOBODY in LIFE  
<gets anything for nothing!!!!.... If you think that you can/do get ANYTHING

<for FREE in this World, you are living in a Fantasy...."What Goes Around  
<Comes Around" says it ALL.

The above stated question was the only one that I had about the kit. It's interesting to know that you think that your customers are "weasels".

<You, OF ALL PEOPLE should know (as a 43 year old student) that you have to  
<PAY TO LEARN. This is a MAXIM of Natural Law (Nature's Law) and cannot be  
<circumvented without paying the consequences.... Want to PLAY with  
Nature????

Brian, I think you need a pair of glasses when reading a calendar. The year is 1996, that makes me 44 years old. The best things in life and learning are free.

<You have a long way to go! Your statement on 08/06/96 "I think you can  
<duplicate the process at a more realistic price" shows me that you are  
<completely out of touch with REALITY. You obviously have no clue as to how  
<much it costs to start a Revolution....LOTS!!!! WE had to pay to advertise  
<so you could call us TOLL FREE (WE payed for all of the calls).

The response to Marco's question had nothing to do with starting a revolution. I want you to go back and reread HIS question to ME. Besides, I wouldn't call your company a revolution. A couple of centuries ago my forefathers started one without toll-free #s...just intestinal fortitude, a belief in God, and a musket.

<WE pay for the folks here to answer your calls..... WE pay for the printing  
<and postage in order for YOU to receive our FREE information....WE pay for  
<the printing and miscellaneous costs involved....And the costs go on and  
<on....It is EXTREMELY CLEAR that you have NO IDEA of the expenses and costs  
<involved in starting/continuing a Revolution. (And you NEVER will learn it  
<in ANY school....)

Maybe not, but if you want to be arrogant about it, after over 20 years in the United States Army Infantry, I sure do know how to ruin one. I also spent 3 years as a platoon leader of a counter/anti-terrorist platoon in Europe during the '70s. I was quite good at it too.

<EXACTLY how much is a "reasonable" cost for FREEDOM???? I think nobody  
<can/could put a price on how much FREEDOM is worth!!!!

You probably don't have the credentials to discuss "freedom" with me. After being in 2 wars, I've earned mine.

<On 08/08/96 you stated "I intend to read through the VF literature one more  
<time to see if there is a point that I missed, before returning the  
<kit."....For your information, you will be reading an outdated  
<revision....We would have been happy to send you the latest revision AT NO  
<CHARGE TO YOU, if you would have only had the DESIRE and/or Sincerity to  
<contact us....YOU NEVER DID!!!! (It would have been FREE, at absolutely NO  
<COST to you....You cannot SEE the forest for the trees....

Do you honestly expect your customers to call you every day about a revision?  
An honest businessman would have automatically distributed it to his  
customers.

<"Perhaps there is something that I have overlooked"....You bet there is!!!!  
<You are overlooking the BIG picture in Life. It may be a result of living  
in  
<Manhattan amongst all of the Sheep(1e), graft, corruption and vile.

I can SEE that spelling, geography, and agriculture are not your strong  
points. Manhattan is in Kansas where we still keep our doors unlocked and we  
are in the heart of cattle country.

<Now let's get on to some MORE of your FALSE STATEMENTS....You stated when  
<you "climbed on board" with us (01/02/96) that you were OD -4.00-0.75@005,  
<OS -3.75-1.25@008.  
<On 08/06/96 you "claimed" to I\_see'rs that you had improved from -4.50 to  
<-3.00 diopters "by reducing the negative stimuli". Either you LIED to  
Vision  
<Freedom, or you are LYING to I\_see'rs. (OR you are lying to yourself!)  
Which  
<is it?????

Upon receipt of your kit, I immediately made another appointment with my  
optometrist to obtain a baseline starting value. That is why those values  
were reported. Lighten up Brian, your customers are human beings, not liars.  
Ask before accusing.

<You also stated that "the quality of the lenses that are included in Mr.  
<Severson's kit is quite poor"....I challenge YOU to find a higher quality  
of

<lenses ANYWHERE short of going to an Optical shop (AFTER you have spent your  
<precious TIME and money locating an eye doctor that will prescribe what YOU  
<want....

I already had a pair of +1.00 and +2.00 lenses from an optical shop (prescribed) for studying when I was wearing contact lenses. I didn't need your glasses and I wouldn't have purchased the kit had you been honest about their contents.

<"If I encounter any obstacles, (returning the kit for a refund) I will <definitely post them." You will NOT encounter any such thing....YOU are <DEFINITELY not ready for us to help you YET....Maybe you will be in this <Lifetime, maybe NOT....If you find you are ready, WE'LL be here!!!!

Fine. I will return the kit for a full refund. But first, and merely out of curiosity, I will wait for the free revision that you will send to me. I still intend to be open-minded about this. If the revision is beneficial to me, then I will make a post of such information.

<And YOU, Marco...."Well - If he does refund your money with no questions <asked, then I would feel confident about getting the kit...."  
< And YOU, Marco then continued...."I'm sure he'll have a 'few questions', but  
< remember that you're the customer and that...."....Vison Freedom DOES NOT  
< have customers!!!!....We HELP folks, period. If you want (AND are Ready for  
< FREEDOM) We will help you....If you are not Ready YET, we will be here\_  
<When\_ and \_IF\_ you are Ready....

Leave Marco out of this. Your letter is addressed to me. This is between you and me, buddy.

<SEE you soon!....  
<(or Later, your choice)

<Brian

hello, group -

i'm glad someone finally wrote in saying that for them, palming was uncomfortable. I was beginning to think i was deformed. The very idea of palming for 20 hours makes all my bones ache.

I have tried all kinds of suggestions, positions and pillows but still i can't manage it for more than 10 minutes. I can happily meditate for hours, but the act of putting my hands on my eyes causes shoulder pain, and even wrist ache.

I find that when i have eyestain, the best thing for me is an ice pack on my eyes. Sometimes i palm and ice pack back and forth. This feels wonderful for me, and might be just the thing for some of you other non-palmers (you know who you are!)

Thanks to Bill for posting the article that hints how beliefs form our reality. I fully embrace this philosophy myself. In fact, i was investigating that theory when i came across vision therapy.

One book that describes the mechanisms behind belief = reality is called "The Nature of Personal Reality" by Jane Roberts. This is a book channelled by Seth, a very well-known 'previously alive entity'. I had a bit of difficulty accepting the idea of dead people writing books, but hey, he proposes an interesting theory. I'm not asking you to believe it, just try it and see if it works for you. There are other books, but i found this one to be the most accessible.

I was about 2 chapters into this book when he casually mentioned that all diseases, including the need for wearing glasses was based on a misconception of who we really are. Since i am a healthy person, i decided to challenge the theory using my eyes as a test case. I followed his suggestions and waited to see where the universe would lead me. Dr. Kaplan's book found it's way into my hands and within weeks, i had my first flash of vision. Before, i hadn't thought it was possible to change myopia so it wasn't. Then it was. And now my vision is different, not perfect yet, but at least i know it can be. And so it will be.

Since i read this book, my view of the world has turned upside down

and i'm much happier that way.

Just wanted to pass that on.

Hi All,

I seem to recall reading somewhere ( I think it was Dr Jacob Libermann's book 'Take off your glasses and see') about massaging the acupressure points around the eyes. I haven't tried it but I thought know might like to know that it has been suggested somewhere other than this mailing list.

It might also be in the Natural Vision FAQ.

Palming seems to be helpful to her a couple of times. She does not wear any glasses most of the time unless she needs to watch TV ( just a little while). She lost her most recent pair of glasses.

> I remember about a year ago (in personal communication) you said she had

Would this cause strain? I got her Vision Freedom reading glasses and  
tried to get her to read "Cross the Line", since she loves to read. But,  
she can not read far enough from the book, she can only manage to  
read the book about a foot away. What do you mean by DISTANT VISION  
PRACTICE??

> It sounds now as if she is going cross eyed.

>

Bifocal was recommended by two optometrists so far. But they gave two  
quite different prescriptions. One recommend 1.25 plus and another 2  
plus. Which to believe?? I heard it is better not to correct astigmatism  
in the lens, also, the prescriptions for both eyes better the same??

> I have some questions to help you decide what you can do, what

>

> 1. How old is your daughter?

>

10 year old.

> 2. How far can she see absolutely clearly without glasses? That is, at  
> what distance do things start to get a little blurry?

>

She can see one inch size character about 5 ft away without glasses. What would this be in terms of 20/20 terminology? She can not see the next line without a little blurry.

> 3. Is she comfortable without glasses?

>

During the day she is alright without glasses, she even plays tennis without glasses. But she does have the tendency to squint for something she is interested in seeing. Should I get her pinhole glasses?

> 4. At what times of day can she see well, at what times of day does she see poorly?

Don't really know yet. I do know for myself, when first waking up, it is the best time, it could be two lines better.

> 5. How much time does she spend outdoors each day?

For the past few days in the camp, she is outdoors about 6 hours a day. But before the camp, she likes to stay indoor to read.

> 6. What is her attitude towards vision improvement (very important)?

She is really anxious now to get her eyes back in shape. She is even willing to drink carrot juice and the chinese herb ( KaoChiZi, don't know the real name, just pronunciation, suppose to be good for the eyes) tea.

> 7. Did your optometrist ask these questions?

Some. I went to Dr. Ben Lane in NJ. He seems to know nutrition and eyesight, but did not give me any guidance about how to improve her sight. My daughter's dietary analysis seems to show she had too much protein and refined carbohydrates.

I used to think myopia was a normal biological variant which was genetic. Glasses to the myope were sort of like high heels for a short person. Now after reading more about it on my own (no thanks to my eye doctors) I find myopes have more glaucoma, more retinal detachment, more vitreous degeneration and a thinner eye wall. That's not a normal variant! One source said myopia was the sixth leading cause of blindness. From the more detailed texts, this is better described as a pathological stretch, rather than a growth process. From the epidemiology, it is cultural. Some people are probably predisposed to it. Then you add the modern lifestyle, whatever the factor(s) are, and the eye stretches and tears. The visual acuity problem is only part of the picture.

I have not done an extensive search for present research on the etiology of myopia at the pathophysiological, molecular level. I just got the order form for the Grateful Med stuff, and have a few names in the field but I haven't gotten much beyond that. One medline a friend did had 408 references to research on myopia (research done by M.D.s or in the field of ophthalmology, there was very little on optometry). About 400 related to the laser surgery. It looks to me like the medical profession didn't finish their homework before going ahead with this corneal surgery.

I think if you really look at this condition, what you really want to do to successfully treat or cure myopia is to reverse the stretching process. I think the funding for research was very generous in the direction of the surgery. And the herd went in that direction. It's a big money maker. Now if someone figures out how to reverse the stretch (and I don't think VT has studied this aspect of myopia, the papers usually report changes in visual acuity and refractive error, but say nothing about the overall health of the eye, it would take a huge long term study and lots of dedicated people, maybe along the lines of the Framingham studies on heart disease) and you have already had the laser, you're in a pickle. Knowing what I know now, I'll

pass on this surgery. I'm going to do some more medlines and see who is researching at the root of myopia at present.

I think the real root lies in my lifestyle but I still have to support myself and can't spend all day outside, which is what it might take. I also think the field of energy medicine, chakra points, (Bates' swinging reminds me of a kundalini yoga exercise intended to open up the heart chakra , and the heart and brow chakras correspond to the eyes) mind-body stuff is in it's infancy in my understanding and I am open to exploring the possibilities there too. I'll just pull down all the shades when I do that swinging 'cause I feel like an idiot. I hope that answers your question about why I think myopia is a disease. I think it is unfair and unethical to do this surgery on people without making sure they have all the information necessary to decide for themselves is this is really such a great idea.

julie

# Vision Freedom

---

- *To:* [i\\_see@indiana.edu](mailto:i_see@indiana.edu)
  - *Subject:* Vision Freedom
  - *From:* Brian Severson <[vision@visionfreedom.com](mailto:vision@visionfreedom.com)>
  - *Date:* Sun, 11 Aug 1996 16:27:47 -0600
  - *Sender:* [owner-i\\_see@indiana.edu](mailto:owner-i_see@indiana.edu)
- 

My dear Pete,

Because of the length of your last message (08/10/96@19:42:05) I have left it behind and am replying anew.

Your question to me was NOT "Are the lenses plus or minus, concave or convex?".

AND my answer was NOT "I dunno, it's too hi-tech for me to explain, but you'll like 'em".

AND I did NOT reply to you "...but these SPECIAL glasses glasses will cure everything".

You seem to enjoy fantasizing about what comes out of my mouth. Haven't you got better things to do????

(I certainly do....)

We do not have "Customers". If you want HELP, (and if you are ready for it), I will HELP you.

I am certainly not afraid to call a "weasel" a weasel. (Nor a "spade" a spade.)

Congratulations on your 44th birthday....If I would have known your birthdate, I would have "done my math" perhaps more correctly....(I have beter things to do....)

I have not gone back and re-read Marco's question to you.

Go ahead and be as arrogant as you want. Congratulations on having spent over 20 years in the Army, and 3 years as a platoon leader protecting us from counter/anti-terrorist's. I am very Happy for you that you were "quite good at it". America will need your talents when the S\_\_\_ hits the FAN in the very near future....

I am very happy for you that you have earned superior "credentials" to mine concerning "Freedom". I am also delighted that you have survived 2 Wars. I'm certain it was meant to be, as ALL things are "meant to be".

Please EXCUSE my spelling, geography and agriculture mistakes. "It's O.K., Dorothy....We're not in Kansas any more".

I am glad for you that you already had several pairs of prescription + lenses before you received ours. I am certain that the quality is far superior to our's, and that you paid less for them than ours....

You accuse me of not being honest about the contents of the vision kit....YOU are the one that needs a Reality check here!

I will take you up on your statement "Fine. I will return the kit for a full refund." Please insure it at your Post office for a buck and some change so there is no dispute that it got to me, and address it "Attn. Brian".

I will NOT send you the newest revision. You will be waiting a long time for it. Return your kit.

"I still intend to be open-minded about this."....You have already clearly demonstrated you are not.....

I am not interested in you "making a post of such (beneficial) information"....

I have left Marco out of this...."This is between you and me, buddy."

Thank you for "shedding quite a bit of blood" so I can enjoy "real freedom". I am Proud of you. (A lot of folks might not appreciate your service to America out of Ignorance.)

SEE you later!  
-Over and Out-

Brian

> myopes have more glaucoma, more retinal detachment, more vitreous  
> degeneration and a thinner eye wall. That's not a normal variant! One source

That is interesting! I suppose, though, that a weaker organ will naturally become more susceptible to any ailment - just as a person will more likely get a cold when they are tired and run down.

> you really look at this condition, what you really want to do to  
> successfully treat or cure myopia is to reverse the stretching process. I

I agree. I think vision problems will likely not go away for people who get laser surgery, unless, perhaps, they take up VT. Otherwise, what's to stop their myopia from resurfacing?

I've never thought of myopia as a disease before, but rather as the eye(s) being "weak" organs that need rehab. I still tend to think this way, however, my right eye went myopic many years before more left one did (when I started to wear glasses part time - mainly for driving, at age sixteen). Why my right eye went myopic in childhood while my left eye stayed at 20/20, I don't know. My left eye went myopic, obviously, due to the glasses, and my forgetting how to see properly, as a result. So was it a "disease" that caused myopia in the right eye, and a physical condition for the left?

Julie: The reason you don't find much from optometry about myopia in Medline is not because there are few studies done by optometry, but because Medline is done by The National Library of Medicine in Bethesda and they did not include any optometric journals until recently and then only a couple. I lived and worked right near there and spent many hours in the library doing research so I know wherof I speak. That is a real problem when MD's tell patients there is no literature about VT, what they are really saying without knowing it probably is that Medline does not show it. BUT, if one were to take the trouble to search the optometric, educational, and psychological literature, which in my opinion is every bit as valid and relevant as the medical literatute on the topic of VT, he/she would find lots of studies.

For now, I will tell you that the University of California at Berkeley is doing a huge study of myopia in school children. They are measuring lots of different parameters about the eye over a long time period. I don't have access to the reference right now since I am studying for my National Boards (tomorrow). I worked at Berkeley opto school last summer as a research fellow and met many of the people on this study. They are very qualified researchers- many are OD/PhD's with much experience. I would encourage you to look into it.

snip

> acuity and refractive error, but say nothing about the overall health of the

>only part of the picture.

The modern lifestyle seems to me a worthy thread to follow. I will list some things i believe to be destructive environmental factors. I like to hear any and all rebuttals to my opinions (because sometimes just a bias against the factor can cause the stress-not the thing itself!) And also to hear of other factors. We heard about salt from two perspectives and i feel i'm up a little on that issue, i never thought about it before. Same with aspartame (though i never used it out of my general bias against consuming strange chemicals).

I'm rather pessimistic about the quantity of unhealthy things in our modern lifestyle, but this is where all my friends are, so i'm not going anywhere. I'm hoping to at least identify ALL of the worst ones and figure ways to avoid them if necessary.

Ones that spring to mind: cheap dieldrin and scented soaps (skin absorption), processed and chemical-laced food products, sprayed and chemi-fertilized foods, automobile exhaust, manufacturing exhaust, plastic/vinyl off-gassing, press-board off-gassing, stray chemicals in water supply. These cover just about everywhere i go and do. it's easy to get overly-concerned about things that don't create a huge problem if simply ignored. But these are known risks and i'm happier facing the facts than to practice denial. The body does have regenerative powers, so perhaps all of these things in small doses can be handled. My plan is to avoid what i can and leave the rest to Fate while trying to raise consciousness whenever i

can-maybe my kids will have it a little better.

I didnt even touch on the psychological stresses; job security, belittlement by superiors, sexual oppression, denial of societal wrongs... these are as real and destructive as the chemicals, maybe even more so because they bring ones spirit down which lowers resistance to malevolent influences. And these are pervasive, just sensing others lowered spirit is a stress, and there is no cultural training to handle this vital area--most dont even acknowledge 'spirit' as a part of us!

This would have to be my biggest problem with modern life; excessive reliance on logical explanation and its corresponding undervaluing of feeling. Re-balancing that in oneself brings all the systems back on line, making avoidance of stresses automatic.

A person with 20/20 vision should be able to see a one inch high character at a distance of 57 feet. This would make your daughter's vision a little worse than 20/200.

I can kind of see your point about not calling myopia a disease, but I kind of don't see it too. It's a fine point. So if someone has narrowing of their coronary artery, they don't really have a "disease" until it spasms or clots shut and they have a myocardial infarction? Just the narrowed artery is OK? The real disease is the heart attack. Yes and no. Same goes for hypertension. Most of the time it is asymptomatic. It's not the high BP that's the big deal. It's what that pressure does. Stroke, heart attack, renal disease, impotence, etc..

I was told my eye grew too long. The axial length outgrew the focusing capacity of the eyes. Too bad but no big deal. Irreversible, genetic, not environmental. But from my reading, this is incorrect and simplistic. The treatment option in the past was lenses, now I can have surgery. I was never informed of alternative treatment options. I was never informed about research for future alternative treatment options. Again, I think myopia is better classified as a disease as opposed to a normal variant, and I'm passing on the surgery. Feel free to enlighten me. I'm waiting for a good explanation.

Indeed! I had another thought that fits with this, after i wrote about feelings being undervalued this morning, it occurred to me that seeing is a \*sense\*, which is a 'feeling' activity rather than a logical/reasoning activity. I began to try and 'feel' the visual space. This produced an excellent result and it was much like the 'continuum of light' vs.'object-orientation' i wrote about a few days ago.

How this fits into your statement is that by FEELING, one is \*involved\* as opposed to the disconnection possible by the objectifying of the world.

This objectifying could allow one to insulate oneself from the world around us. This seems to corroborate some of Dr.Kaplan and Elena's words in other posts.

Yes, I know exactly what you mean. When I remember  
this I get simultaneously, greater involvement and  
greater detachment ("in the world but not of the world",  
and so on). It's instantly energizing and raises my  
spirits.

Howdy Fello Vision Compadres (and Comadres),

Again this morning I noticed something very (very) interesting. A few minutes after waking up (some 20 or so) I decided to test my vision (sit down on couch - if I can read clock on VCR - my vision has improved since I usually cant). The results of sleep are (in my case) very dramatic. Unfortunately I do not have any hard core measurements, but I can see an increase in acuity. I notice that the acuity deteriorates as the day goes by.

I would speculate that that is because I am relaxed, have slept an what not. But I wonder if there are other reasons (hormones present in the morning or during sleep) or anything to the alike.

If anyone in this list has a similar experience please share!!!

Dr Kaplan - Has your research shown anything like this? Seen it in any of your patients?

Cheers to all!

I\_seers.....The recent discussions regarding the role of the mental component associated with vision have been very interesting to me. Have you ever considered that, as myopia progresses under the influence of minus lenses, the minus lenses themselves should exert a "plus lens" effect as they become inadequate to correct the increasing myopic defect? If plus lens therapy alone could reverse myopia, then there would be a push/pull effect that stabilizes the myopia at the level the lenses corrected. That is, as the myopia progressed, the lenses would become more plus, and should theoretically work to reverse that trend. But that clearly does not happen. There is a component that has been overlooked, IMHO. For instance in my own case, when I decided to begin VT to reverse my high myopia, I had been forced to remove my left lens due to intolerance by that eye. As my left eye improved under the Bates program, the visual acuity in my right eye improved in the same proportion. Even though the right lens was still being worn, and I was not trying to apply the method to that eye. In fact it seemed that my vision in my right eye was deteriorating, but I found when my acuity was actually measured that the lens in the right eye was now overprescribed by more than 2 diopters! When I first posted my case on i\_see several folks asked me what I had done to achieve my improvement, and I responded, quite candidly, that I had done nothing other than use the Bates method. After following the recent discussions on i\_see, and reflecting on my own progress, I have come to realize that I had indeed been doing something else. I had changed the mental component of my vision dramatically. I began my quest with the INTENT to see things

clearly. When I palmed early on, it was with the intent that when I opened my eyes and looked at the chart, that I would see the letters more clearly. And I did. Later on, as blinking largely supplanted palming during the day, I also blinked with the intent that my vision would sharpen. And this has largely been the case. Sometimes it takes several blinks to get a sharp image. I am consciously sending a message to my brain that the image I am seeing is not adequate, and when I open my eyes I intend to see better. Initially my clear flashes either quickly faded, or were too painful to maintain, forcing me to close my eyes. But gradually what I call my baseline vision has improved almost imperceptibly, to a level approximately three diopters better than when I started. My comfort level has improved in parallel. As I move about during the day I look at my wall clock, or street signs, or notices with the intention that I will see them clearly. This has progressed to the point where currently I can relax the tension around my eyes, send this mental message and get an additional slight improvement even without blinking most of the time. With this realization has come accelerated progress as well. An exercise that I have been using lately is to read the numbers on the clock face one by one, three times around, while seeing them progressively clearer. With each eye singly, and then with both eyes. And so I have come to realize that my mental attitude toward my visual acuity is terribly important. I have come to believe that this is the single most important aspect of my VT progress.

Ted

I am about to turn 41 and have worn glasses since about 15. I work in a technical area, not medical, but have read traditional and non-traditional books on the eyes over the years. I agree with Julie, that myopia should be considered a disease and I wish it would be by both doctor and patient. The sad thing is that most eye doctors are not educated to see it as such. Most patients depend on their doctors for education. They are not made aware of potential long term detriments until their risk becomes high enough, as deemed by the doctor, who basically believes there is nothing to be done but prescribe stronger lenses.

In this discussion, some people are playing games with semantics on just what constitutes a disease. Consider the semantics involved with a doctor, someone who is an expert and whose statements you should be able to trust, telling you have a condition that is common and merely an inconvenience. Now consider being told you have a disease that is associated with and may cause permanent damage in the long run. Do you have different reactions? I think so. The connotations of 'disease' are negative and I think that is how myopia needs to be viewed, as something that needs treatment of the cause not just symptoms, such as prescribing glasses.

Julie, I think you are absolutely correct in not having lasik, RK or any such surgery. It does not treat the cause of the disease, only a symptom. The research grants have gone to these kinds of quick fixes.

What's the real answer? It is not simple. I do feel the exercise techniques, Bates, VT, and proper nutrition have helped to halt the progression and reverse it a bit. But it is a long road and there will be few conclusive cause and effect events. I've read in a basic ophthalmology text that myopes often progress and then back off a little when they hit middle age. I think this is one of those life situations where you trust yourself and go with what feels right. Basic lifestyle and stress reduction are also strong factors. Just as there are personality types for heart disease, I think they exist for myopia, especially moderate to severe.

Brad

Marco,

I have exactly the same experiences. I am in my forties, and started to have slight old age sight along with my myopia. I remember someone mentioned morning eyesight is usually better for such people, but I don't remember any reasoning behind it.

Although I heard if I wear glasses during the day then I might keep the same eyesight at night. I don't know about this. I don't wear glasses during the day most of the time even I have -3 myopia.

>What are the main differences between Power behind your eyes and Seeing  
>without glasses? Could you post the table of contents, or providing a  
>brief description?

Seeing Without Glasses is a practical workbook for developing vision fitness. It is very easy to follow a three-phase training program, a mix between Bates and conventional vision therapy. Mingled with this are case studies.

The Power Behind Your Eyes is the second book written to share the deeper understanding of vision from an emotional/metaphorical and spiritual point of view with in depth case studies and specific written and exercise approaches.

>Mei-Tien

The 20/40 vision fitness lenses let you monitor how your mind, thoughts, effectiveness of your vision practices and feelings affect your eyesight. I am not sure at this point whether the eye muscles are involved at the beginning, certainly lots of perceptual changes. I feel we can and do relax these muscles but the new research seems to implicate a field of energy around the muscles, skin and body that changes sooner than the actual spindles in the muscles. I refer you to the work of Valerie Hunt in her book The Infinite Mind.

Marco, this is not an uncommon experience. I am curious if you have tracked your dreams prior to these clear flashes. I have seen situations where the dreams can help clear the past emotional blocks and this frees up mental clearness that programs the eye to see clearly. Again I emphasize to all the importance to pay attention to the clarity of eyesight rather than put all attention on trying to change refractive dioptric numbers like the nearsightedness or astigmatism. Try an experiment at night by lying quietly and pretending in your mind that you can see an eyechart perfectly clearly, like at an earlier age. Then see what happens in your dreams and the next

morning. I had a client recently who told me she had a dream and saw herself not wearing glasses in her dream and the next few weeks produced big improvements in her naked eyesight.

Thanks for your post.

I remember that testosterone levels are highest in the morning, after a good night's sleep. I have also noticed this morning phenomenon (yes, women have testosterone, too :). I also notice that at the times my vision is sharpest, I have thoughts/feelings of being strong/capable, etc. (this state is also associated with elevated testosterone). Some researchers with too much time on their hands once tested men before and after they played competitive games. The players who won experienced a significant rise in their testosterone level. Those who lost didn't. Hmmmm....

There are probably other, as yet unidentified chemical happenings at work in the morning, too. I just wonder if it is a case of "which comes first the chicken or the egg?" Do the chemicals appear because we are rested and feel good? Do we make the happy chemicals and then feel good? Hmm.... Do I have to win a game, or is it enough to be satisfied with myself and my performance?

Mary

Mei-Tien,

I haven't seen any articles regarding myopia and the use of glaucoma medications. When I get some new software, I will be looking at the medlines to see if I can find anything. Ideally, I think you would want a medication that would relax the ciliary muscle and contract the iris. Natural sunlight does that, pilocarpine contracts both muscles at once. I think lighting may be a major factor in myopia and the research seems to ignore this as a possibility. One study noted that when schooling was introduced among an Eskimo population, the kids had nearly 50% myopia, their parents 5% and grandparents, none.

I have a really spotty VT program. I am reading with reading glasses (sometimes, but at least I no longer read with the negative lenses), doing focusing exercises (sometimes), trying to spend more time out in the sun, taking Bilberry and EyeBright and just starting to do some palming and other accutouch type stuff. I have large pupils and I think I am getting these clear flashes because I am getting some voluntary control of my iris, being able to contract it for distance viewing. Or at least maybe it's not relaxing as much. You are not supposed to be able to do this, but that is the best explanation I have for what I feel and see. I tried some accupunture but did not notice a big difference. Per WHO myopia in children can respond to accupuncture, but I have no references for this. The biggest difference is when I spend time outdoors. Sometimes it is so clear and wonderful I feel like I am hallucinating. I dropped 1 Diopter in the first 6 months but have not had a measurable improvement over this last year. I do get more of those clear flashes though, but this fluctuates. My acuity bounces all over the place. I plan to move in the next year to a place with more windows and sun exposure. I'm also reading more on energy medicine and plan to take this a bit more seriously. Supposedly the prana comes from the sun, comes with the light rays. I think since we can't measure prana well,

it would be hard to know that myopia is not a prana deficiency. Obviously my eye can at times see very well and this is pretty much instantaneous. I can't think of anything besides the eye muscles that could account for what I am seeing. I saw an OD a few times and she said I had lost my focusing reflex. I think with time I can get most of it back. With pin hole glasses I could see 20/30. If I can tightened up my iris, that will make a big difference.

I don't know if it's because I'm not a 'morning' person or because my dreams are very adventuresome or what - but my morning vision is far worse than at any other time of day. I take a long time waking up, don't feel right till around 10:30 or 11:00 am and my eyes are in agreement with my mind. They begin to see as I awake. This has always been the case and is especially so since I entered the so-called presbyopic state (so-called by me here now not by anyone else so far as I know.) btw, my presbyopia and right eyed astigmatism are approaching the negligible state after several months of exercises - a combination of behavioral optometry and natural vision. And since I have been on bilberry also - who knows if that hasn't also played a part. And then there is the ineffable effects of everything else, both positive and negative.

Just couldn't hold saying that I entirely agree with you. I have reached the same conclusions and couldn't have said it better myself.

```
>Have you ever considered that, as myopia progresses under the
>influence of minus lenses, the minus lenses themselves should exert a
>"plus lens' effect as they become inadequate to correct the increasing
>myopic defect?
```

This is true but how much should myopia progress before this effect sets in? Given that most ODs do not warn against using distant prescription for near, in children one would expect about 3.0 D uncorrected myopia to be sustainable.

There are further twists to the mental side of things (I should have dedicated an entire post but anyway, briefly while I am at it). Let's go into the future. I'll assume most will agree that minus lenses giving 20/20 do not help improve vision. Imagine we all achieve 20/20 thru VT. Then we have the same effect as a lens 20/20 correction. By that time we should be

addicted to plus lenses as the only way to counter the societal demands for close work. Another dependency. I am sure most of you know people who do a lot of close work and yet see fine. They are not that few. I guess at this point in the future (and somewhat before) we should issue a command: "See 20/20 without glasses and do not deteriorate". If our mental powers are that strong, this should work. Until then we are primarily in another mode "Gain in acuity".

Seers,

The last couple of days a new dimension has been added to my peripheral perception. I mentioned a couple of weeks ago that seeing a 'continuum' of light rather than a lot of objects was helpful. Then i mentioned earlier in the week that i was 'feeling' the visible field with my eyes, this added another level. Now i have noted a new thing; the objects that i do recognize are starting to reveal an intrinsic dimension. I do not mean perspective and depth as a linear thing, but rather i feel i am seeing -into- their existance. For example, i first noticed that as i was scanning a bulletin board in my house, i was noticing the objects and instantaneously seeing their history as well as their shape. The Colosseum was recently posted from a friend travelling in europe and the picture flashed all kinds of thoughts, her purchasing it at the gift store and writing on the back and mailing it and that whole line of thought-all from a glance at an object. This way of seeing things opens up a different level of perception and has made the acuity much more 'necessary' and 'available'. Has anyone tried to keep 'scanning' as advised by Bates, but not known what to look at? isnt it easier to just think about something and not worry about keeping your eyes moving? Well this is a way to have an infinite amount of reverie material inspired by the exterior world. The doorknob is brass and old fashioned like this house, through the window is a flower pot with herbs and the plan to build that new plot for a bigger herb garden, herbs are such a source of healthy things, i wanna grow some eyebright!

A theory comes to mind. What if the stress layed on the school kid is more acutely fealt in the form of lessons which do not match the child's vision of reality? What if this causes one to not 'trust' their native intuition

and feelings about subjects. No question that individuality and creativity is discouraged in most any school. Even art classes rarely emphasize this. My daughter was in tears one day when she told me about how the teacher dismissed her interpretation of a poem as -wrong-, she couldnt figure out why she was wrong, nor could she figure out what about the teachers interpretaton was right. I questioned her and read the poem (i am pretty good at poems) and found her interpretation valid and tried to explain how the teachers interpretation could be taken, though i honestly thought hers was more consistant! I've been trying to remember what kinds of lessons caused me stress in this way.

The point of this is that there is a tendency to objectify things as a goal over subjective experience. In this way, we may see the world as a lot of objects with independent objective existance and ignore our relationship to them. It is an interesting philosophical arguement to consider the existance of anything one cannot personally percieve by some means. Regardless of the outcome of this debate, in practice we are intimately involved with the process of perception and this suggests that vision disorder may be a result of some form of disconnection from our own 'feelings' about the world. Come to think of it, there's plenty going on that everyone just would rather not see, which expands my theory beyond the walls of the schoolhouse. Certainly glasses symbolize a barrier between us and the world.

Hello fellow ISEEers,

It's been almost 2 months since my last update. The delay was due to a long trip overseas and to some heavy work load. Now I'm sort of back to normal life.

For the last 2 months I have not been doing any exercises although I maintained a good level of looking after my vision. Unfortunately, during the trip overseas I had an infection in my right eye which lasted about 4 days and then came back to normal after using some eye drops.

anyway, yesterday I went to my optometrist for the usual checkup and the result is still the same as the last time.

Below is my progress so far:

|          |       | Left  | Right |
|----------|-------|-------|-------|
| 18/01/96 | -3.00 | -3.75 |       |
| 17/02/96 | -2.50 | -3.00 |       |
| 16/03/96 | -2.50 | -3.00 |       |
| 19/04/96 | -2.25 | -2.75 |       |
| 25/05/96 | -2.25 | -2.75 |       |
| 17/08/96 | -2.25 | -2.75 |       |

Lately I have started thinking about my next step in improving my vision and currently I'm contemplating 2 options:

- 1- PRK (laser surgery)
- 2- OK OrthoKeratology

I have read all the stuff that people have posted about PRK and by the way

congratulations Mario on your surgery results. I have 2 problems with PRK:  
1- the info that I received from the different clinics say that to be a good candidate for PRK your vision should be stable for the last 12 months. Mine hasn't been!!!  
2- the cost. In Australia, it costs between A\$1,750-A\$2,250 per eye. That's a LOT.

The other option is OK which my optometrist only told me about yesterday. Below is a brief description of OK (found somewhere on the Net):

.....This new program uses a series of different contact lenses to gently, and painlessly reshape the cornea and improve your vision. The procedure is safe, effective, less costly and has satisfied thousands of patients including a two-month old baby diagnosed with nearsightedness.

Gradually a person's vision will improve (a few weeks to six months) and after the rehaping process is finished, a pair of retainer lenses are prescribed to maintain the cornea's shape. These lenses are worn just a few hours a day or week, generally at night, to maintain the ability to see clearly without the need for glasses or traditional contact lenses.

Myopia or nearsightedness, is the most common vision problem found in the US. The condition worsens in the teenage and young adult years even if the person is wearing contacts or glasses. The Ortho-K lenses are beneficial because it can prevent further vision deterioration if the condition is diagnosed early. By catching nearsightedness in the early stages (around age 10) children's eyesight can be saved from deterioration.....

OK seems logical to me and its cost is relatively cheap. In Australia it costs about A\$1,250 for both eyes.

Now my questions are:

- 1- what do we know as a group about OK?
- 2- has anyone tried it?
- 3- does it work?
- 4- how 'permanent' is the improvement?
- 5- is it safe?
- 6- why aren't people talking about it?

that's all from DownUnder. Good to be back online.

Ow -- that *\*hurts\**! I believe you've pinned the stress thing down with this  
example. This is exactly the sort of thing that makes children dread  
lessons. How on earth can something as subjective as poetry (etc. etc.  
etc.)? How sad that this teacher seems to have no ability to tune into the  
students.

>I questioned her and read the poem (i am pretty  
>good at poems) and found her interpretation valid and tried to explain how

*\*I\** can't *\*forget\**! Mine tended to be in math class. I remember standing  
outside an Algebra teacher's class in 7th grade, mesmerized by his crystal  
explanations and the instructive interaction, and wondering why that never  
happened to me. When I tried to transfer into this instructor's class, I  
was told that my name started with the wrong letter and I was stuck with  
whomever I got. When I graduated from high school I couldn't do long  
division! School is not designed for the students!!

And it's amazing how much stock we put in them! (As crucial possessions as well as anything else) I remember my grandmother telling me that my eyes would get bad very quickly if I insisted on reading without them (I'm nearsighted). Luckily, I had this looney idea that she and my mother and the doctor and my teachers were wrong, and only wore them when I \*had\* to. The pressures come at children from all sides. Sorry for this bit of ranting (I shouldn't post when I'm tired!) but that letter really hit home! :)

>6- why aren't people talking about it?

The big challenge I see George is that you are monitoring your vision improvements by studying the dioptric changes. In my experience these take much longer to change than visual acuity and what actual lens prescription you are wearing. Both laser surgery or corneal remoulding are usually only physical attempts to recalibrate the shape of the myopic eye without addressing the fundamental cause of the eye condition in the first place. I have practitioner reports that PCM (Precision Corneal Moulding) or what used to be called Orthokeratology works well when a holistic approach is included such as I and others have been reporting to this group. If you are near Victoria go and see my friend Peter Fairbanks in Ballarat. He is a very progressive Optometrist who will steer you in the right direction. I could meet with you when I am there in March, 1997. All the best,

Robert-Michael Kaplan. O.D., M.Ed., FCOVD

Dear Seers,

I am looking for an introduction to a person capable and interested in presenting the alternative Ophthalmics to an annual meeting of good folks involved, conversely at the cutting edge of high tech and imaging technology.

If anybody knows or can direct me, I would be most appreciative.

Thanks in advance,

Ethan Priel

Linda

I thought I was deformed too, hence my delay in appearing to criticise what everyone else seems to rave about!

I also have problems in seeing any benefits of it (in terms of clear flashes or whatever), although it does remove eye strain for a second or two and I have no doubt that it OUGHT to help.

I've found one comfortable position this week, just in case you are still trying. I lean forwards with my elbows on my knees (ie lower than a table) with my knees parted a bit. (I started to fall asleep in this position when I tried it for 5 mins or so, which may have defeated the object!)

Caroline

hello, group -

i'm glad someone finally wrote in saying that for them, palming was uncomfortable. I was beginning to think i was deformed. The very idea of palming for 20 hours makes all my bones ache.

I have tried all kinds of suggestions, positions and pillows but

still i can't manage it for more than 10 minutes. I can happily meditate for hours, but the act of putting my hands on my eyes causes shoulder pain, and even wrist ache.

I find that when i have eyestain, the best thing for me is an ice pack on my eyes. Sometimes i palm and ice pack back and forth. This feels wonderful for me, and might be just the thing for some of you other non-palmers (you know who you are!)

Robert

Does this mean that you would expect to see an improvement in your ability to read an eye chart unaided before you'd see a reduction in the correction required in order to achieve 20/20 vision?

>activity.
```

Right! If anything about us at all is a sense it's vision more than any other function: 70% of our body's total number of sensory receptors are located in the eyes. Meaning: 70% of what we feel or fail to feel happens (or fails to happen) through the eyes. (No wonder myopes are bent on reasoning -- it's a compensatory function!) A pit viper perceives electromagnetic frequencies all the way across the spectrum from infrared to ultraviolet -- that's why it doesn't need to wait for a "scientific discovery" of the existence of electromagnetic phenomena beyond visible light -- it just lives them -- doesn't have to take anyone's word for it.

The eyes are physiologically equipped to feel, not to reason. That's why I've been trying to make this point over and over again: don't communicate with your visual system in words, beliefs, ideas, scientific concepts, and so on -- that's its second language at best and most of your arguments will be lost in translation. Communicate with it in its native tongue of light and darkness. Present it with the arguments of shape and distance, shades of color, contrasts and outlines, movement and stillness, nourishment and rest. Don't TELL your eyes anything -- listen to what they tell YOU, in their own language of clarity and blur, pain and pleasure, tears and dryness, seeking and avoidance, volition and spontaneity. It's a simple language to learn -- a lot easier than any foreign language, since it's not foreign, it's our own... even though our natural proficiency has been lost at some point. (The natural scientist Konrad Lorenz refers to our loss of ability to understand the language of our own species-specific instincts as

the "abnormal and pathological process of domestication of humans.")

Not a single message our feelings are communicating to us is unimportant -- we must connect our understanding to where they're coming from in order to function properly, and the connection has to be precise. It's your eyes, not your ideas, that can explain to you the PRECISE mechanism that switches on a myopic response. What is more, they will tell you all you need to know in order to switch back. Mine did. Ideas will follow -- in an upside-down waterfall from the depth to the surface of your mind -- but feelings come first.

All it takes (not in the sense it's easy -- in the sense it's sufficient) is retrieve some personal history dating back to the time when you were a totally feeling being. In the inexhaustible controversy over nature vs. nurture, genetics vs. the environment, one crucial point in our development has been unanimously overlooked. It's the moment of maximum plasticity; it's the time when everything that happens to us has the power to shape us that surpasses the joint efforts of nature and nurture at any later time. We've all been there. We had no choice but to feel -- we existed as raw feelings, we had nothing as yet to reason with. And whatever it was that we felt -- remember we felt 70% of it through the eyes. We are the direct outcome of the kind of visual stimulation we received back then, of the lessons our eyes were taught by light and darkness and smiles and frowns. What were they taught? Was it what they really needed to learn? For instance, consider this: they were told "bright light!!!" the moment you were born. How did they respond? How do they respond today if you're suddenly assaulted with bright light in the middle of the night? And how do you think they would respond if suddenly assaulted with bright light not after a few hours, but after nine months of total darkness? Why does every animal whose young are born relatively helpless (though not many are born as helpless and dependent as human babies, and none remain so for as long) hide in a dark place in order to give birth? How do you respond to a sudden painful burn? A burn to your eyes and your brain? How would a hand, a paw, an antenna, a tentacle respond? What are your options if it's going on and on and on? In what direction will any organ equipped with muscles move if presented with an adverse stimulus? (Answer: AWAY. As in, posterior elongation...) How does an overload of adverse stimuli affect neural transmission? (Answer: CAUSES EXHAUSTION AND SHUTDOWN OF TRANSMISSION. As in, suppression of impulses from the site of the most acute overstimulation, the fovea centralis...) How do you move your movable bodily parts when you're assaulted and are trying to escape, and finding no escape anywhere? (Answer: CHAOTICALLY. As in, loss of smooth saccadic movements...) What happens to any organ retained in a certain stressful position by a muscle spasm? (Answer: IT SWELLS UP, because free circulation of fluids is blocked...) What's the difference between a specific and a non-specific stress response? (Tip: what's the difference between low and high myopia?) Is a learned defense mechanism a "disease" or a "variant of the norm" or

neither?.. How do you switch off an obsolete stress response that your system has prototypically registered as SUCCESSFUL and recognizes/remembers as such on a fundamental biophysiological level? Is it any wonder it will try to use it again whenever challenged with stress or trauma -- and defend it like there's no tomorrow? What else is there to do but establish a precise connection to its source so that you're finally conscious of what it is that you're doing with your eyes and your mind, and most importantly, WHY?.. How else can you stop doing it?

Feel it. When I started getting my specific personal answers as feelings, some of them eventually started making a lot of "general," "objective" sense too... unless I'm mistaken when I think that we all belong to the same species... in which case whatever I experience as feelings will certainly make no sense to anyone else.

Try using a pillow. Another thought from the laying on of hands perspective. This is a very ancient healing practice found in cultures world wide. The palms are supposed to have chakra points that emit healing energy. If someone was really sick, a group of people would come to the sickbed and lay their hands on that person. I'm getting a sense from reading this stuff that the human energy field works somewhat like computers and the internet. You can transfer files from one person to another in a sense. Through the energy, the prana. My point is, get a good friend, with good eye sight, to sit behind you, lots of pillows and let him or her palm you. I know of no research on this and I can't be held responsible for the results or lack thereof .

Robert

That's good news. Firstly, you can test your own improvement without having to wait for an optometrist visit and secondly, earlier evidence of improvement can only help the positive thinking side of things.

Can I ask you another question? I'd like to have my eyechart up at work so that I can test my eyes during the day (ie not at home when I am tired). The trouble is, to have it fairly discretely displayed, I can't get more than 6 to 10 feet away from it. So... would you expect the ability to see small letters from a closer distance improve in line with the ability to see larger letters from further away - or are the two things quite separate?

(In the meantime I'm using a building in the distance as a rough measure and trying to count the number of aerials on it. I started with 8 but can now see 9 - and 14 if I blink.)

Thanks  
Caroline

I said after Caroline inquired:

It doesn't matter where you put the eye chart. The smaller letters will look clearer when the chart is closer. This is okay. I like your experiment with the aerals. I have done a similar thing. I love the verticality for my astigmatism.

If you have access to a laser printer, you can make your own eye charts very simply. Get the files (or instructions on making your own custom eye chart) at...

[http://ezinfo.ucs.indiana.edu/~aeulenbe/i\\_see/eyecharts.html](http://ezinfo.ucs.indiana.edu/~aeulenbe/i_see/eyecharts.html)

Included are standard Snellen charts and an "astigmatic mirror" chart designed for monitoring (and controlling) astigmatism.

>Anyone knows where can I get a cheap eyechart (I need to start baseline  
>measurements)

Is FREE close enough? I took the Snellen eyechart off the I-SEE web page and redrew it as an .eps document (the PICT file was too lo-res, the lower lines came out very blurry). This .eps will print out perfectly on a postscript laser printer, or from Illustrator/ATM to a regular printer.

I would like to offer it to the I-SEE webmaster to make it available to everyone. (are you here?) I could also convert it to a higher res if someone needs it and doesnt have the postscript equipment, the file would be pretty large at 300dpi though.

> larger letters from further away - or are the two things quite separate?

Since you're nearsighted, yes they are separate -- your visual acuity close up will be better than your visual acuity at distance. If you can get the eye chart 10 feet away, that's about 3 meters, there is about 1/6 of a diopter difference between that and having an eye chart 6 meters away, which is probably not noticeable. So yes if you could get an eye chart scaled down by a factor of 2 you could put it 10 feet away from you.

Or, you could buy 1 D reading glasses and look at the eye chart through them. You would put the eye chart 1 meter away since that's an optical distance of infinity when you're wearing 1 D reading glasses. You would need to get an eye chart with the size of the letters scaled down -- if it's normally at 6 meters you would get or make an eye chart with letters 1/6 th the size. However the drug store reading glasses don't have great optics -- if you are interested in the fine points of vision that may not work.

Does your eye chart have 20/20, 20/15 and 20/10 lines? Is it designed to be looked at 20 feet away? Is it the Snellen eye chart or some other layout of letters?

Thanks.

> 17/08/96                   -2.25    -2.75

I get the impression this happens with a lot of people. They get 1 D or so improvement with exercises & plus lenses but it stops there. It sounds like people can stretch their ciliary muscles a bit but it might be hard beyond a certain point.

> Lately I have started thinking about my next step in improving my vision and

How about LASIK? Some people seem to believe that's the next wave in terms of surgery.

About OK -- you might want to look in Deja News for back postings on that

in sci.med.vision. Deja News is at <http://www.dejanews.com>. Richard Adams tried OK and posted in sci.med.vision reviews of his experience a couple of times. It didn't work for him.

> I have read all the stuff that people have posted about PRK and by the way

> hasn't been!!!  
> 2- the cost. In Australia, it costs between A\$1,750-A\$2,250 per eye. That's a  
> LOT.

Maybe it's cheaper someplace else? You might want to look into other countries. It might be worth it to fly someplace to get it. I've heard that Columbia is the place that pioneered LASIK, they do a lot of it and are good at it now.

It wasn't clear if you're doing vision therapy with your optometrist or if they're just measuring you. You might want to seek out someone who works on myopia reduction.

I wonder though, whether trying to reduce myopia by plus lenses, etc. can be harmful after a point. I wonder whether there have been studies on how this affects the eye's functioning, if there may be any consequences. If one does just have long eyeballs, if one were born with them, trying to work on the ciliary muscle to compensate for that nearsightedness might possibly have negative effects, if one were training the ciliary muscle to do things it doesn't naturally do.

Hello George,

I have many patients whose prescription in dioptric values are larger than yours  
and who are legal to drive without their glasses ( ie their naked eyesight  
is 6/12, which is the metric equivalent of 20/40 ). Your progress relates

to your ability to be clear without your spectacles - not the numbers. Let go of your attachment to the value of the prescription.

You have the ability to BE clear in spite of your spectacle prescription. That is you have the ability in every moment to be fully present. Through this awareness you will reverse the visual contraction.

Yours in health and light,

Peter

Its benefits? And the strange experiential obstacles we encounter (mentioned by several people) -- it takes only a few minutes to realize that this seemingly simple exercise is in fact difficult to perform no matter how we go about it? Check out if the following explanation makes sense in conjunction with my today's Feel It post:

Palming works simply because at some point in our development, we were starved for darkness. It works because it satisfies a basic natural need -- namely, the need to have spent enough time in the dark to prevent overstimulation of the visual system which was still immature and fragile.

Palming is difficult to perform because our feeling mind is reminded of what it was that we needed and were denied. Excluding all light and starting to look quietly into complete darkness makes us nervous because it's exactly what retrieves the traumatic unconscious memory of what we longed for. What is difficult to handle is in fact a sensory memory of the way one of our natural basic needs was denied fulfillment.

I think not so much palming as exposure to LOTS of total darkness (while staying awake!) may be curative for some, although probably difficult to handle emotionally for most. I plan to experiment and will report on the results. I will have to have a few hours to spare (whenever....) and to light-proof a room (wouldn't want to get into a closet -- don't really feel like swapping myopia for claustrophobia...)

I saw some questions about the Vision Freedom product. Someone I talked to on the phone from CA gave me Brian's phone number. I called and got the sales literature. What caught my attention in the sales literature, was all you had to do was wear these glasses 2 hours a day. What he doesn't say is you have to continually adjust your focusing distance during those 2 hours. We have a local vision improvement network here in Orlando area who meet once a month. I showed the others the literature. One of the members had ordered the Vision Freedom kit and brought it with her. She did not have much luck with it. She couldn't understand what it was she was supposed to do. I looked it over since I was interested and have already studied and pursued ideas from Bates, Goodrich, Lieberman, Kaplan, Cambridge, Berne, and probably more. I didn't feel like it was anything different than what I already knew. It is basically practicing focusing at different distances with different plus lenses.

Has anyone actually totally thrown away their glasses using his kit and method? Of course, they probably are not on this list anymore as their vision would no longer be an issue for them.

In addition, I totally believe vision is emotional based. If you can clear why you distorted and/or blurred your vision, the brain will have the eyeball change to conform to your new awareness and belief systems. I personally have been improving my vision for the past 1 1/2 years using a combination of things. I have studied and used methods mentioned above, plus experienced much personal growth and emotional release work. I have eliminated all astigmatism (distortion) except for -.5 in right eye. The rest of the

prescription is less than half of what it was before I started. It has been taking a long time and if I think about it I can feel frustrated.

Who are all these people in the books that see 20/20 in just a shift of awareness in a week's time?

I have been working with Dr. Mancini from NH who comes down here periodically. Energetically we have determined that I will no longer need any compensating prescription sometime between Aug this year and Aug next year. I do not know how long it will take my physical eyeball to match the energetics. I guess that is where the exercises/games would help.

That is it for now ... I am just new to this list.

In the UK, I've noticed at a few motorway service stations selling 'reading glasses' from a vending machine.

They come in low, medium and strong prescription.

Has anyone heard of a similar way of getting distance glasses, I'm interested in getting some plus glasses and this may be an easy and inexpensive way of trying them.

I've been using pin-hole glasses for about 1/2 hour a day - anyone had any experience of these?

Also, the imperfections on your eye that look like bacteria on a microscope - would you see them when looking at distant objects or close up?

Thanks all

Mark

This notion of an over-bright birth and myopia is very interesting. It seems quite logical. How do you explain the time lapse between birth and actual development of myopia? What types of factors are capable of causing the present-day response in the eyes(the shrinking back) are these isolated events, or some sort of metaphorical continuous bright light? Why would the shrinking away of the eye be a strategy in *\*any\** stressful situation?

I don't know why palming is uncomfortable for some folks, but Elena's post got me thinking about why it is so effective.

Could it be that we are suffering from a lack of waking darkness? Ordinarily, without artificial lighting, we would spend a good bit of time each day awake - but in darkness. Until the recent past, that is the way things were. Our bodies could be missing this exposure to darkness (and our eyes are the primary way we are aware of this).

Just as our bodies are unable to produce enough vitamin D when we go about covered in clothing and spend most of our time under artificial light - we may be depriving ourselves of some other crucial element by spending all our waking hours in the light.

Hello I\_seer's

I have a few question. Firstly I'm quite new to this list.  
I got a new prescription of:

O.D. -6.75-1.00\*10  
O.S. -7.50-0.50\*145

I know i have a quite strong prescription for my age, but don't believe it is genetic. My parents never got or needed glasses until they came to Canada.

My current prescription i'm wearing is -5.50 both eyes, also it is almost 4 years old. I'm going to grade nine this year and need to be able to see the blackboard. I'm afraid this prescription is too high even though this eye doctor is said to be one of the best in the city.

I don't know of any Eye doctors in my area who would prescibe 20/40 for me.I was thinking of getting +lenses from the drugstore. Although i'm not quite sure what strength to get. Could anybody give me a few suggestion on what + lense strength would be best, what would a 20/40 prescription be according to the new prescription i got, as well as techniques or exercises or activities other higher myopes have tried and worked ?

Could someone please explain to me what the second and third numbers represent for my prescription? I'm not familiar with those.

Thanks in advance,

Peter

>Anyone knows where can I get a cheap eyechart (I need to start baseline  
>measurements)

You can buy an eye chart from Edmund Scientific ([www.edsci.com](http://www.edsci.com)) for around \$10 or so. I bought one of theirs long ago. You might also be interested in their "Self-Screening Vision Tester" which is a cute little device with a (cheap plastic) plus lens and a very tiny snellen chart that you slide back and forth. You find the distance at which you can see the 20/20 line and you read your diopters of nearsightedness right off the scale. You can also measure the near point too (and need for plus lenses). I've enjoyed playing with it, but I'd really rather have a more repeatable measurement of refractive error. It's under \$20.

Edmund Scientific contact info (from <http://www.edsci.com/directory.html>):  
Customer Service- For order status, no technical customer assistance  
Telephone: 609-573-6260  
Fax: 609-573-6295  
E-Mail: [service@edsci.com](mailto:service@edsci.com)

Product Information - Technical product assistance and specifications  
Telephone: 609-513-6259  
Fax: 609-573-6233  
E-Mail: [techsup@edsci.com](mailto:techsup@edsci.com)

It appears that the Edmund eye chart comes from Medi-Source

at Medi-Source Inc...50 Gordon Dr...Syosset, NY 11791-4719  
Phone: (516)496-3700

The little vision tester apparently came from "Frank Custom Plastics"  
at 904-788-4251, Daytona Beach, Fl. (Perhaps custom mfgd for Edmund.)

You can make your own eye chart from the information at  
[http://ezinfo.ucs.indiana.edu/~aeulenbe/i\\_see/eyecharts.html](http://ezinfo.ucs.indiana.edu/~aeulenbe/i_see/eyecharts.html)  
where you'll also find some "ready made" charts. I made  
one in Microsoft Word (going from 10 feet to 70 feet)  
based on the point sizes I found there and I use it all  
the time.

You can buy William H. Bates' "Better Eyesight Without Glasses"  
for \$8.95 at Barnes and Noble, or for \$8.05 (plus shipping)  
at <http://www.amazon.com/exec/obidos/ats-query/0674-3219602-412801>  
(Shipping is \$3/order plus \$0.95/book, I believe.)

Dr. Kaplan's "Seeing Without Glasses" (\$12.95) has a couple of  
smaller size eye charts (9 x 6 inches or so).

You can get a professional "baseline measurement" at any  
optometrist in a mall, often on a walk-in basis, for \$40-50.  
Of course, they don't call it that... it'll help your  
credibility!

I think a 20/40 prescription would have about 3/4 of a diopter less minus  
in the first column, assuming your prescription was for 20/20 vision. The  
first column, -6.75 and -7.5 is your spherical correction. I'm not too  
sure about the 3/4 of a diopter less.

You could try calling your eye doctor and asking them if they would add  
the proper amount of plus to make it a 20/40 prescription. They might

call in a new prescription over the phone to the place you're getting your glasses from.

Or try calling eye doctors and asking them if they'll write you a 20/40 undercorrection, before you see them. Or ask Paul Harris babo@ix.netcom.com for a referral to a behavioral optometrist, who are likely to prescribe undercorrections, near vision glasses, etc.

For reading glasses -- you can get a near prescription with less minus as a second pair of glasses. Or you can wear drugstore reading glasses over your regular glasses. If you get them from a drugstore, hold a book at your usual reading distance from your eyes, 15 inches or so, with your regular glasses on. Then try on reading glasses over them -- buy the strength so that the print in the book is just a little fuzzy. This should be the "fitness" strength.

Those are astigmatism. You have slight astigmatism, in your right eye -1 D at an axis of 10 degrees and in your left eye -0.50 D at an axis of 145 degrees.

The time lapse between the moment when the body and the mind are forced to learn a drastic defense pattern (aimed at coping with a traumatic experience, and always THE BEST ONE AVAILABLE under the circumstances), and the moment when its actual existence becomes explicit, is considerable in many conditions -- it's the "norm" for chronic ailments rather than an exception. In fact, there are no exceptions at all, just chronological inadequacies of diagnostics -- we (or our doctor) notice a "disease" when a certain limited number of symptoms (or whatever diagnostics methods are available) finally LET US us notice it, not when it actually starts to form. For instance, one will have elevated stomach acidity years before developing ulcers; high cholesterol years before any explicit coronary insufficiencies, and decades before suffering a heart attack; emotional coldness, lack of empathy, and a sense of detachment years or decades before descending into schizophrenia; abnormal deposits in the joints decades before the onset of arthritis... and so on. A prototypical stress response is learned early, stored as a pattern of defense (aka an unconscious memory), and subsequently activated whenever normal functioning is disrupted by a new overload. The latter may be either sudden (in which case they will talk of a "psychosomatic" disease or a PTSD), or just a gradual build-up above the capacity for coping.

Bright light may be only one (albeit significant, judging from what I was

able to disentangle) component to go into the equation "traumatic visual experience = defensive visual response." Any number of other traumatic experiences may have similar vision-related effects. To a one-year-old, seeing an angry or threatening look in a parent's face, or chronic lack of interest and approval, is as traumatic and painful and beyond comprehension as a burn to her eyes. She will respond by trying to minimize awareness of what she sees -- its unbearable MEANING. She won't necessarily become myopic to achieve this end -- she may just become stupid instead, unaware, disconnected... someone who "doesn't get it." Well she can't afford to "get it," it's too painful! If the parents approve of intellectual achievements and are very critical of "stupidity," the child might become very smart in order to avoid disapproval, and then the best outlet available for reducing awareness will be to become myopic. If they approve of physical fitness and don't care for the brainy stuff she might become athletic to please them and utilise the outlet of dyslexia rather than myopia in order to "not get it." Whatever it is that they want, a very small child will try to oblige because survival rides on it, she's too helpless yet to afford alienating her parents by non-compliance. We are programmed to fine-tune our development to our parents' needs (and the society's needs that copy them), while our own get "satisfied" by our bodies and minds going awry, going out of their way in order to adapt to the impossible -- to the cancellation of our natural basic human needs.

The severity of trauma has everything to do with the time of occurrence. The earliest is effectively worse than the most terrible that occurs later. Judging from the information I've gathered on the survey so far, being born to an overmedicated mother (which means having the drug of repression in the system during the stress of birth and therefore having biochemically learned repression of vital functions as a prototypical response to stress), or being born premature (and therefore supersensitive to stimuli that might have caused only mild distress in a mature baby), correlates with moderate/high myopia to a greater extent than a drinking father, a violent family, and even sexual abuse. However, the double jeopardy of adverse birth circumstances PLUS traumatic family circumstances yields moderate to extremely high myopia not in 99% (as in my preliminary estimate) but in 100% of such cases.

A non-specific stress response is an early pattern that gets established when the mechanism for differentiating stimuli is not yet developed properly. In other words, a neonatal may respond with stomach cramps or respiratory distress to ANY type of stress, not necessarily gastric or respiratory. Similarly, visual stress that is very early and very traumatic will be registered first of all as STRESS, and its meaning of specifically VISUAL stress will be registered as secondary. In low myopia, however, we seem to be dealing with a SPECIFIC response to specifically VISUAL stress. It doesn't correlate with any early traumatic experiences other than the bright lighting of the delivery room -- which however seems to be a universal factor. Of the cases I've reviewed, only two were births in dim

light, and of those, one was not a myopia case but presbyopia (with very bad childhood experiences); the other one -- a home birth with a midwife, ordinary bedroom lighting -- was a case of very low myopia.

No correlation with the amount of near-point work was found. Wearing glasses full-time, or wearing them for near-point work as well as for the distance, seems to correlate with greater progression rates in all types of myopia, but this I haven't yet analyzed thoroughly so the data is preliminary.

I believe there may be a connection here. Even though coal miners work with artificial light deep underground, much of their job is spent in semi-darkness. They must have a higher degree of night vision in order to

remain productive in such an environment. You could probably add to that amateur (or even professional) optical astronomers who sit in vast darkness to snatch a look at their prey!

Hmmm... What about babies that are born under different circumstances??  
E.g. Low level lighting in the delivery room, higher room temps during  
birth, underwater birth, etc.

Any idea if these babies have developed myopia to match the statistics  
for  
us "high lighting" births?

Hi

Can anyone help with an astigmatism question?

Does the fact that my astigmatism wheel seem to have clearer horizontal than vertical lines on a print, but clearer vertical than horizontal lines on my computer screen mean anything?.

I know what the difference in clarify between horizontal and vertical means, but I was surprised that it was the 'wrong way round' on the screen compared with the print.

Caroline

I know it's not easy for anyone else to interpret dream meanings, (since it is normally the feeling that goes with the dream that counts, rather than the actual contents of the dream), but I've had a couple of dreams about eyes and I wonder if anyone (Elena?) could help with what I am supposed to learn from these.

1. Until recently I used to have a recurrent dream wherein I couldn't open my eyes because the light was too bright. It brought a feeling of panic as I tried to work/go about my daily life whilst peering through tiny slits in my eyelids. It felt like when you have poked your eye and it waters when you try to open it, but it didn't get any better during the dream.

I would awake with a feeling of great unease. Usually the sun would be shining into my room so I put it down to the lack of curtains, but I wonder if it shows something about my reaction to light since I also find sunning uncomfortable.

(I haven't worn sunglasses for about a year now and I try to sun for a minute or two each day).

Since I have moved house (June) I have had a less sunny bedroom and haven't had the dream.

2. Last week I dreamt that I had no sight in my left eye temporarily. I was looking at something and realised that the left half of my visual field was missing. I felt a panicky sensation. Eventually the sight came back. I woke up to a feeling of unease.

Does everyone who is worried about eyesight and thinks a lot about it each day dream like this or is there something more here that I need to investigate?

Many thanks for any ideas,  
Caroline

Caroline, I don't know what to make of these dreams and I will defer to a more knowledgeable authority (Elena?). However, my 2 cents were burning a hole in my pocket so here goes.

I had a recurring dream about not being able to open my eyes fully. Actually, in the dream my eyes were barely able to open at all! All of the images in the dream were very dim and full of washed out colors. Very difficult when trying to lead a normal daily life!

This dream used to come and go many times over the years but I haven't had

it recently (over the past 2 or 3 years). I haven't even thought about it until I saw your post. Now that I think about it, it was most likely during a time in my life when my myopia was steadily getting worse and my tolerance for glasses was getting very, very thin.

Hmmmm... Since I have taken a proactive role in my vision quest, that dream has not returned.

Any connections here?? Hmmmm????

Dear Peter,

thanks for your note regarding my progress.

First let me say that I'm extremely happy with my progress so far:

- a) I got rid of 1 diopter in each eye
- b) I do not need sunglasses anymore
- c) my eyes feel a LOT healthier

Currently I have 2 issues:

1- I'm having difficulties grasping the idea of vision vs. visual acuity. I have read so many posts on this but I still cannot differentiate between the two. You said:

"I have many patients whose prescription in dioptric values are larger than yours and who are legal to drive without their glasses ( ie their naked eyesight is 6/12, which is the metric equivalent of 20/40 )."

Could you explain how you could measure their eyesight to 20/40?

2- So far no one has been able to tell me why I see double images of VERTICAL objects. A symptom that goes away when I put my glasses on.

The optometrist could not figure out why since I only have minor astigmatism in my left eye and my glasses don't have any correction for that. When I asked him if this is how myops would see things he said no. It may sound weird but I'm beginning to think that I do not have myopia!!

Here's what it's like: let's say I'm looking at a sign on the street containing the word MARKET. the way I would see it looks like 2 images one on top the other but slightly shifted horizontaly. So It's like looking at IMIAIRIKIEIT. So you see all the vertical lines appear twice making the whole image really fuzzy.

If I focus hard on ONE of them trying to mentally eliminate the other, it appears to be quite clear. In other words, if the shadow image is not there, everything would be very clear.

This is not the normal kind of fuziness where you cannot detect the sharp edges of the letters. It's double images.

My theory is that my eyeballs have been flattened by vertical (up and down) pressure by the muscles creating 2 virtual focal points in each eye.

How can I fix this? I have no idea. But I know it has to be in exercising the muscles and to tell my brain to ignore one the images. Simple don't you think???)

Any ideas that you may have would be greatly appreciated.

regards

george

Hello George,

I have many patients whose prescription in dioptric values are larger than yours and who are legal to drive without their glasses ( ie their naked eyesight is 6/12, which is the metric equivalent of 20/40 ). Your progress relates to your ability to be clear without your spectacles - not the numbers. Let go of your attachment to the value of the prescription.

You have the ability to BE clear in spite of your spectacle prescription. That is you have the ability in every moment to be fully present. Through this awareness you will reverse the visual contraction.

Yours in health and light,

Peter

No information. I think dim lighting at birth must be a great head-start for subsequent visual health. The countries that don't have the shiny "advanced" obstetrics don't run nearly as high rates of myopia. Of course by way of evidence this is very indirect. Sorry I can't do better here -- not a single Trobriand islander e-mailed me from the dark cave he was born in with explanations of how come he's NOT myopic, so I wouldn't know :-).

The general assumption is, not all birth is traumatic or abusive but a traumatic or abusive birth is. Bright lighting at birth amounts to harsh abuse of the visual system. Ultrasonic observations show that a five-month-old fetus in the womb will promptly turn its face away from a bright light directed at the mother's abdomen. The sensitivity of the retina at birth is five times higher than in adulthood.

I'm sure that simple physical strain is a large component of the problem. If you have any residual tension in the muscles of the shoulder's and the neck its bound to hamper relaxation - the brain is getting a constant flow of demands to do something about the discomfort. I've had some improvement by palming whilst lying down in the Alexander fashion (i.e. on back, knees raised so that calves, floor and thighs form an equilateral triangle). The elbow is then directly above the shoulder and this seems to need less muscular tension to sustain.

You can also achieve some degree of darkness by getting a pair of safety goggles and painting with black paint. I found this worked quite well, but suspect that the warmth of the hands in "proper" palming has some relaxing effect on the eyes.

It would be nice to hear from anyone who finds palming effective and what strategy they use.

Peter

Peter, for a 9th grader, you have been diagnosed with an extremely high amount of myopia. I would strongly suggest a second opinion. Since you are young, you have an excellent chance of losing many diopters in a short time, and eventually being able to go without glasses comfortably. I know of two adults who have brought their prescription down by four or more diopters over a matter of years. YOU CAN DO IT TOO. The most important point is to SIMPLY NOT WEAR GLASSES, or WEAR THE WEAKEST LENSES YOU CAN TOLERATE. The second most important point is to get a prescription without cylinders (astigmatism correction).

You don't need to drive.

You don't even need to look at the blackboard because you don't have to go to school! In the U.S. and Canada it is not required by law to go to school (much less stare at the blackboard). A good page on the subject is...

<http://www.cis.upenn.edu/~brada/homeschooling.html>

I seem to notice a pattern of Canadians rapidly becoming myopic. I noticed this by following the sci.med.vision newsgroup. My guess is it has to do with light deprivation. That's also why I think it would be a great idea to NOT GO TO SCHOOL. A community of Eskimos in Barrow, Alaska, had mostly farsighted vision until mass schooling was instituted. Up in those Arctic latitudes during the winter months, your eyes need all the light they can get. Sunlight is essential in producing vitamin D, which you need in order to absorb calcium. Without calcium, the tissues in your eyes are weakened. (At least that's my theory of what happens.)

>

> to see the blackboard.

No you don't!

> I'm afraid this prescription is too high even  
> though this eye doctor is said to be one of the best in the city.

Your OLD prescription is probably too high (never mind your new one) -- as you will find after a month or so of training.

You may even be able to prove this to yourself in a few minutes that you have not been using your eyes to their full capacity with those glasses on.

First, get yourself an eye chart (see the I SEE page < [http://ezinfo.ucs.indiana.edu/~aeulenbe/i\\_see](http://ezinfo.ucs.indiana.edu/~aeulenbe/i_see) > for files and instructions on making your own) and measure your vision at 20 feet with your glasses on.

Then, (THIS IS IMPORTANT) take your glasses off and read something. If you get double vision, cover one eye. Don't worry that you have to hold the page close to your face. But do keep pushing the page of text back, as it becomes clearer in your vision. Make sure you do this for each eye. After several minutes of this, and it looks like you can't make yourself see any farther, put your glasses on again and measure your vision with the chart.

You actually don't need a chart to try this, if you can remember some distant landmarks and exactly how clear they were before you did the exercise.

>

> I don't know of any Eye doctors in my area who would prescribe 20/40  
> for me.

Well, I bet you're already seeing 20/40 or worse with your -5.50's since

the "best doctor in the city" has just prescribed you about a diopter and a half more than what you already are wearing.

> I was thinking of getting +lenses from the drugstore. Although i'm not  
> quite sure what strength to get. Could anybody give me a few suggestion  
> on what + lense strength would be best, what would a 20/40 prescription be  
> according to the new prescription i got, as well as techniques or exercises or  
> activities other higher myopes have tried and worked ?

You do not need plus lenses -- yet. Plus lenses are for myopes who are comfortable without their minus glasses and need an extra challenge.

However, eventually, after you have retrained your eyes, you will want some lower power lenses. You can go to any optometrist for this.

Robert-Michael Kaplan <beyond\_20/20@sunshine.net>, who resides in British Columbia, is familiar with the Canadian scene and should be able to recommend a sympathetic optometrist.

>  
> Could someone please explain to me what the second and third numbers  
> represent for my prescription? I'm not familiar with those.  
>

As Nick said, those are for astigmatism. That's icing on the cake whose only purpose is to make people think that prescribing glasses is some kind of sophisticated exact science. I'll have more to say on this when replying to George Tohme, whose astigmatism vanishes when using a purely spherical glass.

I have it on many sources that astigmatism under 1 diopter is not worth correcting. Please see at the I SEE library, the article "Changes in Corneal Astigmatism" by optometrist C.W. Parker

[http://ezinfo.ucs.indiana.edu/~aeulenbe/i\\_see/parker.html](http://ezinfo.ucs.indiana.edu/~aeulenbe/i_see/parker.html)

Caroline:

Once in a while, maybe a couple of times per year, I sometimes dream that I can't open my eyes to see properly. This is usually when I feel a great need to see (e.g. someone is trying to bust through the door and I'm trying to see the lock). I think it's the fear that is the hinderance. I was playing a simple saxophone solo in my band this week and I messed it up, simply because I was nervous and afraid of messing it up, so I did! Someone on the list mentioned that he had the "intent" to see properly and he eventually saw more clearly. I would add that with this intent, we need to overcome the fear of not being able to see clearly.

Tim

# What model should we use for myopia?

---

- *To:* [i\\_see@indiana.edu](mailto:i_see@indiana.edu)
  - *Subject:* What model should we use for myopia?
  - *From:* [P.Croyden@sussex.ac.uk](mailto:P.Croyden@sussex.ac.uk) (Peter Croyden)
  - *Date:* Fri, 23 Aug 1996 16:30:09 +0100 (BST)
  - *Sender:* [owner-i\\_see@indiana.edu](mailto:owner-i_see@indiana.edu)
- 

What follows is pretty muddled and ill-thought out. There are two people to blame for this.

- 1) Me.
- 2) Elena, for saying in one of her recent posts "don't hide in you inner space, its not good for you eyes" This spurred me into posting rather than lurking. :-)

My reason for posting is to try and construct a model for myopia that will help me improve my own poor eyesight. I'm full of admiration for Elena and her progress, but I don't feel that her model fits my circumstances. I had heard of Janov through a relative whose life had been changed by his ideas, so I got a couple of his books from the library, but they did not inspire me. Maybe I'm hiding my feelings too well, but my recent experiences with the Alexander Principle make me think that my solution lies down that path. This from someone who has been trying Visual Therapy for 10 months and still has a worst case acuity that hasn't changed.

I have three reasons for thinking that most myopia is caused by simply wrong mental habits and not by emotional trauma.

- 1) Bates doesn't mention it.
- 2) Whenever I experience flashes of better sight, it is not accompanied by overwhelming feelings, but just feels good.
- 3) My exposure to the Alexander Principle has shown me how deeply ingrained bad habits can be, but how they can be changed by

thinking in the correct way. I suddenly developed debilitating neck pain about two years ago, which I alleviated by doing the MaKenzie excercises, but only cured by having Alexander lessons (If you're interested there is a good book by Wilfred Barlow - The Alexander Principle, published by Gollanz Paperback 1990) My reason for mentioning this is that I met someone who claims to have gone from -6D to 20/20 by applying Bates. He thinks there is a strong affinity between the two, they both involve not doing the wrong thing, rather than doing the right one and not trying too hard.

What do you think?

The myopic me says "Where am I going wrong?"

Peter

Peter,

I do agree, your prescription is quite high at this stage of your life. But I also understand that you may WANT to (although you don't HAVE to do anything in your life except to die - as the stoic said) get a good education, drive a car and do all kind of stuff, requiring good vision.

Allow me to be the "proof in the pudding".

I am 52 years old, have gone during my life through a lot of stressful situations (some of them still ongoing). At the age of 49 - following one of the very stressful episodes - I began going blind. Measured -18.0 on my right eye and a bit less on my less eye (and counting) I departed on my journey towards seeing again. The details of this story are long and surely not interesting at this point. Although maintaining my responsibilities in life I was able through inspirations of such as Adouls Huxley (The Art of Seeing), Dr. Bates, Dr. Robert-Michael Kaplan and others (my Calgary behavioral optometrist, who keeps my prescription reduced and cheers on when I make a progress) reverse my myopia to the point of approximately -12.0 to -11.0 O.D. - depending on how I FEEL the particular day, week or month.

I have learned NOT TO BE AFRAID OF NOT SEEING. I have learned of being able to drive with my 20/75 prescription when the sun shines. When cloudy or in need to see 20/20 (business meetings, reading signs

on the doors, etc.) I have a -1.25 dioptres plus a bit of astigmatism adjustment glasses, that I put on over my contact lenses and then take them off when not needed. (That is the time when I devour in feeling and listening, before my reduced vision kicks in). By continually maintaining weaker prescription and daily morning exercises plus eye charts and other tools hanging everywhere I go for constant reminder to my brain that I ought to use my eyes differently then what I used to for 49 years, my eyes are getting better. The first progress was very fast - now it is slow - at times in a bit reversal mode - again depending on MY demands on my mind and my feelings - hence my eyes.

You certainly have a great chance - if you WANT to succeed. It is a personality moulding process, not an easy journey - but it is "travellable" and rewarding!

I hope, this gives you a bit of inspiration as well. Good Luck.  
Katerina

My husband and I are myopes in the -5 to -6 range. Our daughters were both tested as mildly hypermetropic - the one who was born at home the more so.

I am hoping that by freeing them from the classroom and allowing them to develop at their own pace their vision will be preserved. In any event, they won't be forced to wear minus lenses that (we believe) cause progressive myopic deterioration.

I have that as well George, when i'm not wearing my glasses, occasionly I can see the horizontal perfectly at a very far distance and then suddenly after i blink it's gone. I get this quite often aswell, while walking my dog outside without my glasses. I thought it was astigmatism. But now i'm

beginning to think it's something else.

Is this more noticeable at night? It is possible that the outer part of your cornea has a different curvature from the inner part which could produce double images.

> The most important point is to SIMPLY NOT WEAR GLASSES, or WEAR THE  
> WEAKEST LENSES YOU CAN TOLERATE. The second most important point is to  
> get a prescription without cylinders (astigmatism correction).

Why would not wearing glasses at all be better than getting a 20/40 undercorrection? Is there evidence that not wearing glasses at all is better for vision improvement than using an undercorrection? An undercorrection might actually work better for vision improvement, because one's eyes might adjust their focus better if there's a slight blur -- if one's vision is very blurred the eyes may just give up on trying to focus, but if there's a slight blur focus may be possible by relaxing the eye.

The other thing about not wearing glasses at all is that if one's eyes are quite different in visual acuity, the worse eye may become lazy. And going around with quite blurry vision, seems likely to cause eyestrain.

Also, why leave cylinders out? I've read around and haven't heard any reasons for that except that cylinders "distort vision". Any prescription of course distorts vision. I've seen some things on why using an astigmatism correction, even a small one, is good -- there was one study I saw which compared eyestrain in computer terminal users between people who had small amounts of astigmatism but used no astigmatism correction, and people whose small amounts of astigmatism was corrected.

There was less eyestrain for the people whose astigmatism was corrected. I think that astigmatism causes eyestrain because the image is never quite in focus. Horizontal lines may be in focus, and vertical lines may be in focus, but not at the same time. And I read, though I don't remember whether this was just a theory or not, that with slight astigmatism, one shifts focus back and forth to focus vertical and horizontal lines and to try to assemble a good image from this varying focus. Changing focus like that is tiring, which causes eyestrain.

Also, if one has a lot of astigmatism and doesn't get it corrected, one's eyes are quite likely to lose the ability to be corrected to 20/20, though they may get this ability back after wearing vision correction for a while. I'm not quite sure if this is because one's eyes lose the ability to maintain a constant focus with astigmatism, or if one's brain becomes "lazy" about processing images from the retina of an astigmatic eye, or both. Astigmatism means that the retina never, at any distance, receives an entirely sharp image, and one's brain may get "lazy" about processing images that are always blurred.

This applies more to large amounts of astigmatism, not small amounts like 0.5 D or 1.0 D. But still, astigmatism is a strain on the visual system.

I suppose that one's astigmatism might change if they're working on reducing myopia, but that isn't an argument for not using an astigmatism correction. I haven't seen evidence on cylinder corrections actually causing more astigmatism -- I'd wonder about that for very young children but I doubt it for anyone older.

> I have it on many sources that astigmatism under 1 diopter is not worth  
> correcting. Please see at the I SEE library, the article "Changes in  
> Corneal Astigmatism" by optometrist C.W. Parker  
>  
> [http://ezinfo.ucs.indiana.edu/~aeulenbe/i\\_see/parker.html](http://ezinfo.ucs.indiana.edu/~aeulenbe/i_see/parker.html)

This article, from 1931, mentions one case of varying astigmatism that he himself calls a "freak case" and says something about another case where he said someone accepted lower astigmatism correction. But, one case and one article isn't much to hinge opinions on. Even behavioral optometrists seem to avoid claims about being able to fix astigmatism, although some of them \*do\* work on myopia reduction.

>1) Bates doesn't mention it.

Oh yes he does -- all over the place! A health-related genius that he was, how could he have missed it? He hardly mentions anything else!

Bates calls it "mental strain." Janov calls it "Primal Pain." Bates intuited its existence and gave it a generic name. Janov discovered its existence and gave it a brand name.

>2) Whenever I experience flashes of better sight, it is not  
>accompanied by overwhelming feelings, but just feels good.

Doesn't surprise me Peter. You haven't dealt with dramatic changes in your vision yet. Some of my old posts might testify to my fairly frequently expressed happy-happy-joy-joy, go-get-it attitude of several months ago. I did get into feelings of all kinds, feel good or feel sad or feel angry, when my vision started to change, but I had no idea what was in store for me before hours of clear vision began. I now tend to believe that for high myopia, success with VT may be, at some critical point, not just emotionally drastic but outright life-threatening. (And I'm sure it's always the case with laser surgery btw.) It removes a MAJOR, fundamental defense mechanism. (And laser surgery removes it SUDDENLY. One is plunged into his own unconscious feelings without a warning and with no chance to understand and integrate them. That's why psychiatrists are beginning to admit perfect-sighted post-laser patients with acute psychosis!) Not removing it

will mean not improving -- not significantly anyway. Removing it means not only a lot better physical eyesight but, invariably, insights and understanding -- and deep terror that has to be dealt with. Why am I not speaking "for myself only?" Well I may be wrong, but presently, I don't see how anyone could have become seriously myopic for mild, innocuous reasons, and how anyone can get out of myopia by applying mild, innocuous measures. There's nothing special about my case to make it an exception. I think it's true for every case that energy expenditures either way must be equal, i.e., whatever went into making myopia has to go into breaking it. I've been looking for a way around it and there's none. We live in a goddamn symmetrical universe.

>3) My exposure to the Alexander Principle has shown me how deeply >ingrained bad habits can be, but how they can be changed by >thinking in the correct way.

I've read the book you recommend. I believe the physical part of the Alexander technique may constitute a step in the right direction (and so can yoga, and probably the neo-Reichian techniques, and probably Rolfing -- any good old body-inclusive stuff that is at least closer to reality than the talking/thinking/behavior-modifying "cures." But I doubt it will let anyone go all the way. As for thinking the correct way -- again, I agree it's a good start. But between a certain way of thinking and a certain way of physical functioning, there's a missing link, a broken connection. It's the MEANING. It's the original FEELING that has forced one to adapt a "bad habit" in the first place -- its totality, not just its representation on the thinking or physical level. Unless that broken link is restored the total normal function can't be restored.

>What do you think?

I think a marriage between Primal and Visual Therapies would be the greatest anti-myopic alliance in the world. I think Primal is the only therapy that doesn't deal in unrealities and wishful thinking, and the only one that is true Science (and I do capitalize, to differentiate from the kind of science I've been dissing so far in my posts), rather than a liberal art every other therapeutic practice has always been. I think Primal alone can't cure myopia because of the vision-specific technicalities they aren't familiar with (like Batesean methods for restoring healthy looking habits and what to do about glasses and the use of transitional lenses and so on). And I think VT alone can't cure (as in, CURE) myopia because it can't, by itself, get down to the root cause. I think I would be ready to cure every myope in the world (well, almost...) after taking a formal course of training with Dr. Janov. Any idea where I could apply for scholarships/grants/donations?

My experience and my belief is similar to yours in that i dont feel past trauma is a major source for my condition, though i have experienced a good deal of liberation from these meditations. Why does it have to be One model or another? Could not one person have an especially traumatic event which is hanging them up, while another has particularly stress producing habits of life, or a stress causing belief system, or another an excess of stressful visual conditions? The common denominator of all of the methods and theories is that the musculature is spastic and that this is an ingrained stress reaction.

Wouldn't a complete therapuetic approach be to systematically engage every method and gain whatever benefit it holds? The biggest surprise for me in getting involved in this VT is that the vision has become a small part of the whole job, my sensitivity to and effectiveness within the world is the bigger prize. I'm simply interested in ANYTHING and eager to get involved with it ALL.

>

Seers,

I know I'm currently into saying things that will appear quite far-fetched and unwarranted to many if not all. Like, successful VT may be life-threatening and laser surgery may cause psychosis. Well... at least I have a respected authority to back up these claims. William Bates, M.D., our mutual godfather, happened to suffer severe amnesia and possibly what-not while into his own vision improvement. He disappeared from his home and was accidentally discovered, about a year later, in a mental institution across the ocean, in England I believe, where he had been first admitted as a patient but rapidly promoted to doctor's assistant, working under a different name and with no clue in his memory as to who he really was. He had to re-learn his identity before resuming his successful practice in New York and writing his book and doing many other wonderful things.

This mysterious episode (I may have forgotten some details -- you can review the NY Times obituary on i\_see's home page to verify) is no longer any mystery to me.

Nobody represses good memories.

Elena

>Also, why leave cylinders out? I've read around and haven't heard any  
>reasons for that except that cylinders "distort vision".

Back in 1980 when I was 29 I got this:

```
R -6.50 -0.50 x 87
L -4.75 -1.25 x 137
+1.50
```

The doctor told me that "It might take some time to get used to them."

I never thought that I could see any better with them than I could see with my older glasses before I got the newer ones, but unfortunately, I wore them for 2 years before I went to a different doctor and got these:

```
R -5.50
L -4.50 -0.50 x 135
+1.25
```

These were MUCH easier to wear. For many years I thought that there was something bad in my glasses along with the good stuff that I needed. Finally I found out what it was, the damn extra cylinder. For me, and I assume others, the "flip over lens test" where the doctor keeps asking, "which is better, 1 <click> or 2?" simply does not

work, and leads the doctor to believe that I "want" more cylinder than I need.

Now I wear:

R -5.75  
L -3.50  
+1.25

and I have 20/25 in my left eye, 20/40 in my right.

I think unnecessary cylinder is evil.

Is THAT what all that "Which is better, this one or this one?" was about!?!?! I never could decide, but being the obliging patient, I always picked one. I would try so hard to see a difference, too!

I have learned that my vision is more dynamic than any pair of lenses could be. It clears and blurs and clears again. The astigmatism comes and goes, too. It seems to me a mistake to put a static correction for astigmatism (especially considering the "which is better...?" thing) when I know I don't always "need" the same correction!

Bravo, Mary! You beat me to the punch! I always thought that the "this one or that one" game was a fine tuning for diopter value. Live and learn. Now when I go back to my doc for new glasses, I'll tell him that I'd rather not play.

- Larry

it happens night and day. I think what you said about the curvature of the  
cornea is correct but why/when did it happen? is it because of VT? how could  
it be corrected?

Why does it go away when I put the glasses on? Does the cornea change shape?

Sorry, can someone explain a bit more about how this test is related to astigmatism?

Since astigmatism is related to seeing horizontal lines better or worse than vertical (and the rest of the degrees of the circle), how can an 'is this better?' test work? The tests that I've had haven't been one set of lines (eg vertical) compared with another (eg horizontal) - they've been a black circle on a green background compared with a black circle on a red background. Or is this a different test entirely?

I suppose it is too much to expect that Elena knows all about miners' eyesight??!!!

Caroline

-----

I believe there may be a connection here. Even though coal miners work with artificial light deep underground, much of their job is spent in semi-darkness. They must have a higher degree of night vision in order to remain productive in such an environment. You could probably add to that amateur (or even professional) optical astronomers who sit in vast darkness to snatch a look at their prey!

"Richards, Caroline" <[richardc@SYDNEY.BTAP.bt.com](mailto:richardc@SYDNEY.BTAP.bt.com)> wrote:

>Do you have a 'normal eyesight' side to your survey? Who are your control  
>people?

Caroline,

control groups are used in experiments I believe, not in surveys. I took a group of myopes but I didn't inject its members with a new experimental drug, or keep them on a special diet of carrot juice -- in which case I would need a control group of MYOPES again, to study the effects of the drug or the juice. A survey gathers information about a certain group (be it myopes or gardeners or voters) in order to find out possible statistical patterns, trends, etc., WITHIN the group. If I included normal-sighted people it would mean pre-centering the survey on the issues of birth (since all the questions about the patterns of wearing glasses and power of correction and age progression of myopia and circumstances of its development would be rendered meaningless). So it would have to be a different survey, where the factor that's being studied would have to be something common in members of THAT group -- birth factors, e.g. -- and if myopia were to show up in connection with some and not with others, then myopia itself would be a pattern discovered in THAT kind of survey. In mine, the common factor on which the survey was pre-centered was MYOPIA, and the pattern that showed up was the difference in abnormal birth statistics and overall traumatic experiences between low and moderate/high myopes.

>(And just out of interest, how big is the sample so far?).

Twenty from i\_see and seven from myopic acquaintances. A few responses had to be disregarded for lack of information on birth issues.

>That's why psychiatrists are beginning to admit perfect-sighted post-laser  
>patients with acute psychosis!  
>FASCINATING - ANY MORE INFORMATION?

I know of three cases, one from a friend who is a psychiatrist, one from e-mail correspondence with a member of a psychology-related group, one an acquaintance in Canada who attempted suicide. You must realize that although for the past fifteen months, I've been living and breathing the riddle of myopia and have turned myself into a one-woman research institution operating on a zero budget, my opportunities for large-scale research are somewhat limited. 99% of my efforts so far have taken place in my head, and whenever they seem to predict a trend, I try to check it out against the events in the outside world, assuming they may either support or disprove my findings, and getting by with as much support or refutation as will come my way. Presently, I trust what I get from this source enough to predict that the trend will continue; that the group especially at risk will be high myopes; and among those, especially the ones who had difficulty tolerating glasses, or somehow managed to NOT wear them full-time prior to the surgery. I also predict a percentage of neurological complications in some of these cases, in addition to the psychological and psychiatric ones. Proving or disproving it is a matter of medical statistics taking a look in this particular direction.

>  
>ANY INFORMATION ON THE EFFECT OF PRIMAL THERAPY ON EYESIGHT?

I mentioned that I got a "yes, in some cases" from the Primal institute when I wrote them with the question. I also read a number of Dr. Janov's patients' case histories (though I can't say in which book specifically since I've read five of them) and some of them mention vision improvement. In particular, one woman wrote that she'd been wearing glasses since her teens and her vision was getting steadily worse; in therapy, she lost her glasses at some point and was walking around with normal vision, but so busy with other things happening to her, that she managed not to notice it till two weeks later.

No specific Primal/Visual studies were conducted so far. The source of such studies is something I intend to become, if I manage to figure out the practical side of this quantum leap (the theoretical is, to me, at this point, a certainty beyond a reasonable doubt). I couldn't have predicted that things would come to this when I first e-mailed i\_see with an innocent bit of curiosity: "What is palming?" All I wanted was to try to stabilize my vision if I could and avoid getting a new upgrade for my glasses, something that was looming and distressing at that point fifteen months ago. And here I am, bent on getting training in order to become an "alternative alternative school of VT," of all things. Isn't vision improvement

fascinating.

Hello all:

My eight year old son has recently failed his vision screening test at school. One optometrist has diagnosed his vision problem as four diopters of astigmatism; another said 2.5 diopters of astigmatism. Does anyone know of any eye exercises etc which might lesson this problem?

Thanks ,  
Owen

Seers,  
i wanted to add something to the palming discussion that i thought of while palming recently. This connects to my peripheral vision comments previously; the continuum of light as opposed to objects, the 'feeling' of the visual space, and seeing extra dimensions in the objects looked at.

The total darkness one tries to create while palming is a chance to see no-thing. The awareness of the blackness corresponds to the awareness of limitlessness and infinite possibility. This concept taken to its full extent opens up a new side of reality not commonly recognized. In my case of myopia, this opening has contributed to much new clarity. The subtle boundaries and definitions we recognize and agree and steer ourselves in respect of; physical laws, moral imperatives, personal abilities (including our vision limits), are given new perspective in the consideration of the limitless blackness.

When not palming, seeing the Space between the Things rather than the Things in a visual field, imagining the incredible confluence of events leading up to the moments we're viewing at any time, and the incredible unpredictability of Nature, stimulates a similar opening of awareness. This awareness is of a different order than the logical type, but very powerful and very valid and an excellent compliment rather than a threat to the logical. It needs to be experienced rather than looked at from any logical stance, the concept of no-thing excludes any definition by definition:>

I believe that developing this awareness is critical to vision because it has produced huge gains for me recently. After 28 years of wearing glasses, (this along with many other efforts, this thread is just the most noticeably stimulating) my Rx is -3.5/-4 but for over two weeks i've been

seeing 20/20 flashes constantly, with the rest of the time mostly at near-perfect vision. The past three days i've worn my specs for only one 15 minutes job late last night trying to fix something deep in my car engine under flashlight, i was fine for a while but was getting frustrated with the job and began to strain. No glasses today despite a busy work day and driving, two activities that often break me down.

In a recent conversation with a friend of mine, (also moderately myoped since teen years) i learned that we had similar experiences.

Both of us had refused to wear our glasses for a length of time, and both of us had the same results. After not wearing my glasses for 2 months, i had to go back to the optometrist for MUCH stronger glasses, (before -3, after -5 approx).

My friend had also refused for a few years and gave in finally when he couldn't see the blackboard. His new glasses were very much stronger also.

Does anyone have a theory for this? From what i have been reading lately, the theory goes that by taking off our glasses, our natural vision will improve, but that wasn't my experience, nor my friend's.

While it's true that neither of us performed any VT during the time, i'm wondering if it might be a bit irresponsible to tell kids just to stop wearing their glasses.

Does anyone else have similar experiences or explanations why i might have had such a rapid deterioration in a short period. As far as i can remember, there was no unusual stress for me that summer.

Funny you should ask. It never occurred to me before that I do have two cents' worth of observations on this particular subject. Before coming to this country in 1989, I spent the first 32 years of my life mostly in a city that's one of the largest coal-mining centers in the world. The miners there (especially the older ones) have the kind of eyes you can't help noticing, because they have coal dust dislodged in the skin between their eyelashes, kind of like permanent make-up -- and heavy. I don't recall ever seeing a miner who was wearing glasses. (Contacts were not common -- I got mine sometime in the mid-eighties, and it was considered kind of fancy.) The city's population is over a million and its 40 or so mines were the No.1 employer of males.

- 

I\_seers,

When using an eye patch, how do you determine if you should cover the weaker eye or the stronger eye ? It seems to me if you cover the stronger eye that it would most likely improve the vision of the weaker eye, however at the same time you would be covering the stronger eye, thus imitating palming, sort-of. Would it be better to relax the weaker eye by covering the it or exercising the weaker eye by covering the stronger eye. Can you do both, without being totally blind ?

I'm kind of caught in the middle.

Thanks in advance,

Peter

I can't give an exact dioptric value, but yes, low amounts  
of blur (myopia) can be "interpreted" by the brain into a clear image.

According to some, even moderate to high amounts of myopia can be tolerated by the brain. Thus, the refractive error of the eye (ie, the elongated shape) may still be there, but the person can see 20/20 when "theoretically" they shouldn't be able to. What this means in practice is that an eye doc can use the retinoscope on a person and get a refractive error that would indicate the need for lenses to see clearly. But in cases of myopia reduction, the person can learn to see clearly anyway.

Herb,

Is there any evidence of there being an emmetropization process with astigmatism? Is there any indication that it can be good for one's vision to undercorrect astigmatism? What I've heard is that no, one might undercorrect astigmatism in order to make glasses easier to wear, but one wouldn't expect small amounts of astigmatism to self-correct.

How important is it for the plus lenses to have the right PD? ( I saw the ones in CVS listed 62 mm PD, and I know kids have less PD).

Relative plus or simply plus 1 lenses are good for kids who have moderate myopia?

The following article is from School Myopia: a Preventive and Remedy by Jacob Raphaelson, O.D., Copyright 1958.

It is just one of several sources that confirm my suspicion that astigmatism is just another product of eyestrain, and is curable by regularizing the tension of the extraocular muscles.

There are several conceivable ways of going about this. One way would be to assure that the eyes move freely in all possible directions, for example, by following lines in a maze. Another way is biofeedback. Dr. Raphaelson found that plus lenses with NO CYLINDER COMPONENT would actually cure astigmatism. Below he explains how...

-----  
WHAT ABOUT ASTIGMATISM?

I have been asked many times the following question: how can I give a pair of plus 1.00d spherical glasses to a child without examination and without finding out whether or not he has astigmatism? Let me tell you about this. I have been pondering this question to myself for many years. It was only a few years ago that I came to a conclusion. It is not only proper to give spherical plus glasses to a child who seems to have astigmatism, but it is, in reality, the best thing to do.

I came to this conclusion because I now believe that astigmatism, like myopia, is an unnatural development of the eye due to our near-vision environment. Astigmatism, like myopia, develops during school years because of the prolonged and intensive bending of the eyes during those

years, and also because natural hyper-sighted eyes are given no opportunity to relax and to stretch.

Let me quote you a report by Dr. E. W. Adams, O. D., to the Optometric Research Institute. He says: "We have been surprised to find that the percentage of pupils with astigmatism increases during the successive years." He reports also that in the first and second grades very little astigmatism is found, but after these two beginning grades each successive grade up to about the sixth increases the percentage of astigmatism; after the sixth the percentage remains about the same. Dr. Adams also reports that from their research they have the feeling that myopia is increasing.

This report was the result of a survey and a thorough examination by highly capable optometrists with suitable testing equipment. In the years of 1935 and 1936, 6,560 pupils were examined in eight public schools in Detroit, Michigan.

This report is not the only basis for my conclusion about astigmatism. I have many other basic proofs from my own experiences and observations. I also have reports by other optometrists which concur with my conclusion. A pair of plus 1.00 glasses for a child for near work is much safer and more beneficial than a minus 0.50 or even plus 0.50 cylinder glasses.

#### NOTES

Nearly ninety per cent of astigmatic eyes are of the low grade type, that is they are fitted with cylindrical lenses of less than one diopter (1.00d) either plus or minus. In most cases, the wearing of plus spherical glasses would reduce or cure the astigmatism and eliminate the need for cylindrical lenses.

My advice to parents would be to have their children wear a pair of plus one (+1.00D) spherical glasses for at least one year before they allow their children to be fitted with cylindrical glasses.

I broke my glasses once about 8 or 9 years ago and thought i would make this my instigation to finally rid myself of glasses. I forced myself to deal with evrythng without them and didnt do well at all. After 2 weeks I finally went and got new glasses and fealt a failure (i dont remember the new Rx, i never have kept good record of that, but it wasnt much stronger than the old one). My theory for your experience is that TRYING to see and the angst produced by being unable to causes a great strain. Currently i am not wearing glasses much at all but i have a policy of \*whenever\* i find myself NOT seeing well and WANTING to, I put them on immediately. sometimes you just need to retreat. Vision occurs best with NO EFFORT. Also, i doubt if the new vision will occur without the therapy, it's a personal discovery that cant be just read about.

As far as I know, all current research on blur-induced myopia has been done on animals, chicks and shrews primarily. And the blur in this case is usually some kind of frosty lens, NOT an undercorrection or "reverse prescription." In other words, no amount of focusing can improve the vision. It is not the kind of blur that can coax one into being less myopic, like the blur myopes see when they take off their minus lenses.

It is true that myopia is observed to increase when they give the chicks super-high-power plus lenses, say 8 diopters. In this case, it would be to the chick's advantage to become more farsighted but instead it becomes more nearsighted. There are two theories to explain this. The first is that the action of accommodation cannot overcome the blur and therefore the eye "grows" more myopic in response because the visual development system interprets the blur as a sign of farsightedness. The other one is that the blur is so great that the animal doesn't know what to do about it. It tries to overcome it by focusing for near instead of the reverse, and brings about axial elongation by the action of the accommodating muscles.

But no one--NO ONE--has done an experiment where half the people diagnosed

with a diopter of myopia are given full corrections and the other half are given plus lenses. NO ONE has done an experiment where, say, 100 people with 3 diopters of myopia are forced to go without their glasses for a month. The research on blur-induced myopia cannot be applied to vision therapy.

How much blur is TOO MUCH blur? I don't know, but it is my steadfast belief that extremely large amounts of blur--say, that provided by a 3 or 4 diopter undercorrection--can be very beneficial in treating myopia. The important thing is that you are conscious of your ability to change focus, that you can imagine yourself seeing better. The presence of blur in itself does not cause you to eliminate it. But large amounts of blur can be great as biofeedback. When things are just a little bit blurry, then you can get by. Up the challenge--increase the blur--and if you have a taste for sharpness, your eyes will want to refocus. You may have to help them, though...

I have just recently had amazing results by wearing 3 diopters (one +1 lens on top of a +2 lens) and doing Bates's "swing" exercise, which is swinging your head back and forth with your eyes open, watching things go forth and back, not fixing your eyes on any one object, but just letting them all pass by. I am normally about a diopter myopic, so this amounts to a +4 "add". If you wear a 4 diopter prescription, then the equivalent would be to just take your glasses off. The results for me when I took the glasses off were an amazing increase in clarity and reduction in those mysterious astigmatic ghost images. Plus, my eyes felt a bit more "snappy"--hard to describe

Just a quick note on this one (as a fairly regular s.m.v. poster). The cornea is aspheric to begin with, so it has different curvatures at different points. To find out whether the cornea is abnormally shaped one needs corneal topography, not autorefractation. I hear that corneal topography, previously reserved to medical and PRK/LASIK centers, is now making its way into optometrists' offices. A cost I have seen quoted is \$25 for this service. George will have to look for an OD with a corneal topographer (mapper), as there are not many around at this point, at least in the US. If you bump into terms like corneal mapping or videokeratography, they all refer to the same thing. You'll get a neat looking map, usually color-coded, with areas colored according to power.

On another note, I got really moved and inspired by Bill's recent post "palming-darkness". I have something interesting to report too, but will do that after I complete the 'experimentation stage' in about a week.

Best,

Stefan

So what you are saying is that high myopia cannot be "stabilized" by taking off specs, it will only get worse. Thus the brain attempts to restore 20/20 when the myopia is around < 1.75D?

Oh dear, I have to disagree! (and this was such a friendly list :-)  
Bates does talk all the time about "mental strain", but implies that  
it can frequently be relieved, not by feeling an original pain, but by  
one of his exercises. My hope is that the following quote from his  
book "Better Eyesight Without Glasses" will come true.

"In some cases five, ten or fifteen minutes is sufficient, and  
I believe the time is coming when it will be possible to relieve  
everyone quickly. It is only a question of accumulating more  
facts and presenting these facts in such a way that they may  
be grasped quickly."

I was sceptical when I first read this, but I'm beginning to think  
it will come true.

<snip>

When I've won our National Lottery, you can apply to me as long as I'm  
the first to be treated. I haven't yet bought a ticket this week as I  
read that you have a greater chance of dying than winning when you buy  
it at the beginning of the week.

Nick;

It depends on the age of the person with astigmatism. With young children, many think its best to either not correct the astigmatism or to undercorrect it because it will often self-correct with time. With adults, I have heard nothing like that. Some people think the astigmatism of young adult years comes from the action and pressure of the upper lid squeezing the eye and thus causing the usual axis 180 cylinder. Older folks then tend to have their axes change direction closer to 90 degrees with the relaxing of the upper lid pressure with age.

Congratulations on the eyesight improvement! I wish I could answer your question, but I do not have the experience yet to know. I would recommend contacting someone who has more knowledge in this area, perhaps Dr. Kaplan on this list?

Interesting! I had an utterly different sort of experience about 10 years ago when I was doing restaurant work in California and decided to leave my glasses off. I spent my time walking, swimming and working, and when I came back to Tacoma to see my eye doctor, he said that he couldn't understand why my eyesight had stayed so stable, and something to the effect of "it shouldn't have happened". What?! Anyhow, I suppose there must be quite an assortment of factors....hard to say! The longer I'm plugged into this list, the more convinced I become that the path to clear vision is frustratingly different for each and every person, and requires a large commitment to see results. We have to figure out every little detail for every little step. What a job! :)

Linda;

The current research seems to show that myopia may progress when there is an unusually high amount of BLUR. So if you use low plus lens for myopia reduction, that is okay. But if you have several D of myopia and take off your specs, that is too much blur. The emmetropization process (which is the body's natural way to keep vision at "20/20" only seems to work with mild amounts of blur.

Me too. As an example, I found that my peripheral vision had been very limited, but as it improved I became better at "seeing" the wider view in non visual parts of my life.

>The Lieutenant-Governor of British Columbia (the Queen's representative) has proclaimed August to be Blueberry Month in British Columbia. Blueberries, a fruit native to North America grown commercially in many states and provinces, are truly fit for a queen. What's more - they are good for her too.

>

>The blue in blueberries comes from the anthocyanin pigment. Anthocyanins are called phytochemicals - phyto from the Greek word for plant - or nutraceuticals because they act as antioxidants protecting body cells against undesirable oxidative changes. Anthocyanosides prevent free radical damage with antioxidant and free radical scavaging action.

>

>The North American blueberry is related to the European bilberry (*Vaccinium myrtillus*). Bilberries have a very high anthocyanin content because the pigment is in both the skin and the flesh. In the North American blueberry, the pigment is only found in the skin. For that reason, small berries have proportionally more anthocyanin because the proportion of skin to flesh is higher than in large berries. Because wild (lowbush) berries are generally smaller than cultivated (highbush) berries, the anthocyanin content of the lowbush berries is generally higher.

>

>Bilberries have been used in folk medicine in Europe for centuries and extracts of bilberry (sometimes mixed with blueberry extract) are sold in health food stores in Europe and North America. Scientists are now actively investigating the health benefits of the anthocyanin pigment in bilberries and blueberries. Promising research areas for the use of extracts from these plants are in ophthalmological applications, diabetes and inflammatory joint disease.

>

>Dr. Willi Kalt, a plant physiologist from the Kentville Agricultural Research Station in Nova Scotia, who is studying the anthocyanin content of blueberries provided the following comparison:

Stefan,

I just came back from a corneal topography with an optometrist who uses orthokeratology.

The result as far as I could understand (since he was the kinda 'know-it-all' optometrist) there is some 'extra' curvature at the top and bottom of the cornea the way I expected to be i.e. it's just like it's squeezed by vertical up and down pressure. This confirms my theory about the double images that I'm getting.

What to do next next? I guess I'm looking for some suggestions on how to exercise a horizontal pressure to minimise the curvature sort of what OK is supposed to do.

george

I_seers

For me, when i do palming and see images in my mind they are rather blurry. Sometimes although the images may become clearer for brief periods of time. I wondering if this may have something to do with me being high in myopia. Do other high myopes experience the same ? Do lower myopes experience more sharpness in the images they picture in their mind then the higher myopes during palming ? If this would be the case it would lead me to believe that myopia has a lot more to do with the brain as oppose to the eyes then i first thought. Maybe when we would see images in our mind become clearer it would show that the effectiveness in our palming would be increasing. As well if this is the case, maybe this would be another way to test the effectiveness of palming, by images becoming sharper in our minds then they usually are, it's sort of like clear flashes but only in our imagination.

What are your comments on this theory ?

Thanks in advance

Peter

This is a question that I have been pondering for the last three years now. About three years ago, I stopped wearing glasses or corrective lenses except to drive. This was prompted by reading a book on Vision Improvement by Janet Goodrich. With an Rx of -5.75Rt, -5.25Lf, my vision was fairly blurry. After three years, my vision has improved to about -4.00Rt, -3.5 Lt for 20/20; but it has been a slow and at some times imperceptable process. The question that always bugged me was : Do the eyes require a certain amount of clarity in order to attempt to focus? Would my progress be faster with an undercorrection of one or two diopters? You have indicated that this is the case, but my aversion to wearing minus lenses of any strength is almost too strong to overcome.

-

I_seers,

When using an eye patch, how do you determine if you should cover the weaker eye or the stronger eye ? It seems to me if you cover the stronger eye that it would most likely improve the vision of the weaker eye, however at the same time you would be covering the stronger eye, thus imitating palming, sort-of. Would it be better to relax the weaker eye by covering the it or exercising the weaker eye by covering the stronger eye. Can you do both, without being totally blind ?

I'm kind of caught in the middle.

Thanks in advance,

Peter

I usually experience inner visions as sharp and clear
(I have a high level of myopia). If they are fuzzy,
then they are usually an energy swirl or something where
I would not expect a crisp, worldly image. How about when you
visualize something when not palming? Are your dream
images clear? Maybe I don't understand your description.

I wear 20/20 correction sometimes just to experience the
unsurpassable beauty of the world. I wonder, though, if
putting on the glasses is simply a way to evoke a habitual
response of ordering the world a certain way.

I'm afraid that I will have to present myself as a counter-example to your theory. I find that the images in my mind are always of crystal clarity. The only time there is a blur is if I am remembering a scene which occurred when I wasn't wearing any corrective lenses. I currently have approximately 6 diopters of myopia in each eye and have been myopic for nearly 30 years.

Hi All,

I looked up where I saw the thing about acupressure...

it was in Dr Liberman's book 'Take off your glasses and see'

pages 26 and 27 show " EYE EXERCISES from the People's Republic of China"

there are four exercises to do twice each day involving pressing against certain points on the face.

He says that the Chinese have actually reversed the increase in Myopia.

The exercises were endnoted to : Hazel Dawkins, Ellis Edelman and Constantine Forkiotis ' Suddenly Successful: How Behavioral Optometry Helps you Overcome Learning, Health and Behavior Problems' p 85

Alistair Phillips

True, one of his exercises RELIEVED my own myopia the very first time I tried it. I'm not talking relief though, I'm talking cure. Bates himself CURED his vision. Why did no member of this list succeed to this extent by following in his footsteps? So many motivated people, so many valuable approaches, so many encouraging cases of improvement... but no cure?

Hypothesis: Bates's exercises work to their full potential only under certain specific circumstances and only on one condition: when they lead right into a direct feeling contact with the original pain, the one that was the reason behind visual system's original defensive response and its subsequent chronic defensive functioning. The pain (emotional or physical or both) may be so catastrophic that, once stripped of its original defense, the body and the mind will desperately seek a new defense in order to shut the feeling away from consciousness again. THAT'S WHY BATES HIMSELF GOT AMNESIA IN THE PROCESS OF IMPROVING HIS OWN VISION. He came up with his intuitive idea of "mental strain" (something rather vague and not terribly threatening from the sound of it) on the intellectual level and, while staying on THAT level ONLY, was free to slice it any way he wanted -- call it "fear of not seeing" or "anxiety" or "too much effort." But when up against a full blast of total three-level consciousness of the original feeling, he himself was powerless to handle it. The memory his exercises brought him into contact with was so agonizing that the only way to defend against it was to sacrifice his WHOLE memory to total amnesia. It was just a NEW defensive tactic of a mind stripped of its OLD, visual defense -- and driven desperate by a catastrophic feeling as a direct result of it.

Amnesia is the best way to make sure that something "never happened."

Let me borrow Larry's favorite line here: Hmmmmmm...

The great man himself was a believer in the magic bullet... even though he
should have known better, after his magic bullet went right through his brain!

>When I've won our National Lottery, you can apply to me as long as I'm
>the first to be treated.

Agreed -- go get that ticket. For now, I don't see a way to make things
come true by just wanting them to, but the next best way -- to make things
come true by knowing precisely how to work on their coming true -- is just a
lottery ticket away :-)

Elena

I've found these helpful in releasing facial tension.
I try to do them at least once a day.

Another counter-example. The images I get are of neither crystal clarity nor uncorrected blur. They seem to fall somewhere in between where I can see the image, it is clear to me what the image is, but yet it is not the type of crystal clear image that I would expect. Funny though, no matter what the image or the "blur" factor, I always know what it is.

Damn, if real life was that way, no more glasses!

Yes, you have to give up the part of yourself that
"knows" that you cannot see clearly things that are 20 feet away.

We don't need to sacrifice a part of ourselves, we need to REGAIN some things. I might need to get rid of some things that are not really me, such as faulty beliefs, mistaken perspectives, automatic assumptions I have picked up along the way. I am learning to question things that I have long taken as fact (it helps to spend time with children: they ask why all the time). It is scary to think that I might have to become someone else to "get better" (ask anyone who has been through a 12 step program about that). That is not how it works. This is not electro-shock therapy.

<snip>

This statement is, perhaps, overdramatic, since it cannot be verified. The biography does not mention if his amnesia occurred before, during, or after he cured his vision. Also, it is nowhere mentioned if he received psychiatric help following his memory difficulties. This means that we have no way of determining what was going on in his life at that time. Amnesia of the sort that Dr. Bates suffered is still not a well understood phenomenon. While there may be some validity to your conclusion, I don't think it is deserving of the strong emphasis that you have given it.

>Is it
>possible that in order to effect a cure, we may have to sacrifice a
>part of ourselves in the process??? Is that REALLY necessary???

Yes. The part that has to be sacrificed is our defenses. The magnitude of the "sacrifice" will be in direct proportion to the original amount of refractive error. (It doesn't mean high myopes have more defenses overall, as people: a low myope -- or a perfect-sighted hypertension sufferer or alcoholic or worcaholic or whatever -- may just be someone who utilizes a larger VARIETY of defenses -- i.e., myopia plus stiff muscles plus a stiff, impenetrable armor of beliefs, for one -- whereas it is also possible, like in my case, to have more homogenous defensive responses, when everything sort of gets absorbed by a single major defense, myopia -- my body's preferred method of warding off whatever it felt I couldn't deal with and had to defend against.) And "sacrifice" is an appropriate term because a defense is NOT something easy to give away. It ain't charity unless it hurts.

What gets sacrificed when one loses defenses is the unreal self. I don't mean anything symbolic by the "unreal self," I mean the part of us that developed in response to the early manipulative intrusions on our reality. An example: when I discovered I had to investigate my childhood for what I might not know, I was looking through some old photographs and found a few that showed me, at the age of about three, invariably holding things in my LEFT hand. Holy sh...t, and I've always thought of myself as emphatically right-handed! It never even crossed my mind that I might be anything else. So I started questioning my parents. My mother didn't remember anything; my father said, "Oh yes, you did want to do things with your left hand but of

course we taught you the proper way."

Of course. So now I know the reason behind my contra-lateral (right hand/left eye) dominance, something PHYSICAL but brought about by PSYCHOLOGICAL pressure. Now which "self" is real for purposes of this one tiny distinction -- the left-handed, laterally dominant me or the right-handed, cross-dominant me? Which brain organization is real, incidentally? Obviously there's an alternative -- and none of my favorite fuzzy ways around it will work -- I have to choose one out of two! So which one is the real self? One has to be chosen, the other one sacrificed. What do you think?

It's only one little example, nothing major. Each and every one of us consists of myriads of such "realities" that are really unreal and were absorbed into "self" by pushing out bits and pieces of the REAL self. Bits and pieces till there's nothing left of the original, master-plan, undistorted us but a system of defenses. Is it worth it losing it? Is it worth it to be real?

Peter

I thought that the idea of palming was that you weren't to imagine/see anything other than blackness. I'm a low myope and I see speckles of grey or red sometimes, but no images. Are your images unbidden, or do you deliberately bring them up?

Caroline

For me, when i do palming and see images in my mind they are rather blurry. Sometimes although the images may become clearer for brief periods of time. I wondering if this may have something to do with me being high in myopia. Do other high myopes experience the same ? Do lower myopes experience more sharpness in the images they picture in their mind then the higher myopes during palming ?

Peter

My question too. I was going to ask it last week and then forgot. The only information I have is that my behavioural optometrist originally told me to patch my eyes equally (they are 3/4 D different from each other).

However, I have often wondered whether to give my weaker eye more unpatched time than my stronger, because I've heard that your weaker eye will never 'bother' to improve too much while the stronger one is there to take care of things.

When I told him that I found palming difficult but often managed to cover just one eye whilst on the phone at work, he said that that was good, but it wasn't palming, it was effectively patching. (Is this because the covered eye is moving as the uncovered one is, even though it can't see anything?). Hence your "thus imitating palming, sort-of" would seem to be incorrect.

>From that I concluded that both eyes need to be covered for palming. (Why? Is it because it is more of a brain and relaxation thing than an eye thing?).

If anyone else has an answer about patching the stronger eye more than the weaker I'd be fascinated to know.

(NB I don't actually know why I was told to patch my eyes, but I believe it was more to do with increasing peripheral vision, which is apparently required before 'normal' vision improves(??) My optometrist also told me

one of the most important things about patching was allowing the feelings to come out - eg frustration when you misjudge distances!)

Caroline

When using an eye patch, how do you determine if you should cover the weaker eye or the stronger eye ? It seems to me if you cover the stronger eye that it would most likely improve the vision of the weaker eye, however at the same time you would be covering the stronger eye, thus imitating palming, sort-of. Would it be better to relax the weaker eye by covering the it or exercising the weaker eye by covering the stronger eye. Can you do both, without being totally blind ?

I'm kind of caught in the middle.

Thanks in advance,

Peter

Elena,
While i can relate to your statement of 'non vs. real self' I think the concept requires deeper analysis. The concept of a 'Real' self and a 'false' self is a classic dichotomy which aint necessarily so. Consider that any concept of Self is a false creation by virtue of it being a concept. This creation is a static snapshot of an aspect of Self which fails to contain the infinity we are, and also fails to properly express the fact of the constant change which is essential to a living thing.

Therefore the so-called 'True' self, while more favorable than the 'false' one is still not the whole enchilada and just as likely to create blocks to full awareness. the mind unceasingly refines it's snapshots, but they all end up in dusty albums. Better to abolish the practice of deciding what is one's 'true' way of being and focus on what feels good.

I know you have spoken eloquently on the importance of feeling, but the concept of a 'true' self has implications i wanted to point out. I liken this to the notion that there is a 'reality' that we can eventually fully understand, and since we are coterminous with that same reality, this will never occur (or maybe when we die, i'm not sure about this last point).

this is not to belittle the discoveries of our past tendencies and the way the changes we have adopted over the years have shaped our present structure, just to put a perspective on the information and again, to avoid the notion of a RIGHT way to be. (other than DOING what we DESIRE at all times:)

At 15:45 8/31/96, Elena wrote several things, including this:

...

>It's only one little example, nothing major. Each and every one of us

>consists of myriads of such "realities" that are really unreal and were
>absorbed into "self" by pushing out bits and pieces of the REAL self. Bits
>and pieces till there's nothing left of the original, master-plan,
>undistorted us but a system of defenses. Is it worth it losing it? Is it
>worth it to be real?

>
>Elena

my recent reply to Elena reminded me of a poem i wrote last week as it expresses the notion somewhat:

~~~  
the dark is still not black enough,  
a veil will never lift for the looker.  
being blackness, irridescence  
fills the void with a light  
alive and coming from nowhere.  
no ancient fountain  
nor shrouded mountain.  
timeless, sourceless, the star  
defies the sharpest sword.

~~~

>after he cured his vision.

Rather than believe that a balanced individual with no history of mental disturbances will suddenly lose his identity just for no reason, out of the blue, I think I can glean a causality. My theory of the nature of refractive errors as defensive mechanisms seems to offer a good working hypothesis of what, why, and how could have happened, and I view the fact that Bates DID start working on his vision improvement at some point as supportive circumstantial evidence. If I knew he started doing drugs I would suspect drugs. If I knew he suffered a blow to his head I would suspect the blow to his head.

Last but not least: I improved my own vision significantly and I have the kind of "inside information" about the process that makes it easy for me to understand its possible twists and turns in others. I'm aware of the fact that this statement is even weaker than "circumstantial," but this I can't help, it's the nature of the beast: whatever I say will be just something I say unless/until someone has similar experiences. (Unless of course this person is stricken by amnesia and forgets them on the spot! :-)

>Also, it is nowhere mentioned if he
>received psychiatric help following his memory difficulties.

It was in a mental institution that he was eventually found after his disappearance, and unlike Bates, his doctor didn't have amnesia and did give information about his being first accepted there as a patient. If my own

memory serves, there's two documents on the i_see home page, one an obituary and the other one a biography, and one of them mentions this fact.

Whether he received any help there is again open to speculation, but as a matter of common sense, I tend to think that someone who doesn't know who the hell he is and how the hell he got across the ocean and what for can be defined as a person in a little bit of trouble and in need of some kind of help.

>Amnesia of the sort that Dr. Bates suffered is
>still not a well understood phenomenon.

It wasn't then but it is now. It's been linked to PTSD.

Sorry for being late in responding. While I am not a cornea specialist, my understanding is that the cornea is *naturally* steeper in the central superior and inferior regions, the pressure exercised by the eyelids being the main factor put forward to explain this. With age as the eyelids become more "flabby" (I don't like thinking about that), this topology changes and in fact the cornea becomes steeper nasally and temporally (against-the-rule corneal astigmatism). So, if this extra curvature in the top and bottom regions is the only "abnormality" that was noticed, I think that it is pretty normal, assuming you are below 50. I for one have it, and prevalence of with-the-rule astigmatism less than or equal to .75 D is about 70%, if I remember right. This should not be a cause of noticeable double images, I personally don't have them.

I don't recommend wearing astigmatic correction for with-the-rule astigmatism below 1.0 D. I used to but gave it up six months ago. I still have the corneal astigmatism, though, but my brain filters it out pretty well.

So what could be the cause of the double images you are getting if not abnormal topology? Frankly, I don't know. Do you have them all the time, under all kinds of lighting conditions, emotional states, etc.? This is not to scare you, your case may have **absolutely** nothing to do with this, but consider the possibility of some optical neural problems or amblyopia (I think 'lazy eye' is the popular term), or ask around about other causes of deficiencies in stereopsis.

William Bates: The man, the myth

- *To:* I SEE <i_see@indiana.edu>
 - *Subject:* William Bates: The man, the myth
 - *From:* Alex Eulenberg <aeulenbe@indiana.edu>
 - *Date:* Sun, 1 Sep 1996 14:44:45 -0500 (EST)
 - *Sender:* owner-i_see@indiana.edu
-

Did Bates need to lose his memory in order to regain his eyesight?

I don't think so, Elena.

Bates actually did mysteriously disappear in 1902. According to newspaper reports, he left a note for his wife saying he had to take a trip with an old college friend, Dr. Fourche, a name his wife was not familiar with. In 1902, he was already a successful eye doctor, and according to the reports in the newspaper, was working on a book. There was absolutely no mention in the papers of Bates's attempts to cure defective eyesight without glasses. For a month there were rumors of Bates being seen at Charing Cross hospital, rumors that the hospital denied. His wife went to London in search of him. She reported to the newspapers that she found him at the hospital, that he had become very sickly looking, and that he had no idea who he was. A day later, according to Mrs. Bates, he disappeared again. It kind of makes you wonder who was doing the hallucinating.

Still, I have never heard a logical explanation of what happened to Bates in the Fall of 1902. There also were conflicting reports (the New York Times obituary says one thing, the Cyclopedia of American Biography says another) as to whether his wife died before he returned, or whether she lived into the late 1920s.

In any event, journal articles by Bates claim that he first discovered the principle that poor distant vision is caused by a strain to see at the distance in 1903, and that at that time he was in Grand Forks, North Dakota. He also says in his book that it was not until after he had done his experiments on the eyes of animals--published around 1915--that

he managed to cure himself of his presbyopia:

The first patient that I cured of presbyopia was myself. Having demonstrated by means of experiments on the eyes of animals that the lens is not a factor in accommodation, I knew that presbyopia must be remediable. But I realized that I could not look for any very general acceptance of the revolutionary conclusions I had reached as long as I wore glasses myself for a condition supposed to be due to the loss of the accommodative power of the lens. (Better Eyesight Without Glasses, p. 138)

So it seems to me pretty clear that if Bates did lose his memory as a result of his vision improvement, it was not during his famous disappearance.

Elena, or anyone else living in New York... go down to the New York Medical Library (or whatever it's called... it's right by Central Park) and look in the card catalog file they have on Bates. You can read the newspaper clippings there, I believe. I went there myself and saw the card they had, but did not request the materials as I had already uncovered much by reading microfilmed versions back here in Indiana.

> interested in your more spiritual /mind body technique.
>

Hi Hope,

Thanks for reading my post ..

In materialistic approach of solving problems we are given a piece of material as the solution to every problem. Glasses are the material solution to myopia. But this approach completely ignores that human beings are basically spiritual beings. Therefore most material solutions are not permanent and satisfactory solutions. A more holistic approach is needed in solving the problems which goes to the root of the problem rather than being a "slap-in" solution.

> I have just joined the list. I did some Bates exercises a couple years back but
> with only minor success. Then I tried a more spiritual /mind body approach,
> and have had many flashes of completely clear vision in a short time.

Bates exercises are physical and are not a complete solution of the problem on their own. First a complete change in mind-set, attitude, thoughts and habits is needed and then these relaxation exercises be performed from a more holistic point of view rather than as a five minute daily drill.

Bill,

I have a problem with skipping steps, is all. I don't mind being an
"infinity" and I don't disagree with the assumption that a "deeper analysis"
might eventually reveal that a distinction between my left eye and my right
eye and my left hand and my right hand is a false distinction, but I'm not
there yet. I'm in "this here life," for now, and that's where I intend to
operate before I venture into any "more real realities." However humble and
subordinate, I like my realities complete, I don't discard them until I'm
sure I understand them. Life, IMHO, is big enough and real enough and
misunderstood enough to warrant further exploration before going anywhere
beyond.

>

>Therefore the so-called 'True' self, while more favorable than the 'false'
>one is still not the whole enchilada and just as likely to create blocks to
>full awareness.

I would lend any "fully aware" individual a more attentive ear if his
awareness stretched as far as to accept the incredible idea that he,
personally, ever had a birth and an early childhood and an early personal

history. That his own this-here life EXISTED and was filled with feelings that had total power over his being and thus SHAPED him in a certain way long before the point where his conscious memories and conceptualizing abilities and "awareness" began. If this part is discarded and disregarded, the only thing his awareness will ever produce will be any number of increasingly elaborate replications of his basic, fundamental ignorance. If, on the other hand, this period of "becoming" is fully absorbed into his consciousness, he won't have any problem with true/false self distinctions: they will be laid bare in full view. Then we'll speak our common life-specific language of feelings, rather than jingle the small change of intellectual/religious/philosophic concepts. Those are a dime a dozen -- and a poor compensation for what we've been robbed of.

>the mind unceasingly refines it's snapshots, but they all
>end up in dusty albums. Better to abolish the practice of deciding what is
>one's 'true' way of being and focus on what feels good.

Things "feel good" for a variety of reasons. They say the manic phase of the MDP feels incredibly good; a shot of cocaine that interrupts withdrawal symptoms in an addict feels good; some people are of the opinion that killing other people feels good; finding faith -- any kind of faith that mitigates the otherwise unbearable here-now -- feels good. I don't mind feeling good myself and I certainly don't begrudge anyone his feeling good. What I'm driving at is, feeling good is no indicator of experiencing a "true way of being." It may be limited to a very superficial level, while the deeper level of reality is being ravaged by feeling horrible. Reminds me of an old limerick:

There once was a young man named Sidney,
by drinking he ruined his kidney.
It shivered and shrank
while he sat there and drank,
but he'd had a good time at it, didn't he?

There IS a right way to be. We are naturally perfect. I know what lies underneath all the "improvements" superimposed on our true nature from day one, beyond all our attempts to shield ourselves against the assault of those "improvements," beyond all our defensive functioning that is really malfunctioning out of necessity -- and I know it is perfect -- there are no monsters there at all, just a perfect, gentle creature scared into hiding. To scare our true nature into hiding is the WRONG way to be, even though it's long been a way of life for the whole species. A long history of being wrong doesn't make wrong a respectable variant of the norm, anymore than the existence of hundreds of millions of myopes makes myopia a "variant of the norm." Wrong is wrong.

Not trying to improve on nature would be the right way to be. Not trying to be what we aren't would be the right way to be. Letting our children be what they need to be, not what WE need them to be, would give them back the right way to be. And we would have to start very early. Beyond day one, it may already be too late.

Here's something that seemed to help me loosen up my eye muscles.

Take a yardsick and hold it at arm's length, pointing outward. (Make sure you have a lot of room!) now look at the end of the yardstick, like you're aiming a gun. Slowly swing right and left, keeping your focus on the end of the stick. Don't let yourself get dizzy, but do watch the scenery roll by. This is good for loosening up those eye muscles.

I am a patient undergoing OK/PCM for the last year and a half. The double images that you describe is a common problem during the molding process. It is not a problem when the molds are on. I chose PCM because I did not want surgery, and VT took too long.

My cost was \$1900 and each mold is \$80. All doctor visits are included in the initial cost. I always insist that when the molds are replaced that they are replaced in pairs.

I am happy with it. If I wasn't doing PCM, I would be wearing contacts.

Yet the distinction i am questioning is 'False Self and Real Self' This
distinction has pitfalls and doesnt share the same status of reality that
the right and left hand do.

Perhaps this communication breakdown occurs BEYOND the point of early
childhood memories, at a point where creation occurs, where LIFE occurs. I
am involved with that reality and it is not small change for me. Please
address the specific points rather than attack my qualifications for
speaking. I actually do know where your words issue from, and i also see
that paradigm's limits. Because you don't see it does not mean it does not
exist. (myopia alert)

We must resist the impulse to project our PERSONAL values upon another. Did

you see -Leaving Las Vegas- ? This to me was an incredible study of 'live and let live' among other things, (love and let love) Was Cage Wrong?

You are rating the Worth of pleasure and i say it cannot stick, it is all a personal value system and has no Absolute value. It doesnt matter how many people you can find to agree with you, the value is still relative and not absolute as long as *one person* disagrees. This is very important.

Wrong is wrong.

My original point was a point of order, namely, that there is a problem with black/white characterization of existance. It is a legacy we've inherited and the leaping beyond this way of thinking is very liberating and not a direct criticism of your model of myopia-causation. BUT, I assert that the creature 'hiding' has more control than you suggest. this creature is not a victim of this awful world, it is a co-aggressor as well and has an agenda which only coincides with any model incidentally.

The hopelessness of this paragraph suggsts its flaw; firstly, Nature has no

independent scheme-it accepts all variation. Second, the 'difficulty' of Life is a-priori a facet of Nature and therefore must be considered a *Positive* thing. It must be integrated along with the rest. Looking outside of ourselves is a mistake i think.

Never less than stimulating Elena!

Perhaps. Still I'm very suspicious of going beyond PRIOR to going THERE. After we've investigated everything THERE, if we still don't know enough and aren't satisfied with what we've learned, well only AFTER that would I consider going beyond. Not before, and not instead of. I wouldn't risk passing by the what-really-happened -- what is, as is -- for any later interpretations. No matter where I get if I jump over it, if in order to get there I have to negate the importance of a part of my own life, a part of my own history, I don't care to be there. How do we determine where the important part begins? How do we know, when we ignore our early history and concentrate on our "later self," that we haven't thrown away the baby along with the bathwater? That everything we later look for doesn't amount to just looking for that baby that was accidentally thrown out of the picture?..

Sorry, I didn't realize it sounded a bit harsh. I don't question your qualifications for speaking of course, and I'm most definitely NOT in the attacking mood.

I am quite in agreement with the benefit of remembering every moment of our life, this is a fundamental and powerful and essential thing. I simply wanted to call attention to the use of the term 'True' self. One may get into direct contact with past memories only by being totally open to the emotions that are stored with that memory, and open to the change to one's Ego this will cause. The concept of NO true self can help open that door because it removes the prejudice and the shock. It also is more logical to view the totality of a being as beyond comprehension. Whether religious or philosophical, it is a more comprehensive and effective paradigm than pure materialism.

hello, i-seers

i've been feeling a little gloomy as i read the recent postings about internal images being blurry or clear. I have to confess that i have no internal images in my head at all.

When i close my eyes and look inside, all i see is black. I have read in a few VT books how visualizations are important to recovering vision and i have been following suggestions for the past 4 years, but still no luck. I have good dream memory but can't tell if they are visual or not since i can't recall images.

The best way i can describe my internal view is that it's like an airplane that flies behind a cloud. I know it's there, but i can't see it. If i imagine a house that i lived in as a child, for example, i don't get so much as a vague outline to 'look at', and yet i 'know' what it looks like and could describe it though i don't hear or see it. I also have a lot of trouble recognizing faces, particularly if one aspect has changed, such as dyed hair, or a new beard. And i'm not comfortable when old friends sport new appearances.

Just for the record, i have polled my family - hey, do you all have pictures inside your heads? And everybody did 'cept me. Also, my audio memory is excellent.

My own theory is that, as a child i was surrounded by lots of violence that i usually hid in my room to avoid. I'm guessing that my visual imaginings of the carnage beyond the walls was too frightening to comprehend so i shut down the mechanism. Is this possible? I don't ever remember having pictures inside, but i was born into violence.

Any ideas on reversing this closure? I've been releasing emotional trauma for some time now, so i don't feel that i have any unfinished business there. I keep expecting my visuals to just show up, but so far they haven't. Is there anyone else out there who has successfully recovered their inner vision - blurry or otherwise. And how important is this aspect of vision?

Poor me.

Hello ISEEers,

this is an open question to get some feedback about wearing contacts AND glasses at the same time for different kind of work. The options are:

- 1) Contacts (-1.00, -1.00) for computer work and glasses on top (-1.00, -1.00) for distance work
- 2) Contacts (-2.00, -2.00) for distance work and plus glasses of (+1.00, +1.00) on top for near work

Does anyone prefer one to the other?

thanks
george

I_seers,

Julie said:

>From these clear flashes I get, I gather that my eyes have everything they need structurally to see 20/20. But for some reason, all the factors can't get coordinated except for those brief moments.

I don't think we know what the mechanism is for palming's usefulness.<

I've wondered too about the efficacy of palming, and also of blinking. IMHO palming seems to do two things, relaxing the muscles of the eye and quieting the visual centers of the brain, and secondly it seems to act as a trigger for the eyes to refocus at the moment the eyes are reopened. Blinking seems to me to do only the latter, that is, tell the eyes to refocus. Always after palming, my acuity is best immediately after reopening my eyes. And blinking seems to stimulate the same effect. For example, at night if I awake and attempt to read the LED on my digital clock across the room, if the display is fuzzy a blink or two (or more) will eventually result in a clear image. Any thoughts?

Ted Green

Item Subject: Doubts

Hi Mark,

I will try to answer your questions based on my own experience:

1. I am extremely high myop and have been working on improving my eyesight for past 3 years. I was very sceptical at first. Having no choice (I was loosing my vision at a rapid speed), having an optometrist, who was collapsing under the pressure of not knowing what to do about it, being falsely diagnosed with MS, diabetes (both have failing vision as one of symptoms) and being recommended prescription near to binoculars power by our "optometry specialist", I made a decision. I began with Huxley and progressed through Bates and Dr Kaplan - here in Canada. Although I have not been "cured", I was able to improve my eyesight by almost 7 dioptres. I achieved that by applying the visual therapy (consisting of wide variety of physical and mental exercises) together with relaxation exercises (meditation, tai chi, resting (closing) my eyes after long day in front of a computer for half an hour, etc., etc.) and altered nutrition. I could not afford regular behavioural optometrist sessions, worth \$ 55.- Can. each.

Taking that in consideration, with your low power prescription, you have a marvellous chance to return back to 20/20 vision. In high myopic like myself - I don't think, a complete "cure" is evident for many reasons (i.e. age, power of eye ware and length of time I am wearing it, type of type of work I must continue to financially support my family, personal mental composition and previous life experiences history).

2. Although the term "bad habits" may be an analogy for an instinctive response to a variety of stimulants one meets in life,

whatever the stimulants are, they are real. And it seems to me it all boils down to modifying one's attitude towards life in general. It means to "putting your heart" into your seeing, learning to feel and sense and see rather than "look", it means to want to adopt a new way of seeing - living awareness. That is what it meant for me in order to make the progress, I made. There is vast amount of literature available on the subject. Just yesterday there was a note in this list, containing review of three very inspiring books, some of them I myself have also read and have on my night table for a daily inspiration.

So back to the base of your second question: I think, it depends on an individual if you have to stick with the exercises or if you just stop. In my case, I know I have to continue - I take it as part of my daily hygiene. You - on the other hand - considering your low power - may learn a new seeing habits during your VT and when reaching 20/20 vision, these habits will become "the way of being and seeing". The correct and effective way of using your optical parts of your body will become subconscious. You may not need to continue daily exercises. I don't think, there is a clear answer to this one.

3. The answer to this question probably resides in the unfortunate 20th century epidemy of the "quick fix" syndrome, wanting everything and wanting it yesterday. It also will have something to do with the endangered optical industry and the commercial value, that goes with it.

VT is not a quick fix and it certainly is not a lucrative business. The patient must do it all. Although supplements, good nutrition and behavioural optometrists sessions are definitely a contributing component of the therapy, they will not improve your sight alone. You must want to see yourself - and consequently do something about it - yourself!

I hope, this helps a bit.

Katerina

Hi,

I have some doubts i'd just like to clear up. After reading Huxley's book and Bates' book on 'Natural Vision Therapy' i have obviously become very interested in the possibility of healing my eyesight (-1.75 and -1.5).

It just all seems a tricky thing to believe in. Probably more so here in the UK where very few people have heard of it. I have contacted one vision trainer in London and i asked 'is it possible to return to normal vision?' and i was never given a direct answer. I was told that it depended it i 'believed' or not and whether i would pay a rather hefty hourly fee for personal sessions.

I was hoping someone might be able to help me by answering a couple of questions, such as:

- 1) What clear evidence is there of people permanently returning to 'normal' eyesight? - how many people really are being 'cured' ?
- 2) If the cause of poor eyesight is 'bad habits' then if the eyesight is cured; could you then stop the vision exercises, or should you stick with them?
- 3) Even if NVT works for some people, how come it's not on the front of the headlines on the news? So many millions of people simply think 'bad eyesight? better get some lenses'. Is it really the glasses and contact lens industry which is keeping all this quiet?

I do believe that the suggested exercises work, but i am just really curious to find out how successful NVT is. It doesn't help when most people think you're slightly mad when you mention alternatives to lenses... it's just incredible in this day and age that something like this may (?) work yet it is not recommended by most doctors and eye specialists.

Sorry for being a doubting Thomas...

Thanks for any advice,

Mark Frost

p.s. could you mail me on this number please

> Hi, Katerina,

This helps a lot!! I showed your mail to my daughter, who has -5 at age of 10. She was really inspired by your mail, she did palming before she went to bed and noticed a clear flash lasted longer then before. This morning the first thing she did was eye exercise and palming.

She has read about Bates method. Is this good enough? You went through three books, which one helped you the most? I had trouble finding the book from Huxley from my library.

I've wondered some of the same things. How come when you look at mainstream optometric/ ophthalmological journals, there is almost nothing about reducing myopia with vision therapy? I looked a lot at abstracts on Medline. I think it's done more in foreign countries -- Poland, Russia, Japan. There is a lot on environmental influences on myopia but very little on reducing it once it's there.

And, given all the different people who think minus lenses may be bad for one's vision in some cases, have there ever been studies done, say, of primates wearing lenses in adulthood to see if they get more myopic than primates that don't wear lenses? If not, why not? It's a major public health care issue, surely we can do better than endless experiments with chickens. I would think if an experiment showed that corrective lenses deteriorate the vision of nearsighted primates, it would be pretty convincing that this may happen in people.

Or how about epidemiological studies? Have there ever been studies where the time that people wore glasses was measured over a long period of time, and this was compared to increase in myopia to see if there's a correlation? Couldn't one settle the issue by a few well-done studies?

Wouldn't this be a major health care disaster if massive amounts of myopia are really being created by the optometrists who supposedly are "treating" myopia with lenses?

Is there a big Conspiracy of optometrists *not* to find out if their treatments are harmful?

There is also a subjective effect where wearing glasses may seem to deteriorate one's unaided vision simply by contrast -- one takes off the glasses and things look very blurry by contrast. People get dependent on glasses. Does this just mean they get used to seeing clearly and don't want to see blurrily, or is there really some effect of glasses worsening vision?

My take on it so far is like this:

- Different people may have myopia for different reasons and some people will respond to vision therapy and others won't.
- Vision therapy for many other reasons beside myopia reduction isn't controversial.
- Trying to reduce myopia on your own is often a lot of work and can be very expensive if you get vision therapy -- a lot of people would probably rather just get the surgery. And with plus lenses etc. one may not necessarily be able to get more than a diopter or so improvement -- a lot of people wouldn't think it's worth it.
- I'm sure there is a lot of snake oil involved -- a lot of behavioral optometrists trying to sell expensive therapy to people -- and often, a couple pairs of glasses rather than just one. This doesn't mean behavioral optometry is snake oil in general but it seems open to exploitation -- unscrupulous people selling vague feel-good "cures" that are really just placebos. This may also just be a feature of an emerging field. Behavioral optometrists may also be more careful than other optometrists, and notice things other optometrists don't. It's probably a mixture. One wonders about the optometrists that just work you up with a quick prescription, too. Behavioral optometry is probably a mixture of good stuff and bad.

Supposing you can reduce myopia by doing all close work with plus lenses that are as strong as you can deal with? What is meant by, "is such an effect permanent"? If one makes a habit of doing the close work

with plus lenses, then whatever effect one had would be permanent. If one went back to doing a lot of near focussing, one might get more myopic. One's ongoing life habits influence one's vision.

Does someone myopic who's working on their vision by using undercorrections or plus lenses mean they'll live in blur forever? If they don't ever get to 20/20, are they going to live in blurry vision forever? For a myopic person to see 20/20 they probably need a full correction. If a full correction is believed to be harmful to vision and one were too myopic to be able to get back to 20/20, is blur the alternative to accepting something that may be harmful?

I seem to have fixed about half a diopter of myopia. I wear 1.25 D plus lenses and use my computer terminal about a meter away, so optically it's about .25 D farther than infinity. So I'm practicing seeing at distance whenever I use the computer. When I go around the rest of the time, I don't have any myopia.

>> lens industry which is keeping allthis quiet?

not a conspiracy, just inertia, and glasses *are* much easier. The industry
is certainly not motivated to get everyone to change to helping themselves.

>> I do believe that the suggested exercises work, but i am just really
>> curious to find out how successful NVT is.

I was in this doubtful position too, now i'm way past that as i have
discovered more than i ever imagined--way beyond simple visual acuity :>

>> it's just incredible in this day and age that something like this may
>>(?) work
>> yet it is not recommended by most doctors and eye specialists.

as mentioned, this is not a quick fix, which means work and
patience--everyone fights these battles with varying success. Any
alternative medicine is routinely sniffed at by the establishment MD's. I
find it incredible that in this day and age, chiropracty is still not
covered by many insurance systems. I find it incredible that we are still
invading foreign countries to secure oil supplies. I find it incredible
that people are willing to kill gays, blacks, foreigners, etc. because
they're different. But that's the state of things today--we have made much
progress as a society, still a long way to go.

Examine the feeling of being 'stupid' it's full of good meditation. Doubt

about any plan in life can be fatal to the fulfillment of it, but it cant just be ignored, it must be respected and its roots understood.

I don't see why crystals should be any more dangerous than accupuncture needles. There's several chapters in the book we are going through. I've read the general overview and the chapter on the root chakra and the stones that help that area. The book cautions that if you don't do this right you can make things worse instead of better, but clear quartz crystal seems like a multivitamin or over-the-counter medication, fairly mild and if general instructions are followed, hard to screw up on. I don't remember a thing about electronics but I've run into two electronics teachers on sci.med.vision who may know a bit about how to use crystals to manipulate an energy field. All I know is compressing tourmaline produces a current and there are crystals in watches. The chakra points are referred to as different colors or tones. It sounds like different frequencies of some sort of energy. Using the crystals seems to be like tuning a piano or using a filter to polarize light. I still say that laser surgery sounds like real danger and RK!!!!!!!!!!

>On behalf of a friend (who is treating with a homeopath), do you know of any remedies that have >worked for severe (large enough to sometimes obstruct the vision) with no retinal damage >(tearings, detachments, etc.) floaters? This person has chronic myopia (in the 11 diopter range).

>She is currently on Argent nit. and you are the first the homeo- pathic ophthamologist we have >found.

Dear Mary,

Here are some rubrics you might want to look at in Kent for floaters.

VISION - SPOTS

VISION - SPOTS - floating

VISION - COLORS before the eyes - black - spots - floating (muscae volitantes)

VISION - COLORS before the eyes - black - spots

VISION - COLORS before the eyes - gray - spots

What is the color of the floater?

Any concomitant(existing or occurring with the floaters) symptoms?

What is peculiar about the floater or vision?

What other symptoms developed during the floater?

I would carefully investigate the above questions to determine the right homeopathic remedy.

Arg-n. is often used for floaters. You may want to see if there is any response from this remedy before considering another.

Sincerely, Ed

Yes, but it's even trickier to believe in the standard theory for errors in refraction. e.g. how does the standard theory account for rapid changes in myopia?

<snip>

> 1) What clear evidence is there of people permanently returning to 'normal' eyesight? - how many people really are being 'cured' ?

Not much. This is a chicken and egg problem. Until more people (or another Bates) refine the current methods, we won't get more success and therefore won't get more people encouraged to try it.

> 2) If the cause of poor eyesight is 'bad habits' then if the eyesight is cured; could you then stop the vision exercises, or should you stick with them?

You should be doing "vision exercises" all the time. i.e. using your eyes in a relaxed way.

> 3) Even if NVT works for some people, how come it's not on the front of the headlines on the news? So many millions of people simply think 'bad eyesight? better get some lenses'. Is it really the glasses and contact lens industry which is keeping all this quiet?

I think not. The methods and approaches of Visual Therapy are just not good enough - yet. I read somewhere that Bates thought his methods so obvious and effective that although he had assistants, he didn't bother to pass his methods on formally, so they got muddled. I'm sure we've lost some of the fine details, which may turn out to be

important. e.g. Bates says that shutting the eyes for "... a longer or shorter time..." gives rest, but how long? 10 seconds or 10 minutes?

<snip>

> Sorry for being a doubting Thomas...
Nothing wrong with that.

Peter

I_seers

I had an interesting experience today. In gym class, we were played football. Since i have been doing this VT stuff i decided to try playing without my glasses. I have been prescribed around -7 or so with cylinders, but have chosen not to replace my current lenses which are -5.5 each eye.

I enjoyed playing without my glasses, my eyes felt more alive, it made me feel more energy inside. At the end of the class, i had totally forgotten about my glasses. Not wearing those glasses was fun. It was a new challenge.

Some people say that you should wear reduced lenses and some say that you shouldn't wear glasses at all. I say you should wear reduced lenses when you are doing work indoors. But you should take them off when you do activities outdoors, especially when it is sunny.

I would like to say one thing that i have noticed ever since i have been doing this VT stuff. I don't know if my vision improved, because i only get an eye exam every year, but my eyes in general feel great, they feel alive and energetic. I don't get red

sore itchy eyes anymore. Although i still stare a little.

Since i'm still young (14) i guess i have a little bit of an advantage, but i would advise anyone to spend at least an hour or as much time as they can a day to do some sort of an activity (eg. soccer, football, tennis etc...)""OUTDOORS"" without wearing glasses. You will probably forget for awhile that you even need glasses, and that i think is a good thing.

The only disadvantage i have is that we get a lot of snow here in Edmonton (Canada), which prevents me from doing gym outside without my glasses, but i have decided to do more skiing and skating.

I have even decided to do my Taek won don without glasses now.

I don't see the point in wearing regular glasses or reduced glasses outside at all, except when you could be putting your life or the life of others in danger.

Try it,

Peter

This is great! I was just going to try Arg. Nit.! I was unable to find a source Sunday, but will probably be able to locate it today. And the reason I was drawn to this remedy had nothing to do with vision (homeopathy is so holistic, I have found symptoms that were previously unnoticed disappear along with the once being treated, so this makes sense).

Thanks for the information - it is much appreciated.

I guess I am quite like you, search for better vision seems to become my hobby..I have read all the books I can find in my local library. I did not see a few, they might have been out or misplaced.

I guess I need to be more organized as to what methods to follow. Palming and swing are easy so we have started that. Have your tried the audio tapes by Kaplan?

BTW, my daughter's eyesight has improved a bit after the summer, but her right eye seems to drift a little. She lost her previous glasses and she was wearing a real old glass for the summer. We are now getting her a new pair of bifocals.

I will look up the web site for the books.
Thanks...
Mei-Tien

Thanks for the replies to my 'doubting Thomas' message... hopefully i shall get myself motivated and try some of NVT out... i think my own belief in it is half the problem.

Unfortunately i have recently graduated and have lost my internet account, so i'm just using friend's at the mo. But if anyone knows of success story's in the UK i'd be happy to hear them, and i'll send you details of mine (whatever the outcome)... i should be on this number for the next few weeks...

Thanks again,

Mark Frost

There is not one specific book, that I can single out. I found that combination of different ideas, philosophies - and constant reading and exploring was giving me energy to proceed. I read them all. I found the two books of Dr Robert-Michael Kaplan the most instructive. The first one - used to be called Seeing beyond 20/20 - now it is called - I think - "Seeing without glasses" offers a certain structure to the program. The second book "The Power Behind Your eyes" seems to me building an important "combo" - somehow one book complemented the other.

Dr Liebermans thoughts are also very inspiring.

Different ideas work for different people. A dear friend of mine told me once: "You have a talent to make a hobby out of your misery." Once I heard a successful blind pianist saying: "You must become a bit of a fanatic about things in order to succeed." Both these statements were a confirmation to me that - no matter how you go about it, what you read, whom you listen to - just do it, and do it all and look for the fun and enjoyment in it and put your heart into it. There will come a moment, that you yourself will find the idea, that works for you - out of the vast source of information, available out there for you to choose from. One must find the passion within to go about succeeding in whatever one wants to succeed.

To order these books go to <http://www.sunshine.net/www/0/sn0011/default.html> page - it is a good start.

I wish to your daughter to find the passion and the fun, that goes with it - on the way to improve her eyesight.

Best wishes Katerina

> Hi, Katerina,

This helps a lot!! I showed your mail to my daughter, who has -5 at age of 10. She was really inspired by your mail, she did palming before she went to bed and noticed a clear flash lasted longer then before. This morning the first thing she did was eye exercise and palming.

She has read about Bates method. Is this good enough? You went through three books, which one helped you the most? I had trouble finding the book from Huxley from my library.

Hi there,

I've been reading the list off and on for a few months and thought it was about time that I contributed with my own experience of eyesight improvement.

I'm a twenty-one year old student and I'd been wearing glasses for four or five years with a prescription of -1.25 L and -0.75 R which increased a couple of years later to -1.75 L and -1.25 R. About six months ago I discovered the Bates method and read 'Better Eyesight Without Glasses'. Intrigued, I immediately discarded my glasses, my previous understanding being that it was best to wear my glasses as much as possible to avoid further deterioration. I started palming regularly and consciously trying to avoid strain by blinking often and not 'trying to see' (If it's possible to try to avoid trying to see!)

Well, I didn't actually get my eyes tested during this period but I'm certain thatt they improved a great deal during this period. There were a couple of memorable sunny afternoons where I was able to read signs which required what must have been approaching 20-20 vision. I'm not sure however, whether the improvement was partly psychological since I had such enthusiasm towards improving my sight and believed 100% that I would. (I was certain that within a few months I'd be back to 20-20). I started watching television without the glasses and found little discomfort in doing so.

Unfortunately I did not have the self-discipline required to keep up the exercises and slipped back in to using the glasses (the weaker prescription though). My vision since then has returned to just a little better than it was before I encountered VT, but I'm sure thatt the knowledge which I have gained from the book will help me to avoid further deterioration and perhaps improvement in the future.

I was wondering if anyone on this list has themselves, or knows anyone who, has actually achieved 20-20 vision using these techniques. There seems to re improvement has been made, although I have yet to come across a report of a return to

perfect vision. Also, has anyone had a similar experience to me, where their eyesight has deteriorated once they stopped doing VT.

Well, thanks for listening to me ramble on and congratulations on a very educational mailing list.

Rob.

Could you explain this a little better?

First of all how bad is your myopia?

Second, why are you wearing plus lenses at the computer? Is it to simulate distance vision.. thus reducing strain on your eyes?

Third, how do you calculate what plus lens to wear and what distance to be from the computer ?

I am wearing -4.5 contacts most of the time and seeing about 20/40 with them in. I can work pretty well from the computer at about 1 meter. I am thinking of getting glasses at this reduced prescription so that I can take them off more readily as my eyes tend to feel better with no correction.

thanks

Hello I_seers,

I visited my O.D. yesterday for a progress evaluation, etc and so I'll fill you all in on the results. I feel fortunate to have an open minded O.D. to work with on my VT. He is functioning primarily to document my progress and as a very interested observer.

My last visit was in March of this year. At that time I discarded my contact lens and had two pair of eyeglasses made; one at 20/30 for driving and a second pair at 20/50 for occasional use. The prescription for the 20/30 lenses was R -4.25 -.50x80 and L -3.75 -.50x15. The 20/50 lenses are R -3.50 -.50x80 and L -3.00 -.50x15.

At my examination yesterday the 20/30 lenses were enabling me to read the chart at 20/15 and the 20/50 lenses at 20/30. This represented a reduction of -0.75 diopter in each eye over the last six months. And there was a reduction of the astigmatism in my right eye from -0.50 to -0.25 with a change in axis. There was another interesting (and welcome) change as well. At the time of my March exam I was diagnosed as a glaucoma suspect, with pressures of 21mm and 20mm, and with slight loss of peripheral vision in my right eye. Yesterday the pressures were 19mm and 18mm, and the visual fields test indicated that the peripheral vision in my right eye had been restored to normal. I don't understand how this came about, but I'll take it! A reduction of myopia perhaps? The bulk of the time since March I have gone w/o corrective lenses. I wore the 20/30 lenses only for about one hour a day, and the same or less for the 20/50 lenses. Since the 20/30s now overcorrect and the 20/50s correct to 20/30, I'll stop using the stronger prescription entirely. The bulk of my

VT efforts have simply been focussing exercises involving reading my eye chart, clock face, etc. several times daily. And of course my mental attitude about my vision. And when I work at the computer or read (hours daily) I keep the print at the furthest reasonable distance. Since March that distance has increased from about 10 inches to about 18 inches now. My next appointment will be in March '97 when hopefully there will be more to report. Regards,

Ted Green

There is not one specific book, that I can single out. I found that combination of different ideas, philosophies - and constant reading and exploring was giving me energy to proceed. I read them all. I found the two books of Dr Robert-Michael Kaplan the most instructive. The first one - used to be called Seeing beyond 20/20 - now it is called - I think - "Seeing without glasses" offers a certain structure to the program. The second book "The Power Behind Your eyes" seems to me building an important "combo" - somehow one book complemented the other.

Dr Liebermans thoughts are also very inspiring.

Different ideas work for different people. A dear friend of mine told me once: "You have a talent to make a hobby out of your misery." Once I heard a successful blind pianist saying: "You must become a bit of a fanatic about things in order to succeed." Both these statements were a confirmation to me that - no matter how you go about it, what you read, whom you listen to - just do it, and do it all and look for the fun and enjoyment in it and put your heart into it. There will come a moment, that you yourself will find the idea, that works for you - out of the vast source of information, available out there for you to choose from. One must find the passion within to go about succeeding in whatever one wants to succeed.

To order these books go to <http://www.sunshine.net/www/0/sn0011/default.html> page - it is a good start.

Seers,

I'm in the process of making good on my intentions and exploring what I presently see as the maximum efficiency approach, both for me personally and as a "new paradigm of myopia," the one that has practically forced itself on my understanding. Anyone who is interested in any further developments and in being contacted, please e-mail me your mailing address and/or phone number, since I might not have e-mail capabilities for a while. If possible please do it today -- I'm leaving for LA early tomorrow.

As an update for the newcomers: my starting point 15 months ago was at -8.0D of myopia and about -1.5 of astigmatism. Currently, I'm seeing 20/40 or 20/20 more than half the time, with stability not achieved. Subjectively/emotionally, I'm experiencing this as a spooky crisis of unprecedented magnitude. This about sums up my update for the moment.

Best of luck and maximum clarity to everyone.

Elena

>Could you explain this a little better?

I'm sure Nick will answer, but I can't resist offering my thoughts also...

DISTANCE AND DIOPTERS

Diopters are inverse meters. When you're focussed at infinity, that's normally called zero diopters of accommodation, because $1/\text{infinity}$ is zero. Focussing at 1 meter is 1 Diopter of accommodation, 1/2 meter is 2 Diopters of accommodation, etc.

If you wear a plus 1.25 D lens, that makes your eyes focussed 1.25 D "further" (less accommodation) than whatever you would be at without the lens. So, if you looked at something $1/1.25\text{D}$ (0.8 meters) away while wearing 1.25 D plus lenses, your eyes would have 0 diopters of accommodation, or be focussed at infinity.

VERGENCE (LOOKING INWARD)

All this ignores the

vergence that's going on, where your eyes are each looking inward a bit to see the closer thing. The inward vergence is measured in prism diopters, where 1 prism diopter (or 1[^]) is a 1% slope or 1 cm at 1 meter. You could wear prisms, too, to make the vergence of seeing the 0.8 meter object feel like infinity, too. Some people can't immediately tolerate plus lenses because normally accommodation is linked to vergence, and you're changing that relationship. Same with wearing new minus lenses, of course.

BACK TO NICK

If Nick is looking at something 1 meter away (which would be 1 D of accommodation without lenses), but wearing plus 1.25 D lenses, he's effectively using MINUS 0.25 D of accommodation. I.e., he's "looking beyond infinity."

>First of all how bad is your myopia?

>From Nick's message, I'd say he used to be -0.50 D, but now he's 0.00 D.

>Second, why are you wearing plus lenses at the computer? Is it to
>simulate distance vision.. thus reducing strain on your eyes?

This doesn't apply to Nick, apparently, but:

PRESBYOPIA

As people age, the total range of their accommodation powers diminish. (This is Presbyopia.)

One formula is "your diopters of accommodation possible = 15 - 0.25 times your age." If you're 4 years old, you have 14 D of accommodation. If you're 60 or older, you have zero. (There is only one distance at which you can see clearly.) Many 45+ year olds MUST wear plus lenses to see the screen comfortably, or else keep the screen far away and use big fonts.

People just "entering the Presbyopic age" find more comfort in wearing plus lenses for close work because accommodation gets harder and the lenses make it easier. (My own suspicion is that doing so accelerates presbyopia...)

PRACTICE FAR FOCUS

In Nick's case, I think he's trying to use his focussed work time as an opportunity to also exercise his far focus. My own suspicion is that it's lack of far focus that causes myopia progression, and

NOT the amount of near work. Those chicks that get myopia from lenses get 5% as much myopia with only a 130-minute break each day from the lenses. Vision researchers Frank Schaeffel and Howard Howland propose "that one should attempt to recover precise accommodation to stop myopia progression." (Vision Research 35:1137, 1995) Also, "The authors state that if, for instance, 1 hr of daily distant vision with relaxed accommodation [i.e., focussed at infinity -kip] were sufficient to suppress the development of myopia in humans, concerns about negative lenses augmenting myopia would be relieved."

In Total Vision, optometrist Richard Kavner (1978) says that, when reading, you should look up periodically and focus on a distant small object, and keep doing so until you can see it as clearly as you could before you started reading.

William Bates suggests that kids (and adults) would benefit from a few minutes each day looking at an eye chart at 20 feet and reading the smallest line of type they can. (in Better Eyesight Without Glasses)

>Third, how do you calculate what plus lens to wear and what distance >to be from the computer ?

COMPUTERS AND PLUS LENSES

You pick the distance from the computer so you're comfortable with the size of type, and pick the plus lens based upon the accommodation you want when you look at that distance. (1 divided by distance from screen in meters = plus lenses required so you're focussed at infinity. Add 0.25 D if you want to be like Nick. All of this is RELATIVE to whatever lenses you're normally wearing for distance vision.)

WHERE REAL "REST" IS

Incidentally, the conventional view is that your ciliary muscle (that controls your lens' shape) is relaxed for distance vision and contracted for near vision. I'm not sure what "relaxed" means, but when a normal vision person is asleep or in a dark room, his eyes go to a "tonic level of accommodation" (TA) or "dark focus." This dark focus is usually between 1 and 2 meters. I.e., it's NOT at infinity. The muscles must be stimulated (innervated) to see near, and innervated to see far. Your autonomic nervous system (which controls your focussing) is divided into the sympathetic (active when we are excited) and the parasympathetic (most active when we are at rest or digesting food) nervous systems. There are separate chemicals that nerve endings secrete in each case. Near focus seems to be controlled by parasympathetic, and

far focus by sympathetic. Indeed, far focus can be affected by interfering with sympathetic chemistry in the ciliary (in the eye, anyway).

NEAR/FAR vs NEAR/RELAXED

The point of all this is not to think of eye focus as ON for near and OFF for far, but instead to think of it as TWO different stimuli, and their balance determines your dark focus. With this view, one might suggest that you can improve your myopia NOT by worrying about your near focus/parasympathetic, but by exercising your far focus/sympathetic system. (Note that after you look at something far away, your dark focus is temporarily farther away too (on the order of minutes).)

I.e., those studies which compute "diopter hours" of kids by counting the hours of TV and reading etc., are missing the point. They should be counting the hours (minutes?) of FAR vision!

POSSIBLE WAYS MYOPIA IMPROVES

Incidentally #2, I've never heard of adult eyes getting SHORTER. Unless that does happen, it means that myopia improvement must occur by:

- 1) changing shape of cornea (perhaps by extraocular muscles?);
- 2) rediscovering previously unused far focus (i.e., "relaxing" the ciliary further or stimulating sympathetic more);
- 3) changing the shape of your lens as it grows (and your lens grows throughout your life). There must be some kind of vision feedback to the lens to keep emmetropes (normal vision) seeing well as their lenses grow, it seems;
- 4) Learning to change the shape of the lens with your ciliary muscle. The ciliary has many "processes" (little stubs of muscle) that connect (through suspensory ligaments) to the lens on the front, edge (equator) and back, all the way around the lens. In sci.med.vision, Bill Stacy makes fun of the idea that you have any fine control over your lens ("Ciliary is smooth muscle!"). In my reading, the ciliary seems quite mysterious because it's so hard to study in live humans. It seems there's still latitude for new discoveries here.
- 5) Thickening of the choroid (happens in recovering myopic chicks, unlikely to make more than 1 D improvement in humans, I'd guess.) The choroid is the same stuff as the ciliary and iris, but goes all the way around the eye, between the white sclera and the retina.

6) Changing the pressure of fluids in your eye. The aqueous humor (up front) comes out of the ciliary and flows up front of the iris, where it returns to the bloodstream just in front of the iris. Some people have speculated that too-high pressure causes the eye to lengthen. I doubt it, but perhaps reduced pressure would cause it to shorten, or at least to let the cornea flatten (be less plus).

Good luck with whatever mechanism you believe in, whether it's feelings or primal self or clearing engrams or even ophthalmological science.

> your not palming but rather patching.

Bates actually talked about "one-eyed" palming, especially in conjunction with swinging in the sunlight. He called this "alternate palming and sunning". Again, you are to avoid looking directly at the sun with the open eye; instead, you should blink rapidly while swinging your head back and forth so that the sun is seen to move back and forth across your field of vision.

> But during the process of patching
> an eye, what is happening to the one that is covered ? and the one that
> isn't ?

I found that the patched eye feels much more alive and refreshed when I take off the patch. Its retina recharges, and more. The muscles around the eye also feel refreshed.

As for the unpatched eye, it is free to explore its possibilities without interference from the other eye. All your muscles are interconnected; muscles from one eye are coordinated with the other. Unfortunately, what is needed for one eye may create a bad image in the other eye, and you will be held back in your progress. Once one eye masters its proper movements, the other eye won't get in its way. This is my unproven hypothesis, but one worth testing.

> She also said that you should patch both eyes. Why is that ?

> Shouldn't you just patch your stronger eye to develop your weaker eye ?

This is true in the case of amblyopia, where the light receptors must be made to work -- sensitized. I believe, however, that in the case of myopia and astigmatism, your eyes improve when they are given a rest as well as when they are given the opportunity to exercise. It's like all sports.

Note also that Bates always advised practicing each eye separately. Try this, which always works for me: do your reading at the furthest distance possible (assuming a case of myopia, with or without astigmatism), with one eye only (i.e. patch the other eye), taking your glasses off, or putting on plus lenses if necessary, for a full hour, then take your patch off. If you do this at night, the eye that has been working may actually feel blind by comparison with the newly invigorated formerly patched eye. Remember that while you do this, keep pushing the text back. If it gets blurry, bring it in. If it clears up, push it back.

Bottom line: in patching both eyes will benefit, but for different reasons.

Over the past few years, with practising VT, I often get clear flashes. My left eye is significantly better than my right, and it used to do all the 20/20 seeing for me before I got glasses (in 1983). My prescription was last tested in 1993: -1.75 (left); -2.5 (right, with some astigmatism). My prescription is slightly better than this now, although I've never bothered to have it measured again. What I have found, to my amazement, is that it is often my right (weaker) eye that gets the clearest image during a clear flash. Has anyone else noticed their weaker eye getting the "edge" once in a while?

> > practicing seeing at distance whenever I use the computer. When I go

> > around the rest of the time, I don't have any myopia.

>

> Could you explain this a little better?

OK -- a computer terminal at 1 m away is 1 diopter optically if you aren't wearing lenses.

Diopters measure how much light rays from a source diverge. If you're looking at the moon, it's so far away that the light rays from a

single point on the moon which go into your pupil are almost parallel.

This divergence of the light rays goes as 1/distance of object.

An object a meter away is at 1/1 or 1 diopter optically.

And object 1/3 a meter away is at 3 diopters optically.

If you wear plus lenses, it changes how far away objects are optically.. Plus lenses bend rays inwards. Rays from a close object are diverging when they reach your pupils, and a plus lens bends them back inwards so it's as if the rays were coming from an

object farther away. Wearing +1.25 lenses at a computer terminal that's a meter away actually means that you're asking your eyes to focus at 0.25 diopters beyond infinity. No definite reason to ask my eyes to focus slightly "beyond infinity".

It may help doing this far focussing while doing actual visual work -- just walking around and looking at distant objects may not be asking one's eyes to work at far enough. Our ancestors probably did a lot of active far-focussing, but a lot of us do our real visual work at near.

I have about 1/2 diopter of myopia, and a lot of astigmatism.

> Second, why are you wearing plus lenses at the computer?

I could do it instead while reading a book. It would be necessary to use stronger plus lenses then because computer type is larger than most book type and you can read it farther away.

I've got a little trouble focussing at *near*, so I'm doing near focussing practice by not wearing reading glasses while reading books.

> I am wearing -4.5 contacts most of the time and seeing about 20/40
> with them in. I can work pretty well from the computer at about 1
> meter.

20/40 is about 0.75 diopters short -- your far focus is probably at about 1/0.75 meters, which is farther than the computer terminal. So if you wanted to practice far focussing at the computer terminal, about 0.5 D or more less minus might work better (this all depends on exactly what your 20/20 prescription is). This would be challenging your eyes by asking them to focus 0.25 D or more farther than what they're used to. How much they should be challenged for the best results, I'm not sure. You could try wearing 1 D reading glasses on top of the contacts while working at the computer terminal 1 m away, this would be asking your eyes to focus 0.75 D farther than they're used to. This is the same challenge that 20/40 contacts give you, for distance vision.

Absolutely, Tim! I get more clear flashes on average, from my left eye (which is more myopic by .50D) than my right. They have a tendency to switch hit and reverse, but overall, it seems weird that my weaker eye gets more "bang for the buck" in terms of clear flashes.

Hi all,

I'd just like to know what level of myopia those that are getting clear flashes are at. I'm at about -4.0 and have had one clear flash when I was riding my bike one day and almost rode over a snake! I tell you what I could see that snake as clear as crystal. But that is all and it probably was induced by fear rather than anything to do with my vision improvement.

Al & everyone else,

The way forward for you seems to be clear - Elena's primal therapy sounds frightening enough to do the trick - either that or perhaps a touch of lion training!

(On a more serious note, are you still in e-mail contact, Elena? What do you think to fear as enabling better eye sight? Would you interpret that directly ie as Alistair having suppressed fear at some early stage - or more indirectly such as his mind recognizing that he needed better sight at that time, no matter what originally caused his myopia? Has anyone else had a brief experience such as this?)

I thought I hadn't had any clear flashes either. I'm still not really sure if I do or don't except that sometimes I can count more aerals on the distant building I look at - I guess that means that that is a clear flash (is it??) although I hadn't identified it as such since it doesn't happen like someone switching on a light of anything - and if I didn't count the aerals I wouldn't have known it was even happening.

I wonder if you don't notice clear flashes when you are only slightly myopic (as in my case, -0.25 and -1.0) because the difference between 'normal' and the clear flash isn't that dramatic. (I'd always hoped that a clear flash would present itself as the ability to be able to see each leaf on a tree or something.)

Indeed, consider that the need to see may have caused you to suspend your usual pattern. Have you explored any of the psychological investigations mentioned here or elsewhere? the analysis of motivation and discovering the true sources of your behavioral patterns is essential to gaining those clear flashes-and turning them into continuous clear vision.

Yes I've also found this - yet another surprising thing to happen with my vision, since I've started to look.

My prescription is -4.25 (left) and -3.75 (right) but my left eye has always felt far worse than the right. Although my left eye has experienced fewer flashes than the right one, those that have occurred have been far sharper.

What I do is quickly cover each eye in turn to see which one is "clear". Statistically, my weaker eye gets the higher score, although I can't vouch for the "quality" or clarity of the clear flashes.

I know that I've got one when the symmetry between the two eyes (which are close in diopter value) gets very skewed.

Wish I could nail down how this happens so that I could produce them on demand! Working on it!

I-seers,

Astigmatism confuses me, what is it ?, i don't understand what it means if you have astigmatism. Can you have astigmatism without having nearsightedness or farsightedness ? is it a totally different thing ? If you had myopia and astig. and managed to get rid of your myopia, would you still have astig., and be able to notice it ?

Can someone explain this to me ?

Thanks in advance,

Peter

>
> Astigmatism confuses me, what is it ?, i don't understand what it
>means if you have astigmatism.

Well, if we look in the dictionary we see that astigmatism is defined as "a defect on an optical system (as a lens) in consequence of which rays from a point fail to meet in a focal point resulting in a blurred and imperfect image".

In pure near (or far) sightedness, on the other hand, the rays DO meet in a focal point, as they should. But the problem is that in nearsightedness, this point is in front of the retina, and in farsightedness, this point is (or would be) behind the retina.

The problem is that all eyes, and all lenses, have astigmatism.

Nothing is perfect in this world.

So what does the doctor mean when (s)he says, "you have astigmatism"?

What the doctor means is that you told her/him during the refraction that you "liked" a cylindrical lens.

"Oh really," you say.

You don't remember saying that?

"No, I don't."

Well, remember when the doctor asked you several times,

"Which is better, 1 <click> or 2?"

"Of course."

Well, if you said that a cylindrical lens was better than a spherical lens, or that a stronger cylindrical lens was better than a weaker cylindrical lens, then the doctor understands that to mean that you "like" cylinder, and therefore you have astigmatism.

(The safest thing to say to avoid this is, "I can't see any difference.")

Some doctors, like Bill Stacy on sci.med.vision, say that astigmatism is constant thru life, if you have it today then you will have it until you die, and so they tend to just give you the correction that you say you "like" best during the refraction.

Other doctors, like Paul Harris on sci.med.vision, usually do not correct astigmatism of less than 1 Diopter. Dr. Harris has posted that he believes that if the near or far sightedness is corrected, then the patient's body will correct the astigmatism on its own.

>Can you have astigmatism without having nearsightedness or farsightedness?

Yes you can, but it is rare.

If the doctor says, "You have astigmatism," (s)he usually means that you have astigmatism in addition to near or far sightedness.

>is it a totally different thing?

Well, yes and no. The three vision problems are certainly related, and they are certainly different. Actually they are three specific problems with well understood solutions. A person's actual vision problem is almost certainly far more complex than a simple combination of 2 of them. But the simple combination is the only thing most eye doctors know how to treat! Or diagnose! So that is what they diagnose.

(If the only tool you have is a hammer, all problems look like nails.)

>If you had myopia and astig. and managed to get rid of your myopia, would you still have astig.,

Presumably. But how did you get rid of the myopia?

If with exercises, then the astigmatism would probably be fixed even sooner because of the same exercises.

>and be able to notice it ?

Well, it depends on how much you have, and how closely you look to find it. As I said above, we live in an imperfect world, and astigmatism is the name for an imperfection in a lens or an eye, so every eye has it. Doctors can sometimes detect astigmatism in eyes that have more than 0.125 of cylindrical astigmatism. Actually, the test is so imperfect that they sometimes detect astigmatism in eyes without this much, even though they would not

if their test was perfect.

Bill

No I haven't looked into any of the psychological influences on myopia either here or elsewhere except when it is mentioned in the books I have read on the subject. Stuff like how my myopia started but I tended to skip over those sections and focused more on the exercises etc.

It seems that I do have the ability to see 20/20 but 'my usual pattern' is not to. It's something I need to look into.

Thanks for your input.

Has anyone tried hypnosis in order to improve their vision ?

Consider:

People with multiple personalities have had different eye prescriptions for each personality.

According to Bates, the eye, no matter how bad, is capable of seeing perfectly in a fraction of a second, once perfect relaxation is obtained.

I suppose that is what a clear flash is:

You are relaxing perfectly, and then when you open your eyes, you lose the relaxation (and clear sight) in a fraction of a second. Your brain goes back into its (unconscious) old habit of tensing up, and your vision blurs.

.

These facts (if you believe them.. I do) alone prove (imply?) that our vision problems are problems of the mind, not physical.

Since we cannot seem to easily consciously control our relaxation and thus vision, maybe using a technique to get to the unconscious

anyone tried hypnosis?

could have swifter results.

I've never tried hypnosis .. but many have claimed it works for many problems.

I'm very curious about it and am wondering myself.

Any thoughts?

What about other techniques for getting at the unconcious?

I've used affirmations (for a good reference, read Creative Visualization by Shakti someone or other.. forgot the name) with a lot of success in other areas and ultimately I'm sure it will work for my vision problems as well.

I've tried planting an unconcious command into my mind before going to bed that I would wake up and be able to see more clearly- and sometimes it worked.

I've gained about 1.5 - 2 diopters of my vision back so far in all my efforts, and then the improved seemed to stop. From what I've read here and heard elsewhere, this is a pretty common occurence. People make an initial improvement and then frustratingly seem to hit a brick wall and struggle to make more improvement.

"Struggle" of course is the key word, because the solution is not to struggle.. indeed to not even try. Yet I don't know how to not try because I don't think it is conciously possible. Does to not try mean to not use the concious? That would mean we cannot conciously control the vision and so concious techniques are of limited value. So what about unconcious.. or subconcious methods?

> something.

I was thinking the suggestion would be something like telling the subconscious to release its stress and relax in general. I guess of corse if you trust that the subconscious mind knows what is causing the vision problems, ypu might just tell ut to fix the vision.

>
> By the way, self-hypnosis is also good (and cheap!) but I guess you'd better

thats a good point. Perhaps suggest that I am now ready to release the
pent
up blockage that is causing the myopia ... a very general suggestion
to address
cause of the myopia, not just the symptoms...

Art,

<I suppose that is what a clear flash is:

You are relaxing perfectly, and then when you open your eyes, you lose the relaxation (and clear sight) in a fraction of a second. Your brain goes back into its (unconscious) old habit of tensing up, and your vision blurs.

>

This might have explained what I experienced two days ago. It was amazing. I followed the instructions in Taking off your glasses and See, I actually had my first clear flash!! I was so amazed, but it did not last long and I could not reproduce it later.

For hypnosis, I wonder if the effect can last, it does sound promising.

At 23:27 9/16/96, Art Blake wrote:

>Has anyone tried hypnosis in order to improve their vision ?

not me, but the process does seem to have some potential. I think it's strength would be in opening the mind to those locked away memories, allowing them to be defused. I dont fully understand the process of 'suggestions' placed by an hypnotist, but perhaps in the process of going about in a new 'suggested' trance, one could better see the things that were blocking the relaxed vision and be able to focus effort on removing those things. It is also interesting to consider the model that rather than being put into a trance, that one is actually transforming the *current* trance.

>

>Since we cannot seem to easily conciously control our relaxation

exactly right, making conscious of what is un-conscious is the work. this is one method.

this is self-hypnosis and is very effective at creating new programs. By setting up new patterns, starting with the statement of intent, any new reality can be created.

The premier technique for accessing the unconscious is meditation (aka prayer, yoga). Mantra-repeating a phrase over and over until nothing else exists, Prana-rythmic breathing, Asana-posture, Ritual Magick (invocation/evocation), Tantric practices for ecstatic realization, Dancing, Drumming, even Long-distance Running and Gardening have reported results. All of these techniques essentially silence the conscious thoughts and allow a glimpse of the Divine (Unconscious is synonymous with God). Not to forget counselling/therapy of various and sundry styles from Talking to Screaming to Tarot reading regularly get results.

Story of my life, but that is just more NOISE, every ACTION will have its EFFECT. It's letting the discouragement take hold and stop you that is the real problem.

to TRY to see implies the belief that you cannot, a real catch-22, which suggests that the effort needs to be placed elsewhere. i see clear vision as a by-product of the relaxed and focused state of an actualized being. What can become conscious is all of ones motivations and desires and their conscious resolution (redemption). This mostly consists of discovering the actual source of why one believes or reacts in a particular way as opposed to calling it a 'quirk' or even not being aware of a behavior. There are lots of benefits that come as a by-product of this basic state; general health, good eating habits, quick mind, coordination, 'luck', happy people around you...

Art

The bit about the multiple personalities is a gold mine in terms of the information it gives us.

I've tried hypnosis for other things with good success in some areas. I wanted to try it for vision but got stuck on the exact suggestion, (eg to relax the ciliary muscles?). I guess to "see better" would work just as well because you can certainly trust your body to know how to achieve something.

By the way, self-hypnosis is also good (and cheap!) but I guess you'd better experience it from someone else first.

Bearing in mind Elena's thoughts and discoveries, it may be as well to also provide a suggestion along the lines of not needing to be myopic for self-defense or other reasons and a suggestion that your sub-conscious mind will be able to resolve any previous causes of the myopia satisfactorily in a non-harmful way. I usually tack on bits about being able to trust my body/mind to know what is best for my health and happiness and to achieve what I am asking in the best possible way. (You don't want to take away your myopia and induce chronic asthma as a replacement, if repression of feelings caused the original myopia).

I've heard of "Sybil", but have not read either of those books.
Most of what I know I've read from "The Holographic Universe"
by Michael Talbot.

It's very fascinating, maybe I will check out those books.

Dear I_seers

My experience in behavioural Optometry show me that much more myopic person we think, can use positive at close distance.

In fact, after a little period of visual training with some methods (I use chiefly the S.C.S. Method that I and other two my colleagues have created and experimented), many myopic person must to use positive at close distance, sometimes that the focal lenght show as impossible. many myopic over 2.50 dt. use +0.50 or +0.75 at close distance of 40 Cm.

It seems impossible, but this is usefull for them to maintain the results they have had with the visual-training and is very comfortable. Please, show me your thinking about this argument.

Excuse my very bad writing English and bye bye.

Massimiliano.

Hi.

Actually I read of a case (in an old hypnosis book) about a person who had myopia, caused by "tensed ciliary muscles" - he was able to "cure" the myopia by using self hypnosys to relax the ciliary muscles.... In another case, this person developed myopia (severe) after seeing a bad car accident...she was able to "cure" it by using hypnbosis also....

later...

Hi everyone,

The idea of plus glasses seems great to me, but my experience with them leads me to wonder if there is some other effect that may not be so good. I first tried them about 6 months ago, but gave up fairly soon because I was unsure about the words on my page looking too big and by the need to keep my book absolutely straight, because the smallest angling of the book towards me seemed to produce a magnification effect at the edge of the page.

I'm not sure why all of this was, but I assumed that it may have been because I was using +3D glasses (my eyes were -1.0 and -0.5) and that they were too strong. So.... I decided to try again with only +1D glasses, non-prescription, just labelled 'reading glasses' from a local chemist.

Today seemed like a good day; I had to do a lot of computer work and my eyes felt tired from so much close work. I put the glasses on, expecting to feel the relief I normally feel when I look into the distance - but it doesn't feel the same. Why not?

I feel instinctively as if there is some kind of strain factor associated with plus lenses and I feel a strong urge to try them with just one eye at a time. What makes me feel this? Is there something other than looking into the distance in their effect? Can I ignore the discomfort? My instincts tell me not to.

Here's hoping that someone can shed some light onto the subject; I would hate not to be able to trust what seems to be one of the most useful vision improvement tools.

Caroline made some remarks on the strain she feels wearing plus lenses, especially when using them with two eyes.

This strain comes from the fact that there are two aspects to accurate vision, the focusing (accommodation) and the crossing (convergence). You have trained your muscles to focus for the distance whenever your eyes are uncrossed, and to focus for close whenever your eyes are crossed. Make sense?

Whenever you put on new glasses--or change glasses--you upset this association, and this causes muscular confusion and strain until you adjust to the new pair of glasses. You can learn to adapt, or, you can eliminate the problem by wearing a patch.

When you wear a patch with plus lenses, and you're putting things at your far point, your covered eye is free to uncross itself, and you are more accurately simulating, from the muscular point of view, distant vision. Moreover, some believe that the act of convergence is just as fatiguing, if not more fatiguing than accommodation itself, and by eliminating convergence, you are giving yourself more rest.

I say: if you're finding plus lenses unbearable, try using a patch. Remember to switch the eye the patch goes on on a regular basis. Using the patch may also be tiring, especially if it's forcing your non-dominant eye to do the seeing. But my experience has been that overall, the combination of patch and plus lenses allows me to do close work for indefinite periods of time with absolutely no eyestrain. It is also easier to train to see further and further because there's only one

eye to deal with.

IMPORTANT: I repeat: if you use a patch, don't use it on the same eye every time: alternate on a regular basis! This goes double if you have been diagnosed with cross-eye or lazy eye. When in doubt, see a qualified eyecare consultant.

Shouldn't along with the plus in the lens, we be using prisms? To make whatever we are looking at seem as if it is in the distance so the muscles will relax? I've seen references to prisms but haven't understood clearly how they are used.

One day I may get around to trying hypnosis. I'd also like to find someone who knows about the use of crystals in healing to adjust the human energy field. It makes sense to me that it might work but I only know of one friend in N California who even knew of a crystal healer. It will be easier to find a hypnotist.

A myope who is prescribed for -2.50 D lenses, and has 20/20 vision with those lenses, can see clearly (read letters that are 5 minutes of arc) at 40 cm. That is, her far point is 40 cm. ($100/40\text{cm} = 2.5\text{ D}$)

So, such a person reading at 40cm without glasses is accommodating the same as if she were wearing the glasses and looking far away.

My suggestion (from my 12-Sep-96 note to this list) was that one should practice seeing far, even, as Nick is doing, seeing farther than your far point.

It seems that your idea of wearing +0.50 or +0.75 when reading at this 40cm is exactly the same idea. Your eyes must be focussed FURTHER than your "normal" (prescribed) far point. My personal experience is that if you do this (read slightly further than you think, at first, you can read), then your eyes somehow manage

to focus anyway, and this is good for controlling myopia progression and perhaps good for improving myopia (as it did for me).

This is also the same idea as the "training glasses" that Kaplan and others talk about, where you wear 20/40 (6/12) glasses for normal use.

It may be useful to distribute an "everyday english" version of your SCS Method site (<http://www.webcom.com/visionet/scsing.html>), which covers your techniques for reducing visual fatigue and improving "functional" myopia. It also would be interesting to know if your techniques help adult myopes.

Alex - Thanks for the explanation. I shall restrict my use of plus lenses to be in conjunction with alternate patching (a shame, because I don't feel up to patching at work!).

Incidentally, I spoke to my behavioural optometrist about this and he told me that even +1D glasses were too strong for me (my eyes are -0.25 and -1.0 at the moment). It is a shame that I hadn't had your reply when I spoke to him or else I could have asked about the patching, since he didn't suggest it. He just said that he would recommend no more than +0.5D glasses, if I could find any.

I just thought that other people may like to consider this view, since I often see recommendations for much more myopic people than I am to use plus lenses that are stronger than +0.5D.

One last question - assuming I can't find any +0.5D glasses, do you think that I am safe enough using my +1D ones along with alternate eye patching, in view of what my optometrist said? It sounds ok to me because your explanation of what was causing the strain sounded reasonable.

Caroline

The author of Myopia Myth, Donald Rehm, invented a device called the myopter that used mirrors to produce the same effect. An earlier device caled the tele-opter, which used prisms, was invented in the 1930s by an optometrist. He claimed great results. Some day I will reprint from that article.

I believe, however, that the problem is best solved by occluding (patching) one eye. It will naturally point outward relative to the other eye and you will feel less strain. This is great for reading. Again, I remind you all, if you try this, to let each eye get a chance to work and rest (i.e. alternate the eye the patch goes on, changing, say, once every hour).

Myopes, you will notice amazing results if you do this while reading at your far point, using plus lenses.

Those with high myopic prescriptions can try this by taking off their glasses and reading. It will be much, much easier compared with reading with two eyes without glasses, especially if you have to bring the paper very close to your eyes in order to see clearly.

Remember, keep pushing the text out as it clears up.

WRONG PD?

As Alex suggests, it can be the fact that your eyes are converging as usual for looking at something close, but each eye is focussing far away, and that is "confusing." Another explanation is that the "reading glasses" you got have the wrong pupillary distance (PD). Normally, you measure the distance between your pupils when looking at something far away (normally around 60 mm), and then when you buy glasses, you get the same PD as your eyes have. If you get the wrong PD, it's like looking through prisms, which makes your eyes be more cross-eyed or wall-eyed than they'd normally be for looking at an object. (There's a formula for computing the effective prism: prism diopters = PD error in cm x lens power in diopters, I believe, where whether it's base-in or base-out prism depends upon the sign of the PD error and whether the lenses are plus or minus. One prism diopter = divergence of 1 cm at one meter distance (1% angle).)

MEASURE YOUR PUPILARY DISTANCE

You can measure your PD by having someone hold a ruler up to your eyes while you look at something far away, and measure the distance between the pupil's centers. See Web URL

<http://www.eyeglass.com/Measurements.html>

for "Dr. Welsey's E-Zee Vision" print-at-home PD measuring tool.

I don't know an easy way to measure the PD of a pair of glasses, though I understand it's not hard.

LENS DISTORTIONS

Lens making is very complicated, as there are many distortions that occur, and it's hard (impossible) to eliminate them all. Even the PD idea is only right when you're looking far away (your pupils are closer together when looking close, of course!)

You may also have purchased some "cheap" glasses that have other distortion problems. If you're truly interested in plus lenses, I'd suggest you keep trying pairs every time you see a display of them (presuming that you'll find differing brands and differing PD's) until you find some that give you more comfort. Certainly it's safest to do the +1 D's first, as you're trying to do.

3-D PICTURE VERGENCE

You may have seen the "3 D" pictures that look like a lot of worms or geometric patterns, but if you look at them "just right" you suddenly see a 3-D object appear. In this case, your eyes are NOT converging, but they're each focussing close. Many people have trouble seeing these. It's kind of the opposite problem to wearing plus lenses. I've wondered if people who have troubles seeing those could do better with plus lenses, but haven't found any successes in a few trials!

VR VERGENCE AND ACCOMMODATION

You may also have heard of the problems researchers have with 3-D "immersion" virtual reality. People feel sick/nauseated after using them for a while. Some have speculated it's the lack of variety in the focussing while the vergence does get some variety. Again, a disconnect between vergence and focus. Some researchers have speculated on making different objects require different focussing, as with reality, but it's seemed too hard to do this.

LOOK DOWN TO CONVERGE

You might also notice that if you look "up" (assuming your face is facing straight ahead, and not up or down), your eyes naturally converge less, and if you look down they converge more. I presume this is because usually you're not looking far away when you look down! You might be able to position a book "high" (with respect to the angle of your face) or "low" and find more comfort wearing the plus lenses.

I think your behavioral OD is being overly cautious. I used to wear relative +2.50 D lenses and be able to work at close distance indefinitely with great comfort, similarly to Alex's experience.

I have now moved to even greater power and have started to notice some strain. However, I am not quick to attribute it to reading/computing alone. The stress of my occupation, the rapidly changing conditions, a certain level of anxiety, etc are all factors that I consider. I have noticed that in periods of total, self-forgetting immersion into what I am doing, any strain disappears.

I, too, have noticed that my behavioral optometrist is too cautious. At a recent visit we locked into some not very pleasant negotiation with me wanting more plus and he insisting on less. He initially wanted to even throw cylinder into the lens to correct for my 0.75/0.50 D with-the-rule (the general, benign form) astigmatism. Luckily I was able to talk him out of that. I can now see that he is more motivated by money than helping patients. I got the kind of glasses I want mostly

because they carry higher margin. Cylindrical lenses also carry higher margin (margin=price-cost). He has added pre-PRK evaluations to his practice and as we have discussed here, PRK is a betrayal to VT. Previously he had tried to sell me on that B.S. of Ortho-K. Needless to say I am not happy with the understanding I am getting from my behavioral OD and am looking to change him.

Finally, I think what Alex is saying is key: read at your point of distant clear vision, patch and alternate patching, and push the text away as it gets clear. From a psychological perspective which I also favor I would add: know what you want from life, think of the good/great things yet to happen or to be done, and stay on course.

Yes, Al, but your body was telling you something very important. You can physically see clearly! All you need to do is reproduce the "relaxation" or "circumstances" that happened when you did see that snake whatever that may be.

Let this give you hope! Now, I don't think you have to live in a constant state of panic (this really wouldn't be healthy!), but the exercises and biking may provide more such flashes and when they do, concentrate on how your body and eyes feel. We really do have everything we need to provide the biofeedback mechanism for ourselves with our own bodies if we just are attuned enough to really listen.

Then it is just a matter of reproducing those feelings again.

Hi,

I'm Julie, 36 years old, wife, Mom, web designer and nurse (not practicing, couldn't find a way to do it from home with the five kids! ;-)) , in general, self-made woman. Have had strabismus (crossed eyes) from 8 months old then after operations on both eyes to shorten/lengthen muscles I ended up with a noticable exotropia (my left eye is up and outward). It has become my life's work (well, a small personal part of it~!) to straighten my eyes and, more importantly, to gain central vision in my left eye which at present sees quite well peripherally, but has a central dark spot!

Have been using Bate's exercises and some of my own techniques for years! It was a great revelation when I realized that my left eye wasn't looking directly at an object! Seems so simple, but remember, when I look at something, I don't see it. By looking away from it (slightly left and up) I was using my peripheral vision to try to see well. Now, when I patch my right eye, I practice "spotting" objects as I go about my daily chores (NOT DRIVING!....don't worry everyone...I haven't posted much due to busyness, but have been following that discussion for a while... :-)) I just hope someday that my brain will accept that left, central image and I will then be able to work on fusion.

Anyway it's been great fun and I'd love to hear from anyone who is experiencing a sightless eye (central or otherwise) not just trying to conquer blur (although my right eye is showing signs of needing help in that area!

So, what about that strange Subject: Mary Worth...???? Well, here is one of my exercises that I have found some success with. Somehow, my brain seems to accept the left central image better if I am in dimly lit circumstances.

In a dimly lit room, for some reason it becomes easier to distinguish between light areas and dark areas or the edges of objects. Maybe this is because there is less distraction than when bright lights are seen (or not seen as is the case!). When I look at the edge of a light bulb when it is lit, the fact that I do not see what I should see (an extremely bright light in the center) is very distracting. When I look away from the light and try to see an object, the peripheral vision of the light distracts me from concentrating on the central area where I should see best but only see a dark spot.

Another reason a dimly lit room may provide "better" sight in terms of distinguishing edges is that perhaps the cells that are used for night vision are more sensitive. I am able to distinguish contrasts better in dim light.

I remember as a child of about 10, hearing about the Mary Worth game. It was another of those spooky, ghost games that kids were supposed to try and thereby be terrified. Going into my bathroom one evening, I closed the door and turned off the light. I spun about the obligatory three times (saying, of course, "Mary Worth, Mary Worth, Mary Worth") and looked closely into our full-length mirror on the door. I don't remember what exactly I saw or what I was supposed to see (no Mary Worth...), but I was sufficiently freaked out to hastily open the door and scramble out into the hall.

Now, I play the same game in a dim room looking into a mirror, my right eye covered. It's not Mary Worth I wish to see, but my own left eye looking directly back at itself, registering in my brain.

{{{{{{{{{{oooooeeeeeeeeeeoooooo}}}}}}}}}}}

It's strange when at times I can barely see an eye. When I patch my right eye (the dominant eye which does probably all the central seeing), I still feel that I exist or reside on the right side of my body. In this, I feel my condition is somewhat related to stroke or brain-damage. In order to fully accept the view from my left eye, I believe my brain is going to have to allow itself to "feel" as if I have "moved" into the left side of my body. Talk about becoming a New Person!

Part of the seeing for me has to do with this residence concept. Just where do I exist in my body? I'm not really getting metaphysical here, but talking about a feeling. Somehow I feel as if I am just behind my right eye. If I look at an object, I can mentally draw a line in space which extends from the object through my right eye to "me". When I patch the right eye and look with the left I must consciously tell myself that I am "behind" that looking eye or I feel that I am behind the patch.

It is very interesting going about daily tasks while patching my dominant (right) eye. If I were to drink a glass of water, for instance, I would be just a bit off balance as I put the glass to my lips. I am expecting to put the glass up to the center of my mouth, but with the left eye, the view of the glass is different; I am looking at the glass from the opposite side. I tend to somewhat "miss" my mouth as I try to drink and when I drink, it feels strange.

Doing daily tasks while patching is a great exercise for me. I feel that because it is my brain I am trying to trick into seeing the image from that

left eye, then I must distract my brain by going about my normal chores. I feel that the brain will tend to see more easily if I am giving it a normal scene at which to look and also if movement is involved.

Take care all. And (Elena especially....) Guess when my Mom went back to work full-time and I went to stay with Grandma seeing Mom and Dad only on the weekends! At 8 months age! My Mom remembers my eye starting to turn at about 8 months....."hmmmmmmm".....lest you think this is another "Blame The Mother" clause...I have gotten past that, but it took years. I am ready to see.

I would have to agree with this i use to be able to only see clearly at about 4 inches distance now by doing that mentioned above i can see clearly at 6 inches away, Its no massive improvement but its what keeps me motivated and thats what counts.

Have Fun !

I ended up in the outpatient clinic later that night. I was all of 15 years old, and though I continued doing other things with hypnosis (I became quite adept over the years that followed), myopia remained a no-go zone for me until I gave up hypnosis altogether, 15 years later.

This is fascinating. The "baby mode" method makes a lot of sense to
me. If you can
remember how your eyes functioned when you had good vision, you can
reproduce
that functioning, and regain the vision. Certainly when I was 5 I had
perfect vision.
I didn't get my first pair of glasses till I was 13.

A few questions:

You mentioned that you wore glasses for 18 years. How old were you when you first needed glasses? You mentioned that have now been free of glasses for 6 years. How old are you now? I'm also curious about how quickly you corrected your vision, if you corrected some of it with other techniques (other than the baby-mode technique) How many transition lenses did you need- or did you just forego the lenses completely?

any details would be helpful.

I think my contacts/glasses are slowing down my progress, but I am so dependant on them for driving/working, etc.

Thank you so much.

I was about 9, maybe 10.

> You mentioned that have now been free of glasses for 6 years. How
> old are you now?

I'm 35 now. I stopped wearing glasses at the age of 29, so I just realised, I was wearing glasses for *20* years. Oh boy! Some people get less for murder!

> I'm also curious about how quickly you corrected your vision,

Six years, which is much longer than it would have taken me now, if I had known at the start about Baby Mode. I went through a *lot* of theories, tried and failed at exercises, the works. Baby Mode is the distillation of those 6 years of constant research. The rapid progress I have made in recent weeks toward polishing off the remainder of my visual difficiencies is the basis of the claims, though whenever I accidently went into Baby Mode (without knowing what I was doing) I was getting permanent improvement. Someone starting off using Baby Mode at the beginning would notice very fast progress and would probably think that was the norm.

> if you corrected some of it with other techniques (other than the
> baby-mode technique)

I didn't have enough discipline to realise much gain from the other techniques. Baby Mode doesn't take any discipline... just memory, because you have to keep reminding yourself to go into Baby Mode whenever you realise you aren't seeing clearly.

> How many transition lenses did you need- or did you just forego the
> lenses completely?

I went cold-turkey from day one.

> any details would be helpful.

(See Below)

>
> I think my contacts/glasses are slowing down my progress, but I am so
> dependant on them for driving/working, etc.

I know what you mean. I had two minor accidents along the way to good vision. Now I drive without concern. I see well day and night. You're probably right that they are slowing down your progress, but you have to balance that with your circumstances.

MORE ON BABY MODE

* How can you tell if you're in Baby Mode?

You will know immediately, because when you are in Baby Mode, you will notice an improvement instantly. It may only be slight, but the fact

that it has changed in a positive direction is the indicator. Note how above I said that when I remind myself to get back into Baby Mode, my vision clears up immediately... that's the clinical indicator.

* What about Clear Flashes? How does Baby Mode relate to these moments? Baby Mode may or may not induce a Clear Flash every time you go into it, but overall, you will see more Clear Flashes the more you stay in Baby Mode. A Clear Flash is an inadvertant jump into perfect Baby Mode. Baby Mode is a conscious thing you practice till it becomes the unconscious norm. Clear Flashes begin to come more frequently, and last longer.

* How do I induce Baby Mode consciously?

First, by remembering its characteristics from your past, then by putting your eyes *back into the past*. When I first started doing it, I used to remember my childhood, and the innocent way in which I looked at the world as if it were brand new and made just for me.

When I began practicing Baby Mode (the discovery of which was inevitable once I worked out the Stress Model) I started seeing things again that I saw every day as if it was the first time that I had ever observed them. I was startled! Colours became brighter, things got "rounder" and fuller, and lo and behold, sharper! Anything that attracted my attention got it, only I found I wasn't staring at things so intently as I would have before.

But then I would suddenly realise that I was seeing clearly and my *focus* shifted from what my eyes were seeing to what was going on with my eyes. I fell out of Baby Mode and the clouds came over again. No problems... I knew I was onto a good thing. I just slipped back in again, without sweating it, and the same effect occurred again and again.

* Are there any other characteristics of "Baby" vision I should know about?

Yes. Children do not constantly check their vision to see if they are seeing clearly. This is something that myopes tend to do obsessively. It is typical in fact for a child to have a vision problem for weeks before it is picked up, and comes as something of a surprise to them. This is because they give seeing *no attention at all*. It is just something they do automatically. Its like the situation where most healthy people are not aware of their heart beating, except when it is brought to their attention. A heart patient on the other hand is aware of little else. One can say that even with 20/20 vision, a recovered myope is not cured until seeing no longer absorbs any of their conscious attention. I am almost at that stage after practising Baby Mode. When I've reached it, I'll probably write down everything I know about correcting myopia naturally and then dissappear off the scene, back into the normal world!

So, I hope this helps. I would love to hear about people's experiences in using Baby Mode.

Anyone can practice Baby Mode, since I have published this on the Net, but if you would like to begin a more or less formal trial, I would be more than happy to help. The results of a formal trial would be invaluable for helping others to follow the same path to improvement. I am planning to write a book about my method, and your experiences will definitely constitute a contribution to the effort.

I will personally respond to anyone writing to me directly by email. Please allow 7 days, since I regularly get quite a load!

Very best regards,

Linda Wright

-

Dear vision specialists,

In the beggining, I apologize for my bad English ...

We have a daughter who is in a very bad situation. She is 10 years old with a very high degree of myopia. She also has and astigmatism. Her myopia grows about 2 diopters ----- per year. The doctor also told us that the vitreous of her eyes is not so ----- clear.

I tell you some details about her prescriptions:

She was born on June of 86.

She weared glasses for first time on September 92 with the prescription:

RIGHT: SPH=-3.75, CYL=-1.50, AX=160

LEFT: SPH=4.00 , CYL=-2.00, AX=20

On May 94

measured by the doctor (with machine):

RIGHT: SPH=-6.75, CYL=-1.75, AX=163

LEFT: SPH=-7.50, CYL=-1.75, AX=24

wearred glasses:

RIGHT: SPH=-4.50, CYL=-1.75, AX= 165

LEFT: SPH=-4.50, CYL=-2.00, AX= 25

On June 95

measured by the doctor (with machine):

RIGHT: SPH=-8.75, CYL=-1.75, AX=160

LEFT: SPH=-9.50, CYL=-2.00, AX=20
wearing glasses:
RIGHT: SPH=-6.50, CYL=-1.75, AX=160
LEFT: SPH=-7.00, CYL=-2.00, AX=20

On January 96
measured by the doctor (with machine):
RIGHT: SPH=-9.75, CYL=-1.25, AX=165
LEFT: SPH=-10.50, CYL=-2.00, AX=20
She didn't change glasses

On September 96 (now)
measured by the doctor (with machine):
RIGHT: SPH=-10.50, CYL=-2.00, AX=170
LEFT : SPH=-11.75, CYL=-2.00, AX=10
she is going to wear glasses:
RIGHT: SPH=-9.00 ,CYL=-1.00, AX=180
LEFT: SPH=-10.50, CYL=-1.00, AX=180

As you understand, we are very desperate from this situation.
Here in Greece, the ophthalmologists don't know the behavioral optometry,
the orthokeratology or other alternative methods. So there is nothing that
they can do to stop the progress of myopia.
I think to fit her with hard contacts (RGP). What do you think about it?
Any answers for our problem would be greatly appreciated.
Do you believe that would be better if i take my daughter in the US (in NY is
more easier for me)? Is it possible a visit to some specialist there to be
usefull for her?
If you prefer, you could answer in my personal address:
iapetos@matrix.kapatel.gr

Thanks in advance for your help.

Well it seems that the best way to improve your vision is to learn how to relax your eyes! Stress and tension are the enemy! Of course imagine how many other organs in the body are affected as well!

I was thinking about this the other day and decided to write a list of all the known ways of inducing relaxation that I could think of:

- exercise
- eating right & staying off drugs
- humor
- fun, joy
- sex
- meditation/yoga
- love
- massage
- breathing properly

Can anyone else think of anything to add?

Interestingly I have been thinking about the same thing recently, only focusing more on the period close to when I got my first pair of glasses (at 10). I was trying to recreate the 7-8th years of my life. I would take off my glasses and hold them in my hand as I walk from the parking lot to work or wherever and look around at buildings, signs, trees, etc trying to remember how I used to see as a young child. The biggest problem, and the one that may spell doom on the whole effort - **I do not remember how I used to see as a child**. I **know** I could see perfectly but I can't vividly remember how it **felt** to see like that. My earliest memories date to when I was 8 months old but again, vision is not part of the memory. Maybe exactly because I didn't pay any attention to the way I saw. My earliest vision-related memory is from the age of 10-11 when I was once testing my eyesight by reading a newspaper at armslength, something I can't do now bare-eyed.

I doubt I'll be able to revive any hidden early memories. As our perception is selective, our memories do not hold every aspect of our or the universal existence, except thru the oneness or everything is in everything paradigm. I see the process more as a travelling back and getting to know oneself better. I am not pouring cold water on the 'baby vision' technique but in attempt to be truthful to what I think is cool-headedness I don't see a way back to complete innocence once sin is known. It is the sinful recreation of innocence, the innocence lost by virtue of our (and matter's) very existence, and I revel in this sinful innocence.

At 17:22 9/22/96, L. Wright outlined the 'Baby-Mode':

Very well-stated Linda, thanks. I have zoned in on this also and have been getting close to complete independence (i go several days without wearing glasses now, only in occasional situations do i decide to don them). Your statement of observing with genuine curiosity and interest, (open-minded and non-prejudicial i would also say, certainly another 'skill' a typical child has), is the secret that made all the difference for me.

Could you expand on what types of things spurred your recollection of this Child-Self? The art of remembering is very much like the art of seeing so rather a conundrum!

How about:

Yawning

Napping (and otherwise getting enough rest)

Juggling (easier to learn than you might think)

Petting dogs, cats, birds, hamsters, etc.

Hugging willing people

Dancing, singing, making music

Playing catch (a lot more fun than I remembered it being!)

Taking long showers (or soaking in a warm bath)

Drawing, painting, sculpting, building

Yard work, gardening

Waving at people and smiling (after a few times they usually wave back :)

I seem to have run out, but I'll bet there are more! Great idea to list them.

Mary

i would state this as 'stress and tension are the signals of unfulfillment' in order to highlight the thing i see as crucial; that limiting or restricting oneself in one way or another sets up the dissonance and ungrounded energy called stress.

Kip

Many thanks for the wealth of things you gave me to think about.

I think you could be right about the wrong PD because my face is narrow (I always have microscope eyepieces or binocular eyepieces set much closer together than other people seem to do). I'm going to have a look at the web site that you mention.

I have seen the 3D pictures and I have no problem looking at them (even turning pages of a book without 'losing' the focus) - however, I feel that I focus further 'through' the picture, rather than close to. (I know that there is supposed to be a way of seeing the picture "inside out" and I had thought that that was by focusing closer rather than further away). (I had previously wondered if these 3D pictures would be good exercise for myopic people, by teaching them to focus 'through' something and hence relaxing the eyes a bit).

The tip about raising or lowering the book seemed very useful; I shall try that and see how I get on.

Thanks again,
Caroline

Baby Mode.

I think I naturally went into baby mode when I first started vision therapy. The world looked so fresh and new that I was responding like a child. The light felt like it was dancing over everything and the colors were so vibrant and alive also my depth perception was heightened. Then I think I let it all slip.

I am excited by this concept because I instantly could see and feel a difference. Baby mode isn't so much relaxing as it is seeing in a more aware and alive way. I think I was getting more passive and lazy about my vision and I wasn't seeing as much improvement.

Thank you for this baby mode post you've given me the kick in the pants I have been looking for to help keep me going with this vision quest.

Best of luck to all
alexandra

Thanks the notes on Baby Mode vision. A few months ago, I focussed on letting my visual perception regress to a pre-glasses stage while in a meditative state. The results were very promising: I noticed improved clarity (though not 20/20) as soon as I opened my eyes. After a while I stopped for three reasons. First, I have been trying out a lot of techniques and that was one among many. Second, I wanted to work on emotional issues related to childhood experiences and wanted to concentrate on a later period. I am just now realizing that it was unnecessary for me to correlate so closely the regression meditation and a review of childhood experiences. Finally, recent personal changes have disrupted the continuity of some of my endeavors. I'll work on it some more though, especially after those excellent suggestions.

dear i-seers:

i've been doing exercises for presybiopis and a slight astigmatism in my right eye. as i reported a few months back i felt that there was major improvement making both conditions nearly neglible. but something curios has been happening.

my left eye is both dominant and i think, not into the presbyopia in the first place. i need to hold any sort of reading material nearly twice as far away with my right eye (the astigmatic one) than my left. (btw, i'm now convinced after exercises and whatnot that my original examination where i got the bums' rush to get reading glasses, was very inexact since it read that i was evenly sighted in both eyes.) To see comfortable with my right eye only, for instance, i have to hold print (approximatealy 10-12pts high) about 12" away but can see it clearly at 6" away with my left only.

the exercises i have been doing have been for both eyes and until recently i thought everything was great. much more visual comfort when reading and less strain. and no need for reading glasses and little difficulty/discomfort from the astigmatism. i think that the exercise helped make the astigmatism nearly neglible except that i've noticed that it "kicks in" when my sinuses and my hormones are flaring. I've also noticed the astigmatism become more problematic when i'm near a chemical smell (i recently have gone into several stores that sell carpeting and linoleum) and when i'm tired. (btw, accupressure points on the face remove the astigmatic problem immediately but the results don't seem to be long lasting.)

my difficulty now, so it seems, stems from the difference in visual

capabilities between my left and right eye. i have been occassionally patching my left eye to give my right eye a chance to 'catch up.' i would like to ask the group, and Dr.Kaplan if he's reading the posts, several questions. could it be that the exercises have elminated the need for reading glasses (which i bought and never used) but have shown up the difference between my two eyes all the more? and more importantly, in terms of behavioral work: i feel that i could continue the exercise i was doing as a general anti-presbyopic therapy but now patch my left (stronger visioned eye) and just work the right eye. What would anyone recommend or amend to that? Also, if there are behavioral exercises that anyone can recommend for my weaker (right, astigmatic eye) please let me know. Thanks in advance.

Months ago, it might have been when I first signed on to the group, Dr. Kaplan suggested pin-hole glasses. Well, they sound interesting. Yet my concern, and i feel my present visual discomfort, comes from the disparity of vision between left and right. The pinhole glasses sound like a very democratic use of vision and I want to even things up a bit before that route - if my idea of working the right eye is correct in the first place.

also, would any of the Bates methods for distance improving help with presbyopia? I spent some time yesterday reading his eye chart up close with my left eye patched. of course the letters were too big but the black did feel soothing. (i don't know if it's relevant, but my distance vision was 20/20 when last measured.) i mention the bates chart because the other difference in quality of vision that i notice with my right eye is that print does not appear as dark (or black) as it does with my left. the left eye seems to see more clearly (sharper images) and a deeper sense of hue. could it be my left-handed, left brained, lefty politics has corrupted my right eye?

Thanks again to all responses.

As far as relaxation goes, I'd like to add:

body surfing,
cooking
tennis
e-mailing
art in all it's varieties
journal writing

I can attest to this as my early experiments with mystical trances caused a crisis which almost landed me in a mental hospital. I was 18 and couldnt remember my own name nor could be certain about anything. Very scary situation which took me several years to calm down over, (it still gives me the creeps) i was 18 and just went too fast without experienced guidance.

Nevertheless, i dont think the kind of breakthroughs that we discuss here are possible without some major shakeups. Foundation beliefs come into question and get deposed. The myth of the Pheonix comes to mind. With patience and courage, anything can be handled i believe.

>>

I agree, but these accelerated methods can quickly dispell much doubt and

confusion as to the real nature of the change. If done with reasonable safeguards, it could save one a lifetime or two. Would you not say that your success has that as a factor? mine sure does.

BTW, i forgot to congratulate you on your success, this is the most incredible vision story i've ever heard and is *extremely* encouraging.

Hello,

I printed the astigmatism mirror at my office and started experimenting there. I see the vertical lines sharper and darker than the horizontal lines. Does this mean I am an atypical astigmatist? (and what does vertical compared with horizontal mean?). When I put my glasses on, it seems I'm a typical astigmatist, as if my glasses overcompensate. I must say that I am experimenting to leave my glasses off. Some 2 months ago, I went down from -1.75 myopia to -1.0 and went to an ophthalmologist and bought new glasses.

I'm going to an optometrist at the moment and am at -0.75.
(The amelioration is due to a relaxation therapy I followed some six months ago)

Strange enough, when I try the astigmatism mirror in my kitchen at home, I am **NOT** an astigmatist. When I put music on, this can change. This is probably in support of the thesis "astigmatism=tension"(*), or could it change with distance (30cm - 1.5meters) between eye and mirror? What I ask myself is if focus (like in photography) could play a role in "seeing" astigmatism or not.

Regards,
Marc

I haven't even finished this article yet but thought you all might be interested in knowing that the latest Yoga Journal (Oct 96) has a good article on Tibetan Medicine that touches on myopia. Per author Kate Roddick "Precious Pills" have been known to cure severe short-sightedness. These are prepared only at the Medical Institute in Dharamsala, the Kunphen Clinic in Kathmandu and the Medical Institute in Lhasa. They are named for their ingredients, which include precious gems and minerals, as well as for their superb healing powers. The author says she witnessed a cure of severe shortsightedness.

To me these clear flashes are like a flashlight with a connection loose. you shake it and the light flashes on then off. Just a little loose connection.

Maybe those primitive Tibetans know something we don't. Next time I'm in Nepal, I'll try and get some of these and I'll let you all know what happens.

I_seers,

All this talk about baby mode has caused my to look back into my life when i was a baby, right now i am only a teenager so it is not that far back. Still, memories that i have, are few and strange. So i decided to look at some baby pictures, which instantly brought back some more memories. I noticed a few things that i find interesting.

As a baby, less then 5 months, my eyes where always wide open, looking at things all around me. So far that's pretty normal.

I noticed one picture of when i was outside in the sun with my brother, my forehead had a big frown and my eyes were squinted. I believe that this might have something to do with why i have a severe case of myopia now. Aswell as why my pupils are generally bigger then other peoples pupils in the same lighting condition. My pupils are usually huge, even in the sun. Does anyone know of any ways i could make them get "smaller" ?

I have decided to do more sunning which i hope will reduce the size of the pupil. Aswell as the facial exercises found in Janet Goodrich's book, Natural_vision_improvement_ in chapter 4, to get rid of that awful frown.

I had difficulties remembering my baby years, and would suggest for anyone who has difficulty as well to look at their baby and childhood pictures, and look for things (physical + emmotional) that may have caused you to develop your vision problems.

Any comments ?

Have Fun

-Peter

I_seers,

I notice that a lot myopes who have a mild case myopia are frustrated with the fact that they can't improve their vision. And after seeing all the high myopes bring their myopia down a few diopter rather quickly wonder why they can't aswell.

Correct me if i'm wrong, but someone who has 20/20 vision can see a 20 size letter at 20 feet, Right.

20 feet = 609.6 cm

Someone who needs -0.25 lenses to see 20/20 can only see really 13 feet (or 400 cm) away. Right.

Think of it as a ladder, as you go down more and more the difference between the diopter level that you can see decreases.

e.g the diference of what you can see at :

-1.00	100 cm
-2.00	- 50 cm

	is: 50 cm

Compared to:

the diffrence of what you can see at :	-7.00	14.3 cm
	-8.00	- 12.5 cm

		is: 1.8 cm

So when you climb up the ladder the amount of time it takes you to improve keeps taking longer, usually. But that just means that you have to be more and more patient. Hey VT isn't just good for your eyes it's also good for your character :-)

Please correct me if i'm wrong, I would appreciate it,

-Peter

DIOPTERS, NOT DISTANCE

It's true that modest myopes have a larger DISTANCE change from a fixed diopter improvement than worse myopes would have, but I don't see why this means it's any harder. I think of diopters as being "how you measure accommodation" (perhaps having been brainwashed by reading literature). Your eye and many lens configurations do as much work to move one diopter in any range. It's similar work, for a normal vision person, to move from -2 D to -3 D as it is -5 D to -6 D. (In fact, it might seem harder to do -5 to -6 because there's already some strain.)

BENT WIRE ANALOGY

Here's an alternative idea of why it's harder for mild myopes to improve (I can't back this up with any research, it's just idle speculation.):

If you have a bent wire, you can't straighten it out merely

by making it straight. You have to bend it "too far" in the opposite direction so that when you let go, the wire springs back to being straight. Anybody who's tried to make a coat-hanger wire be straight has experienced this.

However, a large bend can be reduced quite a bit by simply pulling on the ends of the wire, or making it lie straight on a table. You can't eliminate it, though (at least with your hands and coathanger wire) this way.

UNBENDING YOUR EYES

Mild myopes are like slightly-bent wire. Going without glasses is like pulling the wire or straightening it on a table. You can't straighten it. To fix it, you need to bend it "too far" in the opposite direction: wear plus lenses while looking far away, often and long enough so that the eyes "spring back" to normal vision when the lenses are removed.

The same idea applies to anything that "springs back". Bend it far enough, and it won't go back to the same state.

More severe myopes can do a lot of "straightening" simply by going without glasses or wearing weaker lenses for whatever distance they're working. A good starting point might be Nick's +0.25 D "beyond infinity".

In other words, strong myopes might improve anytime they take their glasses off, but weaker myopes need plus lenses.

ORTHOKERATOLOGY/CORNEAPLASTY

Incidentally, all this is analogous to orthokeratology, where they put lenses on your cornea with the intention of bending your cornea 'too far' so it springs back to normal vision when the lens is removed. The trouble is that gradually your cornea returns to its previous state, and you're myopic again. Lately, there are chemicals to add to your eye to make the cornea more bendable, and when the lens is taken off and the chemicals dissipate, the cornea sticks in the clear-vision state (corneaplasty - see URL <http://www.slackinc.com/eye/pcon/199606/cornea.htm>). This is much more promising, to me, than the laser treatments because it's likely repeatable (you can change your prescription later) and it doesn't

remove or cut any tissue.

ANECDOTAL VT

Since we don't know (at least, I don't know) what the mechanism is for VT adult myope improvement, it's hard to say what's really going on or why it's harder, or even what the best strategy is for improving, other than "gee, this worked for me, it should work for you too!"

I'd love to see a collection of myopes who wish to improve, then do various eye measurements (ultrasound measurements of lens position, eye length, and corneal shape, as well as the usual acuity and 'best lens for clearest vision' tests), and then set that group off on improvement. Later, repeat the tests, and see what changed in the improved myopes. Does anyone know of a study that did this?

Julie:

In Spain we have some difficult time getting the Yoga Journal. I would be very happy if you or someone on the list, could get me a copy of this article, or the whole magazine. Of course i am willing to cover all expenses related with it.

My personal experience with VT has about 10 years of different therapies:

- a little happy with acupunture & homeophathy
 - + very happy with massage. (neck, back, around the eyes)
 - + happy with the 'accomotrack' ciliar muscles exercises, although somewhat expensive, due to the number of sessions needed for some results.
 - + sun baths, exercise or games in the sun, freesbee, tennis, ping-pong
- I would recomend.

In these years I have come from 6 diopter down to 2, and over all i am very happy with VT - i must admit i am not very persistent with the exercises. I can skip them for 2 , 3 or more months.

but also I have to say that VT exercises relaxes all my body & mind.

Best regards from SPAIN.

Hello Bill!

Sorry about the delay in getting back to you. I've been swamped, and I've changed ISP's. Please note the new address.

What sparked the recollection of the child-self? I suppose it was just a realisation I had. I can remember when I got it... I was struggling to remind myself to do all of the things on my list of better vision habits, when it suddenly occurred to me that I used to do it naturally. Since I have a good memory, and a lot of experience with regression, I just *did it*, and I got *instant* results. It was the first time I'd ever been able to improve my vision under conscious control. I knew I'd struck gold!

Please find enclosed the latest description of my method. Feel free to practice it and circulate it amongst your friends. Start your own grass

roots revolution! And please let me know of your successes.

Very best regards,

Linda Wright

THE WRIGHT METHOD - AN ALTERNATIVE APPROACH TO CORRECTING MYOPIA

Briefly, I wore glasses for almost 20 years, and I have had some remarkable improvement by using the techniques I will describe below. Other programs exist, but I never had much success with them because they were too complex, involving too much discipline. The way I have finally found involves more a gentle change of lifestyle and seeing habits, and seems to get better results.

The Alternative Approach to Myopia is based on the principle that the body, given half a chance will heal itself. This is a fact. It applies to every part of the body, including the brain, as is now being discovered. Why should the eyes be any different?

When you begin to experience this for yourself, you will find that your initial improvement comes as very brief moments of sudden crystal clarity. These moments are called Clear Flashes, and if you have already experienced them then I am speaking to the converted!

Over time, these moments will become more and more frequent, and they will last for longer and longer periods. They will then begin to predominate, until you are seeing very well most of the time. You will still have situations when you can't see quite as well, such as at night, or in dim light, but even that will start to improve.

I am now in the night/dim light phase. I see perfectly out of doors, and now am beginning to see perfectly inside. This would have been impossible for me even a year ago, when I really didn't know *why* my vision was improving... just that it was. Now that I have gotten to the bottom of the Stress Model, I am polishing off the last deficiencies.

But five years ago, I couldn't read the lines in my own palm more than 6 inches away from my face. Today, I do everything without glasses, contacts or squinting. Tomorrow, my vision will be restored to what it was when I was a child, before it was so casually wrecked by slapping crutches on my face.

Here is my story;

When I was 9 years old, it was discovered that I needed glasses. Whether I actually did or not is a subject of some dispute with me, because as I will explain, what I probably needed more was a break from the stress that had temporarily overwhelmed me and my little world.

It began as boredom in school, and was exaserbated by a personality conflict with a teacher who probably disliked me almost as much as I did her. For some reason, she could not see that my rambunctious behaviour was my reaction to the things that were bothering me. My homelife was in a turmoil, another child (my sister) was on the way and my mother was ill. I wasn't coping well, and the class was going too slow for me. I read voraciously to stimulate my mind and escape, and even began reading in the dark under the covers by flashlight. I was a case of lifelong myopia in the making.

My teacher had been writing notes on the board for us to copy for the tenth day straight, and I had had enough. I put my pen down and refused to work. She noted this and became angry. I was headed for trouble and I knew it. When she confronted me, she offered me an out; "Can you see that?" she asked, pointing to her boardwork. I said, "no." She immediately wrote a note to my parents to tell them I needed glasses. By accepting that excuse, I was spared a serious punishment, or so I believed!

Having painted myself into a corner, when I was taken to the eye doctor by my folks, I was anxious to fail my test, because then I would not get into trouble. Now I have to say that failing the eye test was not hard, because I did have a bit of a problem seeing because I was genuinely stressed. But at the time I knew exactly what was wrong, and that I didn't really need glasses even though I did have some slight blurring. I just needed someone to realise that the class was going too slow for me and that I wasn't happy in school.

I got my glasses, and my father insisted that I wear them constantly. I kept trying to go without them (as many mildly myopic children in the same situation so often do). But it was no good. I got in trouble every time my parents caught me without them on, and within two weeks I had a *real* problem. My eyes were wrecked.

Now I see how I contributed to my own problem, but only after having considered the events of that time over almost 20 long years. At age 9, I didn't have the wisdom or the strength of resolve to stand up for myself and say what was really troubling me. The emotional stress I was going through was real however. In relative terms, an adult in the same situation might have turned to drink or drugs. But enough about that.

I never lost the conviction that wearing glasses was wrong. But I was trapped, and for the rest of my childhood I had to pay for my one moment of weakness. I won't bore you with the details of how bad it is to grow up wearing glasses, because surely you already know what it's like.

But the damage was more than just cosmetic or emotional. At age 16 (after only 7 years of wearing glasses) I received a blow to the head which resulted in a torn retina and surgery. Myopia was doing me damage far greater than what I could have imagined. The surgery was successful, but the risk was always there of further injury. I had floaters and white spot flashes, both classic evidences of myopic atrophy of the eye. I got scared.

By age 29 though, I was more or less reconciled to the idea that there was no solution, and that this was my "cross" in life. The news that surgery might fix my nearsightedness excited me only briefly, since I had already had one operation and didn't look forward to another. I always longed for a cure though. I never gave up hope.

I tried contacts for a while, because over the years, my perscription was getting stronger and stronger. Unfortunately I don't remember what it was, but my eye doctors looked grim whenever I asked them if things were getting better. I suppose I really didn't want to know. In talking to ophthamologists since, we've worked out that it was probably about -10 to -12 diopters at its worst. Very bad.

Then, shortly before my 30th birthday, I had a lucky accident. I broke my glasses, for the umpteenth time, but this time, it was over a holiday weekend, and there was nothing I could do. My contacts were not in any state to be used as a substitute. I was in trouble, or so I thought at the time.

I was virtually blind without my glasses. I couldn't see clearly more than a few inches in front of my face. How was I going to make it through the weekend?

I was afraid of getting hit by a car, or falling down stairs.

Wandering around the streets, trying to keep from getting hurt, I ended up playing safe by going into a fast food restaraunt. I was feeling very sorry for myself. Munching on my burger, I happened to glance across the street. I read a sign for a sale, then went back to staring at my food. All of a sudden, it hit me; I shouldn't have been able to read that!

I looked back up at the sign, but once again it was just a big orange blur. Too late though, I had caught my eyes in the act of focusing!

I was shocked! There had been a brief improvement, and contrary to the orthodoxy that I had been taught, this shouldn't have happened!

I had discovered quite by accident that my vision was not set in cement, but that it *varied* slightly from hour to hour. A slight variation, to be sure, from extremely disfunctional to very definitely disfunctional! But it had changed.

The fact that it *changed* was the point. Until that time, I didn't believe

it could. Right then I swore off glasses for life, and decided I wouldn't replace the pair I had broken. I went home and I threw out my old contacts and everything that reminded me that I had once worn glasses, save one photograph, which I kept for other reasons. Since that day, I have never put another pair of glasses on my face, and never will.

It wasn't easy going cold turkey. I believed that my vision would improve naturally, out of the influence of my glasses, which I had suspected since childhood had been the cause of my problems all along.

In the time that followed, I realised that my eyesight wasn't going to improve in a week or two. I honestly didn't know why it should take so long, but I tried to find out. It was a slow process of discovery, discarding one wrong idea after another, until I finally had the whole picture of what was holding up the show. Eventually I discovered some basic principles that I will share with you;

- 1) Ordinary Myopia is caused by stress, and stress is the main factor inhibiting its improvement.

Not only emotional stress, but environmental stress. Bad seeing habits like squinting, reading in bad light etc. Wearing glasses of the wrong perscription. This and almost any number of like things can contribute. All of these things, as well as childhood emotional trauma played a part in my myopia, beginning at about age 9. And even after I stopped wearing glasses, in my ignorance I was continuing to generate stress by being anxious to see clearly again. I gave myself a very hard time! This was the wrong thing to do, since it inhibited my progress.

- 2) If you get rid of the stress, you stand a better chance of improvement. It's largely what the *eyes* consider to be stressful that is the important thing.

Do you suffer from eyestrain? If you are familiar with eyestrain (and I've never met a myope who wasn't) then you know what stress means to the eye. The mind is willing to go on, but the eyes are not, and so we push our vision past the point where it is able to function normally. If we were lifting weights with our arms, our wills would not be strong enough to push us past the limits of our muscles, but because the eyes are small, they are easily overcome.

The tension of eyestrain is only the grossest form of stress on the eye. There is also what I call "ambient stress" which only myopes seem to have, and that is the stress and strain of the eyes having to stay fixed so that they can see through glasses. This is a technical fact, that when you wear glasses, your eyes must *work* to keep your eyes in place.

Now here's an ill-kept secret; if you've been wearing glasses every waking hour for 20 years, then your eyes have actually atrophied in place, just as if you had worn a cast on your leg for the same amount of time. If you wear

a cast on your leg for 3 or four weeks, then when it comes out of the cast, the muscles will have withered away to virtually nothing, and you won't be able to bend your leg without extensive therapy. Why should your eyes be any different? What do you imagine would happen if you wore a cast on your leg for 20 years?? You'd be surprised to find a leg left at all!

So your eyes, having been kept rigid for years by wearing glasses will need to

be gently worked back into shape so that they can function normally again. This will take time. However, if you just launch into a program of exercise for your eyes, you may only be inadvertently straining them again. The thing that the eyes need to do is learn to relax, and the chief lesson for the eyes to learn is that *the glasses aren't there any more*!

I discovered that if you could *defuse* this remembered stress and tension, instilled by long years of wearing glasses, you could begin to make rapid progress. How do you do that? That is the question, one that took me a long time to answer. I will give you the answer for free, so you can get started straight away, but first I have to explain a few things;

You can't just tell the eyes to relax. Nor can you simply relax them like any other part of the body. The eyes, when they are perfectly relaxed don't focus at all! This fact adds to the problem of learning to deal with visual stress so as to see better. It poses a paradox, the existence of which explains why all the relaxation techniques in the world will not take your visual improvement more than a couple of diopters in the right direction at best. There is an element of dynamism involved that is missing in the idea of relaxation which is added to the technique I am about to describe.

BABY MODE

It took me a long time to discover *the actual active ingredient* in my improvement.

I thought that it was simply a matter of spending time out of doors, looking around, not squinting etc. But there was an exact principle that it took me 5 years to define. Based on this principle, and in conjunction with my Stress Model, I now have worked out a technique which anyone can do, which doesn't involve exercise, and which is the single most effective thing I have ever tried.

I call it Baby Mode, though it is based not so much on how babies see, but on how young children up to the age of 5 look at the world.

It's quite simple. It involves the practice of looking at the world as a child does. That is all. How do you do that? By understanding how a child looks at the world!

What follows is very important and should be considered carefully and understood fully. A child's visual practices are quite distinct from a myopic adult's.

A child;

- Next to never fixates on any single object.
- Their eyes are naturally relaxed, all the time, not tense as myopic eyes tend to get.
- They blink in liquid motion, not forceably.
- They look at things because *the objects of their attention are inherently interesting*, ie, the world is (still) a fascinating place to them.
- They look to learn (a myopic adult is trying to learn to look!)
- Their attention span flits around a lot. They see many more things in the same amount of time. Myopic adults miss seeing many things, even when they are wearing their glasses!
- They look at the whole of any scene, and see it in greater 3D depth.
- They look at things to learn about them (adults already familiar with the world look at things to IDENTIFY them, thus they never really see the thing once they get the ID. Focusing is curtailed.)
- They don't squint, except of course in strong light, and even then, only rarely.
- They don't read in the dark, or in dim light. It puts them to sleep.
- They yawn a lot, and clear their vision by looking away whenever they get tired.
- They never get eye fatigue because they never force themselves beyond the point where fatigue begins to set in.
- They see clearly without even being aware that they are doing so. They never give this autonomic function so much as a moment's thought.

Observe children closely, and you may pick up a few more pointers. Or better yet,
remember how you used to do it!

The main idea here, and this is the key to practicing the technique is to remember how *you* used to look at the world, and put your vision back in its original state. You *used* to do it like this, if you were ever non-myopic. Then you stopped. You need to go back to doing it that way. That's the essence.

Whenever I can't see as sharply as I ought, I remind myself to go back to Baby Mode, and my vision clears immediately.

All the other complex ideas concerning how the eye actually works are interesting, as theories, but if they don't yield a practical therapy, then they are simply academic

excursions. I have a model of myopia, called the Stress Model. The Stress Model yielded the Baby Mode technique. It works well, and is theoretically *sound*. But you can practice Baby Mode without really knowing how or why it works.

The only trick to Baby Mode is learning how to put your eyes into that state, and then remember to keep them that way. You'll see results. Of course, it will take time, but I've tried everything of which I am aware, and this is the safest route to steady rapid progress that I have so far discovered.

MORE ON BABY MODE

* How to Get Into Baby Mode the First Time

First, by remembering its characteristics from your past, then by putting your eyes *back into their past mode of operation*. When I first started doing it, I used to remember my childhood, and the innocent way in which I looked at the world as if it were brand new and made just for me.

Here are two ways to do it;

- The easy way; Cast your mind back to when you were a child and could see clearly. Put yourself back in time and *feel* how it was for you. Have no fear, the flesh remembers. Recall the sheer delight you felt in looking at all of the bright colours, the play of the light on things, etc. See the world in the round, afresh. Discard the tension around your eyes and set aside your adult cares and concerns.

- If you can't remember what it was like to see as a child, then do it like an actor would, as if you had been asked to give a very convincing performance. BE a child for one brief moment, and set your mind in the frame that a child would have. It's not about personality, or being giggly. It's about the way you see the world.

* How can you tell if you're in Baby Mode?

You will know immediately, because when you are in Baby Mode, you will notice an improvement instantly. It may only be slight, but the fact that it has changed in a positive direction is the indicator. Note how above I said that when I remind myself to get back into Baby Mode, my vision clears up immediately... that's the clinical indicator.

* What about Clear Flashes? How does Baby Mode relate to these?

Baby Mode may or may not induce a Clear Flash every time you go into it, but overall, you will see more Clear Flashes the more you stay in Baby

Mode. A Clear Flash is an inadvertant jump into perfect Baby Mode. Baby Mode is a conscious thing you practice till it becomes the unconscious norm. Clear Flashes begin to come more frequently, and last longer.

When I began practicing Baby Mode (the discovery of which was inevitable once I worked out the Stress Model) I started seeing things again that I saw every day as if it was the first time that I had ever observed them. I was startled! Colours became brighter, things got "rounder" and fuller, and lo and behold, sharper! Anything that attracted my attention got it, only I found I wasn't staring at things so intently as I would have before.

But then I would suddenly realise that I was seeing clearly and my *focus* shifted from what my eyes were seeing to what was going on with my eyes. I fell out of Baby Mode and the clouds came over again. No problem... I knew I was onto a good thing. I just slipped back in again, without sweating it, and the same effect occurred again and again.

* Are there any other characteristics of "Baby" vision I should know about? Yes. Children do not constantly check their vision to see if they are seeing clearly.

This is something that myopes tend to do obsessively. It is typical in fact for a child to have a vision problem for weeks before it is picked up, and comes as something of a surprise to them. This is because they give seeing *no attention at all*. It is just something they do automatically.

Its like the situation where most healthy people are not aware of their heart beating, except when it is brought to their attention. A heart patient on the other hand is aware of little else. One can say that even with 20/20 vision, a recovered myope is not cured until seeing no longer absorbs any of their conscious attention. I am almost at that stage after practising Baby Mode. When I've reached it, I'll probably write down everything I know about correcting myopia naturally and then dissappear off the scene, back into the normal world!

UPDATE

If you keep it in mind that young children with perfect vision are constantly in Baby Mode, and myopic adults are next to never in Baby Mode, you'll realise there is quite a gap to be bridged.

Once you know what it feels like, there is minimal effort or disciplined involved. It is now habit and routine for me. At first it required some conscious thought, but now it only takes a moment of remembrance to set things right again.

Don't think though that when you've done it once or twice, that's it. It's not a magic wand. The rule is that if you think you are doing it, but you aren't experiencing an instant improvement, then you are not doing it! Don't then become obsessed with it again. Just remember to do it right whenever you

realise you can't see clearly, and the habit will soon become engrained. That is my last piece of advice.

Soon I will no longer be involved in this field, for the simple reason that myopia will not be an issue for me, and it is better that I stop putting my attention on it. This is one of the principles of Baby Mode, and I know of no other approach which has as its aim the complete elimination of the problem.

You will soon get to this point as well when you are "in the groove" with Baby Mode. Before you leave the scene though, you should pass on this information to others who may be helped by it.

I envisage a time when glasses are no longer perscribed for myopia. Instead, when myopia is detected in both children and adults, a trained person will gently lead the affected person into the (restored) practice of Baby Mode, by getting them to do again what they once were doing, and stop doing what it was that caused the problem in the first place. That is my dream.

But I have no plans of starting a one-woman movement to effect this. This method will live or die on the basis of its results and ease of application. Consequently, if this works for you, if you understand it well and apply it consistently so that you get results, you have then an obligation to reproduce it in others who are in need. One becomes two, two become four, and so on until it becomes common knowledge, and no one would ever *think* to give a child glasses for myopia or operate on corneas again.

I have cataracts in both eyes. Both my eye doctor and my ophthalmologist have expressed shock at anyone my age getting a cataract, especially in such healthy eyes. (I had always thought one had to be AT LEAST about fifty to even think about such things <sigh>.) The one bright spot is that my eyes are reportedly very healthy save for the cataracts.

I am not diabetic (nor are any of my relatives, living or dead), have never had any eye problems, have never used aspartame, and have never taken any drugs or medication save for an occasional Aspirin or Excedrin. I also try to get the proper nutrition, especially C, E, beta carotene, bilberry, and everything else known to be good for the eyes.

To answer several of Alex's questions, I live in the suburbs, but work in a major city. I design computer systems. I don't wear prescription glasses, but do wear sunglasses.

I'm a nervous wreck about this. Any ideas/suggestions anyone has would be very welcome.

Thank you VERY much.

Best regards,

Virginia

I am sorry I do not have a ready healing advice to give you but just wanted to let you know that I have a friend, about 30 years old, who has a cataract in one eye. His eyes are otherwise healthy. He has been to four ophthalmologists and they are clueless as to what might have caused the cataract at such an age. He is now waiting for the cataract to ripen to be operated on.

I suggest you scan Medline to find out if other such cases have been documented and as well as any treatment options. If you support the stress theory as the ultimate cause you may look into that also.

Stefan

I would like to thank Linda for the eloquent description of her journey towards seeing without "crutches".

For the benefit of some of the "doubting Thomas's" I would like to clarify my previously used term "seeing with my heart", used when sharing some of my VT experiences. What I ment by the term is analogous with bringing myself into "Baby mode". I am well in tune with Linda's experiences passed as well as present and although I am not as far as she is, having started my journey only 3 years ago and having measured even stronger prescription at that time (R:-18.0/L:-14.5), I do believe that the baby mode is the ultimate way to reach improved vision.

Being prone to stress but yet at times "pathologically disciplined" - (sometimes to my detriment), my description focused more on the concrete exercises and approaches - rather than on the psychological attitude (the baby mode) for which I was lacking the right descriptive vocabulary.

Thank you Linda for finding the words for me and congratulations on your success. Although I personally don't have the courage to go "cold turkey", the way you did, I am following the path of clear flashes with reduced prescriptions and trying to remember the way I used to see - at least prior to those times, I wanted to forget. The daily "exercise" sessions are actually meditation sessions, sitting in front of eye chart, astigmatism wheel and other shapes and forms, attempting to "work out my Stress Model".

Thanks for the very interesting and inspiring description of your method.

As for the formal trial.. let me digest the information for a bit.

I've known about natural vision improvement techniques for years, and have been giving it a rigorous try since June.

2 years ago, my prescription was -6.5 in both eyes. Last June it was -6.0 in both eyes. Since June, I have been going to a vision therapist once a week and using the accomotrac as well as other techniques like palming, shifting etc. I gained a quick improvement over the first month and am

now at -4.5. After this rapid initial improvement I have not gained any more improvement since then.

This seems to jive with your statement to the effect that other methods can gain a 2 diopter improvement max...

Currently I am trying to go without my contacts/glasses as much as possible and doing palming and shifting. I am trying to use open relaxed focus too, and investigating as many techniques and theories that I can dig up. It is interesting to note that when I sit quietly and pay attention I can actually feel the chronic tension in my eyes-- it is a constant underlying strain. But I cannot voluntarily make it go away. Sometimes I can feel it subside while palming but this is rare and I cannot yet reproduce it reliably.

I may not be a good subject for the baby mode formal trial because I am so familiar with many other techniques and am not starting from ground zero so to speak..

However, I will try (and have already begun to) to give it a go, informally.

Baby mode sounds like "the" technique which worked for you but I am not sure if it will work for all- due to the fact that it is hard for many to actually remember what it was like to have our baby vision. I wonder if hypnosis regression would really help in this matter afterall...

I believe the baby mode method works because it is based on a sound principle which I think we all agree on here- that bad vision is due to improper relaxation, stress and tension.

Like I've read and heard before. Perfect vision is mastered once perfect relaxation is obtained. The methods of obtaining that relaxation are numerous and varied.. some techniques work well for some and other techniques work well for others, but the end goal is the same regardless of the means.

I'd be interested in hearing as much more as you would care to write about the baby mode technique and your progress and recovery.

Thanks again.

well i missed the beginning posts, i don't know how old u are, but i am a medical illustration grad student who changed her 'scrip from -10.75 to -8.00, and am still hoping to go down... i'm responding because i recently illustrated a lens replacement surgery, the whole thing took 60 minutes start to finish and the patient had local anaesthetic only. 15 min to vaccum out the old lens, 5 min to put in a new synthetic lens, 5 min to close up the incision... it was astounding. all the tools were hooked up to a computer and a high mag tv screen, which i drew from. as the doc picked up each tool, the computer said " emulsification" or "coagulation" or whatever. actually those were the only 2 things to be done. i was in awe. I guess i just wanted to share that in the right atmosphere, surgery is not a scary or complicated thing. ... Just in case you would like to solve the problem and worry about the causes later (kind of like the theory, "it doesn't matter who robbed your house, your first goal would be to reestablish your sense of safety/balance") However, this was at Strong Memorial Hospital here in Rochester, NY, where they have a med school, and researchers, and modern top o the line equipment....

anyway, i am doing my graduate thesis presentation about vt, (having the personal vested interest makes this a marvelous project... i will do paintings of eyes and some charts of results and diagrams of Bates and others' exercises... i may come up with a questionnaire for you guys, and i know elena already did, but i have to decide just what kind of info should be included to start. anyway, i do log on and read up but havent had much to type about cos i'm so busy with school and haven't had much "technical" eye change....

well i am with u all in spirit , anyhoo.

eileen

I just wanted to mention that I know two different people (not related) who each awakened one morning unable to see anything but blurry shades of grey, and who were told by a series of ophthalmologists that it was permanent and there was no hope of a cure or recovery.

The first man continued to take beta carotene and Vitamins C and E, and, to everyone's shock (especially the ophthalmologists, who had no explanation for it), his vision returned. He sees fine, still drives, et cetera.

About ten years later, the other man (brother-in-law of the first) awakened to the same problem, and got the same dismal diagnosis from his ophthalmologists. Resigning himself to a life of near blindness, he nonetheless took his brother-in-law's advice and began taking beta carotene and vitamins C and E. His vision returned (to the shock of his ophthalmologists), and he can again read "The New York Times" without glasses, et cetera.

I just thought I'd pass this along in case it was of interest to anyone. It certainly made me a firm believer in beta carotene and Vitamins C and E.

Best regards,
Virginia

Good and interesting post, i was going to mention something about vitamins, and your post has reminded me.

Vitamin A: Known as the "eye vitamin" along with vitamin D.

Vit. A along with protein are the two main components in a substance in the retina called visual purple. Visual purple has to do with our retina turning light into electric pulses sent to the. Bright lights consume Visual Purple. Which might explain why some people wear sunglasses, maybe they don't have enough vit. A. Night Blindness is a the most obvious sign that are eyes are lacking Vit. A. A lack of Vit A leaves your eyes vulnerable to infection such as pink eye. Aswell Vit A is even more useful if you take it with zinc. Vitamin A is found in meats and fish, some milk products, vegetables which contain carotene. Carotene is found in leafy veggies (the darker the better).

Vitamin B: A lack of vit. B can lead to sensitivity to the sun, bloodshot eyes and blind or dark spots. Insufficient B1 =dry burning eyes, aswell as unclear and double vision, and pain behind the eyeball. Lack of B2= burning itchy eyes, reduced acuity, along with light sensitivity or infiltration of blood vessels into the cornea. As well as the development of cataracts. Insufficient B12 = focusing difficulties, headaches and trouble distinguishing red from green. Smoking, coffee and sugar are big consumers of the B Vitamins. Food rich in the B's are : eggs, liver, whole grains, sunflower seeds, nuts, wheat germ.

Vitamin C: A healthy eye especially the lens has a good supply of Vit.C. A lack of Vit. C can cause exophthalmus or better known as bulging eye. Foods rich Vitamin C : Citrus fruit watercress, cabbage, brocoli, just make sure you don't cook them.

Vitamin D: The best source the sun. It works with Calcium. Evidence is accumulating that a lack of D and calcium may lead to myopia. Restoring the supply appears to remove excess fluid from the eye thus reducing the pressure. Foods rich in Vitamin A or also Rich in Vitamin D.

Vitamin E: It help to form new blood vessels, which can stop presbyopia from starting. Aswell as nourish the connective tissues, making them stronger, thus resisting the pressure of near work. Which is good for myopes. Foods that are rich in Vitamin E are big green leafy veggies , aswell as the wheat germ which contains the most Vitamin E.

Chronium: Recent research shows that a lack of Chronium may lead to the development of myopia. Children who were becoming myopic had 1/3 the supply of chronium as the children who were not becoming myopic. Chronium is found in: corn oil, meat, whole grains, brewer's yeast, and sweet and starchy fruits and veggies.

Have fun,

-Peter

Hello, I_seers,

I should appreciate some comments about the disposable contact lenses wearers and wear. In Italy there are many problems because the persons don't wear the DCL for the right time, but use them for a long time.

For example, a weekly disposable contact lens was used for 6 months and not for a week.

If you think this is impossible, you can try to use your DCL for a long period and you can discover that this is really possible.

Now, with the daily contact lens, the problems become bigger, because the people are wearing this lens for 2-3 months.

Italian Ophthalmologist don't say anything about this problems and on the contrary prescribe very often DCL without any preventive eye examination.

What do you think about this ?

Excuse my bad writing English and send your experience on this argument.

Bye, Massimiliano.

I found the post from pdf@freenet.edmonton.ab.ca exceptionally helpful and informative.

Just in case anyone is interested, the eye disease I couldn't think of (from which both men had suffered but recovered their vision completely - to the shock of their ophthalmologists) is macular degeneration.

Best regards,
Virginia

Probably the most obvious pill to take is a multi-vitamin, but i would prefer to take all of the recommended daily intakes through regular food and not depend on a multi-vitamin. Who knows what minerals and other unknown vitamins we might be missing. Proper food with proper exercise, and exposure to the sun (for vitamin D), we should be all right.

Have fun,

-Peter

I Seers,

I got some info:

Sleeping in a dark room, is better for your eyes then sleeping in a room that has some light in it, as well sleeping in darkness stimulates the melatonin production in our bodies.

Thought i would pass that on,

-Peter

Hello Massimilian,

I wonder if the problem is that the opticians are not telling the patients about the dangers involved? I used to wear disposable contact lenses and having been prescribed them from two sources, never have I been told anything other than, "throw them away after 2 weeks of full wear or a month of partial wear". Nobody ever told me what would happen if I didn't....

Caroline

I am not sure if there is an absorption problem with my daughter, that is why I wonder about pills. OcuGuard seems to have a lot of the correct ingredients.

Is'nt it hard to get all from food?

Mei-Tien

Lately I started thinking more about Baby Mode and open focus or nuclear vision. I have been working harder on my vision wearing my glasses less. Now when I read keeping the page a little farther away than what is comfortable my eyes tear profusely. Even last night watching the TV and not wearing glasses straining to see I started tearing a lot. I have had great vision overall lately. Has anyone else noticed that when they are going through stages of improvement their eyes water more?

>

I might seem so but i don't think so, for example i have friends at school who eat probably two litres of Pop a day, instead of learning that sort of habit a drink milk or juice. I think that it all boils down to having your three meals a day. If you miss one your missing a lot of nutrients.

Geting into the habit of eating nutritious food can't be emphasized enough. One of my favorite meals to have is a garden salad.

In canada the recommended amounts of food for the four food groups that should be taken, seems very high (i don't have the exact numbers), yet i dont think very many people even come close to that recommended.

Another thing that i want to mention is that kids complain that they don't like what they're eating. "It's gross", you don't have to like what your eating. That's not the point of eating.

Once again you can't emphasize enough how important proper eating habits are.

Have fun (eating properly)

-Peter

Ever since I started Vt in general I noticed that my eyes water a lot more.
My Ophthalmologist did some test and told me that my eyes don't produce
enough tears on my last eye exam. I think that the reason my eyes or
watering more is the fact that i don't wear my glasses anymore besides
at school. The second i get home i take the glasses off. I've been
wearing glasses for 8 years. I think that maybe because my glasses act
like a shield, that my eyes stop producing as many tears. As too answer
the question, i only notice that when i'm outdoors, but i'm not sure if
it is because my eyes are sensitive to the sun (Not enough Vit A.). I
never tear "profusely" indoors, except when i yawn.

Have fun,

-Peter

There is a web page that has some great info on vitamins minerals, and other things relating to food and health. Heres the address:

[Http://www.hoptechno.com/rdindex.htm](http://www.hoptechno.com/rdindex.htm)

Hope that helps,

"Isn't it hard to get all the nutrients through the food we eat?" If most of your food is cooked, canned, refrigerated, frozen or otherwise processed, then it can be hard to meet your nutritional needs through food alone. And I disagree with Peter: if it seems gross to me, I don't eat it. I believe our bodies have an innate ability to recognize healthful fuel. If a food is unappealing, there is probably a reason for it.

A good example is liver. Almost every nonvegetarian source of information insists that liver is a must for good nutrition. Almost every person I know HATES liver. My mother goes to a restaurant when she feels she needs to eat liver, so that her house doesn't have that awful smell from cooking it afterward. My instincts tell me there is something wrong with the wholesale practice of consuming liver "for your own good."

Consider the function of the liver: filters out "minute foreign particles, bacteria, and gut toxins, ... the liver is often secondarily involved in infections and other systemic illnesses." Not only does the liver filter out drugs and hormones found in the blood, it produces hormone substances of its own. Each liver is finely tuned to serve its host, not the consumer of that host.

Consider, too, how livestock are fed, maintained and treated. Antibiotics are often used prophylactically, since disease spreads quickly in crowded conditions. Hormones have been used to produce "meatier" animals despite youth and lack of exercise. None of this seems very appetizing.

I am no vegetarian, but I don't eat meat every day, much less every meal. I eat many foods raw, or lightly steamed or sauteed. My daughters both eat

vegetables, preferring most raw (carrots, celery, peas, parsley, peppers, tomatoes, squash). They don't like overcooked veggies - the way my mother and grandmother make them. Good instincts, don't you think?

Another modern practice that may make it hard to absorb nutrients is the obsession with low fat. Many vitamins are fat soluble. I have returned to adding olive oil (just a little) to the vegetables I steam or saute. Children, in particular, need some fat in their diet.

I used to blindly accept the wisdom of the experts, but I have seen the prevailing "truth" shift many times in my 39 years. I am paying more attention to my own truths and learning from my own experience. The milk lobby and the beef lobby have a lot to do with our public health standards and recommendations.

Mary (climbing down from the soapbox)

I have found a new "vision fitness" game! It really belongs to my kids, but I think it has real potential for me. It is called "The Lost Mind of Dr. Brain." Sierra is the publisher, and it is a computer game on CD ROM. It works on both Mac and Windows systems.

The game is divided into different areas, each related to a specific area of the brain. Within each area you may Novice, Expert or Genius difficulty levels. In designing this set of games, the Theory of Multiple Intelligences was taken into consideration. Advice is given on strategies for solving the puzzles based on your own style of learning/functioning.

I spent two hours playing with the "3-D Construction." I have good spatial ability, but chose this section because it relates to the brain portion of seeing. One of the narrators even suggests, as you complete some of the puzzles successfully, that your visual perceptions are being enhanced. Many of the comments sound like affirmations.... Neat game! All of the other games are designed to exercise visual/spatial ability, too, along with interpersonal, intrapersonal, kinesthetic/bodily, logical/mathematical, verbal/linguistic, and musical.

At 11:00 10/5/96, Mary Marlowe sent one GREAT post:

>... And I disagree with Peter: if it seems gross to me, I don't eat it.
>I believe our bodies have an innate ability to recognize healthful fuel. If
>a food is unappealing, there is probably a reason for it.

definitely. tuning into the bodies sense is an essential skill to
develop--for vision too!

>...
>Consider, too, how livestock are fed, maintained and treated. Antibiotics
>are often used prophylactically, since disease spreads quickly in
>crowded conditions. Hormones have been used to produce "meatier" animals
>dispite youth and lack of excercise. None of this seems very appetizing.

when i finally took stock of this and quit meat, i noticed excellent
physical results as mentioned prevously. again these toxins, hormones, bad
vibes and what have-you have to be processed by your body causing
additional strain. you are *definitely* what you eat.

>...
>I used to blindly accept the wisdom of the experts, but I have seen the
>prevailing "truth" shift many times in my 39 years. I am paying more

Well if you find it that hard then take a good multi-vitamin along with
your food.

> And I disagree with Peter: if it seems gross to me, I don't eat it.
> I believe our bodies have an innate ability to recognize healthful fuel. If

Let me rephrase what i mean, i'am taking about kids here, a lot of kids
complain that they don't like there vegetables, and all they want to eat
is chips and pop. I agree with you on the point of our bodies having the
inate ability to recognize healthful fuel and so on and that you should
not eat it if you find absolutely revolting, but i think that
part of that ability is developed over a period of time. For example,
plenty of people i know hated tomatoes when they were young, now it's one
of there favorite foods. The point here is not to eat tomatoes, but rather
to try all kinds of foods, and not get stuck into eating the same food
everyday, because

nothing else appeals to you(look, smell...).

Well no one said you have to eat liver everyday, i have to agree with you that liver is probably one of the gross' foods that there is, but still eat it from time to time regardless, because i know its good for my body.

I agree with you there, plenty of farmers are injecting their animals with god knows what now, just to make money. I'm sure some of us know about mad cow disease. Need i say more.

For those seeking a compromise between "eating well" and "popping vitamin pills" I suggest adding the following nutrient-packed foods to your diet:

brewer's yeast
home-grown sprouts
garlic
carrots

Lately I've been drinking three or more tablespoons of brewer's yeast with a little sea salt and honey in water. Tastes great, and when I drink it I can almost swear that my eyes feel relieved immediately.

Sprouts have got to be the easiest-to-grow and most nutritious food available. All you need is a jar and water. I only use filtered water.

Garlic is an acquired taste. I have gotten so used to it that I enjoy it raw a clove at a time.

Carrots of course are the ideal way to get beta CAROTene, precursor of Vitamin A, the "night vision" vitamin. I've heard that you get more nutrition out of them if they're cooked. I like them better raw, though.

just wanted to add that an reflexology book i am reading insists that
sourkraut is a necessity, eat it everyday the author recommends! she
considers it a panaceae. this is one that i can stomach but i dont find
myself getting too excited about.

You had me going for a moment Alex; I thought you were referring to
(e.g. Brussels sprouts - small cabbage-like things, and was wondering
how you grew them in water only).

You mean sprouting seeds / bean-sprouts, of course.

> Garlic is an acquired taste. I have gotten so used to it that I enjoy it

For the less brave, there are several garlic preparations on the market.

I heard that sulfur (or something else) in garlic in big quantities is not good for the eye. Any details anyone know about?

i've followed this conversation and think that it's a wonder-full additive to vt/bates/hypnovision/u name it... it's interesting that working on one aspect of the self tends to uncover other issues... for me baby mode was always present in dance class, until a serious knee injury stopped my pursuance of dance as a possible "career"... all the books i read about healing made me reexamine things i thought were behind me, stuff i went to counseling about, stuff that was painful to recall... part of the baby mode means allowing feelings to flow through you, even difficult feelings... notice how babies cry and scream but as soon as the bottle is given or the diaper is changed it is very easy for them to be in a relaxed happy mode... PRECISELY because they RELEASED whatever emotion welled up within them...

last spring, i was taking aikido. it is a very beautiful, very dancelike martial art, very centered and based on maintaining composure and compassion in all situations... You do a lot of rolling around on the floor, very much like children do... in fact i did assist with the kid's classes because i picked up very quickly and loved the place, so i volunteered... However, while WATCHING a demonstration one evening, as an advanced student sent a very convincing punch to another advanced student, i was immediately emotionally transported to age 17, when my father put my teeth through my lip with a similar punch. I had been laughing and giggling the entire class, this happened completely without warning. and i haven't thought of this stuff in a long time. I began to leak tears, and immediately stopped because people were asking me if i was hurt (concerned about lawsuits, no doubt)... but regardless of the breathing exercises and the self affirmation, my BODY wanted to cry... in no uncertain terms!! it felt as if a vise grip were around my throat... so i quietly excused myself into the hall to let it out... the teacher later came out and i discovered that his wife had actually stopped doing aikido because of a similar reaction... we have similar abusive backgrounds.

He told me of a book called "No Enemies Within" and tho i really didn't need yet ANOTHER 'process your *%#@' book, i got it, cried most of the way thru it, and after 2 more classes with the same reaction, i stopped going to aikido. Made more sense to go to dance class, it always leaves me happy.

Here's the process part: within a week, i had severe lower back pain, like my BODY was saying, ok, you won't cry, i'll give you something to cry about. Ironic, because this is what my father used to SAY. well, after a week i went to a chiropractor and the very next day there were severe chest pains. I thought i was dying. or very seriously ill. keep in mind i am extremely healthy, mostly vegetarian, smoke/alcohol/substance free dancing being... it was very mysterious. that lasted about two weeks. Hasn't happened since. No explanation. Except that recently I've been reading about reincarnation, authors Brian Weiss and Gina Cerminara (BW:Many Lives, Many Masters; Through Time into Healing; -and - GC: Many Mansions)verrrrry interesting. there's a lot of angles to vision, health, and a whole lotta other stuff. Don't close yourself off to other potential perspectives.

... the thing is it was one article i read about reincarnation as it related to health which prompted me to begin VT in the first place...

just
giving you
my 2 cents
to sense... :)

if you are talking about hard lenses, i don't know. But here at school there is an ad for a place where u can buy contact lenses direct, all u need is your prescription and i think u give them your doctor's phone #.(but i bet they don't call.)

here's the address:

Campus Contacts, Inc.
1382 Third Avenue, Suite 242
New York, NY 10021

Tel: 1-800-792-2678
Int'l:1-212-533-0396
Fax:1-212-533-0594

There's a \$5.00 fee if they call your doctor (that's only if u don't have the prescription to give them)

Prices range from \$20.95 for 6 lenses (B&L, Accuvue, CIBA Newvues) on up to 71.50 for B&L Optima Toric Lenses. I'm sure they'll send u info if u ask.

Otherwise, i'd suggest gettin' a friend in a lens manufacturing plant. smile.

well, i wear disposable contacts but i take them out every night. i have separated my prescription into myopia (the contacts) and astigmatism (very thin overspecs) because it is expensive to have the whole thing rolled up into one pair of glasses... after i went thru 2 pairs of glasses in three months, my doctor and i came up with this solution... now, my contacts are -7.25, so they are thicker than the average bear's, and so that is probably why they last so long... i usually do an enzyme cleaning after 2 or 3 weeks, and my "three month supply" (which i think was 6 pairs of lenses) has lasted for a year...

for me, this has been very economical and a rather good solution, as it gives the opportunity to NOT wear the overspecs and still be able to see... plus it's not so cosmetically altering of my face shape. I am fairly diligent about cleaning and usually end up disposing of the lenses because i was sloppy putting them away and inadvertantly tore one ... anyway, that's my experience.

Alex - do you think that carrot juice (no additives, just juiced at home) has enough of all the right stuff? I am trusting that it is mainly fibre that you lose by not eating the whole thing, which is a shame but carrot and grapefruit juice (or carrot, orange and pineapple) are very tempting when you're thirsty.

Was it you I was telling about this tension Art? That tension is the real culprit, and some people have lived with it for so long as an ambient condition that they no longer even sense it. Well spotted!

> But I cannot voluntarily make it go away.

I feel it's safe to say that if you could you'd be cured in short order...

> Sometimes I can feel it subside while palming but this is
> rare and I cannot yet reproduce it reliably.

This tells me you haven't yet got your first breakthrough experience with Baby Mode. I developed Baby Mode as an answer to the deficiencies of palming etc, *specifically* the inability to root out this ambient tension, stress and strain which is *always* there when you can't see clearly.

You've had clear flashes? Clear flashes and this tension you mention cannot co-exist. Note too how when the clear flash goes away it is *replaced* by this ambient tension, which returns within seconds of having put your attention back on how you are seeing. Have you ever noticed how clear flashes come on suddenly, when you aren't paying particular attention to how well you can see?

Have you yet figured out a way to bring on a clear flash? Has anyone been able to teach you how to do this? Therein lies the solution...

I'm giving you all the clues mate! But you have to understand it for yourself, because that's the essential part of practicing Baby Mode effectively. It's not hard, *but it can be made that way.*

Complicating the instinctual function of our vision is one way of describing how we went wrong in the first place. That may be the heart of the whole matter.

>
> I may not be a good subject for the baby mode formal trial
> because I am so familiar with many other techniques and am not
> starting from ground zero so to speak..

Neither was I when I began using the Baby Mode technique. Baby Mode was the last thing I tried, after all else had failed or been mined out.

>

Understood and addressed by my attachment. :-)

> I wonder if hypnosis regression would really
> help in this matter afterall...

My dear friend! Why go to such extremes? You are the perfect candidate for Baby Mode, and you are already so close!!! You already know all you need to know, right now. All the clues are there in what I've already written for you, in your own words, and most importantly, in your own experience. Go back and look. You are within inches of understanding exactly what I am saying! It's going to hit you like a ton of bricks! You'll laugh your head off when you realise how simple it always was, as I did. I'd driven myself nearly batty chasing around for the answer when it was staring me right in the face the entire time. How needlessly complex I had made it for all those years! How absorbed I was *in the problem itself*! Ah, there, you see? I've given the entire game away.

>
> I believe the baby mode method works because it is based on a sound
> principle which I think we all agree on here- that bad vision is due
> to improper relaxation, stress and tension.

This sound principle, by itself, says nothing about the dynamism of actual perfect vision. Remember, relaxation is only half the answer.

>
> Like I've read and heard before. Perfect vision is mastered once
> perfect relaxation is obtained.

Though no one has ever achieved this ideal, to my knowledge, as far as relaxation alone goes. A completely relaxed eye sees nothing at all. Another important clue.

> The methods of obtaining that relaxation are numerous and varied...

Really?

> some techniques work well
> for some and other techniques work well for others, but the end
> goal is the same regardless of the means.

Which is the restoration of one's vision to its original condition, no?
Whether you remember it or not does not matter.

>
> I'd be interested in hearing as much more as you would care to
> write about the baby mode technique and your progress and recovery.
>
> Thanks again.
>
> --

> Blake Systems, Inc.

You are so close! Forgive me if I sound teasing, but I anticipate you will write back to me soon, shouting for joy at the utter (childish) simplicity of it! And for the fact that you can see clearly when you want to, if not at first perfectly, for the first time since you put on glasses.

Your friend,

Linda Wright

PS. Attachment 1 is the one you've already read, but 2 is the new one. Feel free to distribute these to your friends (combined if you like, so they don't get separated).

THE WRIGHT METHOD - AN ALTERNATIVE APPROACH TO CORRECTING MYOPIA

Briefly, I wore glasses for almost 20 years, and I have had some remarkable improvement by using the techniques I will describe below. Other programs exist, but I never had much success with them because they were too complex, involving too much discipline. The way I have finally found involves more a gentle change of lifestyle and seeing habits, and seems to get better results.

The Alternative Approach to Myopia is based on the principle that the body, given half a chance will heal itself. This is a fact. It applies to every part of the body, including the brain, as is now being discovered. Why should the eyes be any different?

When you begin to experience this for yourself, you will find that your initial improvement comes as very brief moments of sudden crystal clarity. These moments are called Clear Flashes, and if you have already experienced them then I am speaking to the converted!

Over time, these moments will become more and more frequent, and they will last for longer and longer periods. They will then begin to predominate, until you are seeing very well most of the time. You will still have situations when you can't see quite as well, such as at night, or in dim light, but even that will start to improve.

I am now in the night/dim light phase. I see perfectly out of doors, and now am beginning to see perfectly inside. This would have been impossible for me even a year ago, when I really didn't know *why* my vision was improving... just that it was. Now that I have gotten to the bottom of the Stress Model, I am polishing off the last deficiencies.

But five years ago, I couldn't read the lines in my own palm more than 6 inches away from my face. Today, I do everything without glasses, contacts or squinting. Tomorrow, my vision will be restored to what it was when I was a child, before it was so casually wrecked by slapping crutches on my face.

Here is my story;

When I was 9 years old, it was discovered that I needed glasses. Whether I actually did or not is a subject of some dispute with me, because as I will explain, what I probably needed more was a break from the stress that had temporarily overwhelmed me and my little world.

It began as boredom in school, and was exasperated by a personality conflict with a teacher who probably disliked me almost as much as I did her. For some reason, she could not see that my rambunctious behaviour was my reaction to the things that were bothering me. My homelife was in a turmoil, another child (my sister) was on the way and my mother was ill. I wasn't coping well, and the class was going too slow for me. I read voraciously to stimulate my mind and escape, and even began reading in the dark under the covers by flashlight. I was a case of lifelong myopia in the making.

My teacher had been writing notes on the board for us to copy for the tenth day straight, and I had had enough. I put my pen down and refused to work. She noted this and became angry. I was headed for trouble and I knew it. When she confronted me, she offered me an out; "Can you see that?" she asked, pointing to her boardwork. I said, "no." She immediately wrote a note to my parents to tell them I needed glasses. By accepting that excuse, I was spared a serious punishment, or so I believed!

Having painted myself into a corner, when I was taken to the eye doctor by my folks, I was anxious to fail my test, because then I would not get into trouble. Now I have to say that failing the eye test was not hard, because I did have a bit of a problem seeing because I was genuinely stressed. But at the time I knew exactly what was wrong, and that I didn't really need glasses even though I did have some slight blurring. I just needed someone to realise that the class was going too slow for me and that I wasn't happy in school.

I got my glasses, and my father insisted that I wear them constantly. I kept trying to go without them (as many mildly myopic children in the same situation so often do). But it was no good. I got in trouble every time my parents caught me without them on, and within two weeks I had a *real* problem. My eyes were

wrecked.

Now I see how I contributed to my own problem, but only after having considered the events of that time over almost 20 long years. At age 9, I didn't have the wisdom or the strength of resolve to stand up for myself and say what was really troubling me. The emotional stress I was going through was real however. In relative terms, an adult in the same situation might have turned to drink or drugs. But enough about that.

I never lost the conviction that wearing glasses was wrong. But I was trapped, and for the rest of my childhood I had to pay for my one moment of weakness. I won't bore you with the details of how bad it is to grow up wearing glasses, because surely you already know what it's like.

But the damage was more than just cosmetic or emotional. At age 16 (after only 7 years of wearing glasses) I received a blow to the head which resulted in a torn retina and surgery. Myopia was doing me damage far greater than what I could have imagined. The surgery was successful, but the risk was always there of further injury. I had floaters and white spot flashes, both classic evidences of myopic atrophy of the eye. I got scared.

By age 29 though, I was more or less reconciled to the idea that there was no solution, and that this was my "cross" in life. The news that surgery might fix my nearsightedness excited me only briefly, since I had already had one operation and didn't look forward to another. I always longed for a cure though. I never gave up hope.

I tried contacts for a while, because over the years, my perscription was getting stronger and stronger. Unfortunately I don't remember what it was, but my eye doctors looked grim whenever I asked them if things were getting better. I suppose I really didn't want to know. In talking to ophthamologists since, we've worked out that it was probably about -10 to -12 diopters at its worst. Very bad.

Then, shortly before my 30th birthday, I had a lucky accident. I broke my glasses, for the umpteenth time, but this time, it was over a holiday weekend, and there was nothing I could do. My contacts were not in any state to be used as a substitute. I was in trouble, or so I thought at the time.

I was virtually blind without my glasses. I couldn't see clearly more than a few inches in front of my face. How was I going to make it through the weekend? I was afraid of getting hit by a car, or falling down stairs.

Wandering around the streets, trying to keep from getting hurt, I ended up playing safe by going into a fast food restaraunt. I was feeling very sorry for myself. Munching on my burger, I happened to glance across the street. I read a sign for a sale, then went back to staring at my food. All of a sudden, it hit me; I shouldn't have been able to read that!

I looked back up at the sign, but once again it was just a big orange blur. Too late though, I had caught my eyes in the act of focusing!

I was shocked! There had been a brief improvement, and contrary to the orthodoxy that I had been taught, this shouldn't have happened!

I had discovered quite by accident that my vision was not set in cement, but that it *varied* slightly from hour to hour. A slight variation, to be sure, from extremely disfunctional to very definitely disfunctional! But it had changed.

The fact that it *changed* was the point. Until that time, I didn't believe it could. Right then I swore off glasses for life, and decided I wouldn't replace the pair I had broken. I went home and I threw out my old contacts and everything that reminded me that I had once worn glasses, save one photograph, which I kept for other reasons. Since that day, I have never put another pair of glasses on my face, and never will.

It wasn't easy going cold turkey. I believed that my vision would improve naturally, out of the influence of my glasses, which I had suspected since childhood had been the cause of my problems all along.

In the time that followed, I realised that my eyesight wasn't going to improve in a week or two. I honestly didn't know why it should take so long, but I tried to find out. It was a slow process of discovery, discarding one wrong idea after another, until I finally had the whole picture of what was holding up the show. Eventually I discovered some basic principles that I will share with you;

- 1) Ordinary Myopia is caused by stress, and stress is the main factor inhibiting its improvement.

Not only emotional stress, but environmental stress. Bad seeing habits like squinting, reading in bad light etc. Wearing glasses of the wrong perscription. This and almost any number of like things can contribute. All of these things, as well as childhood emotional trauma played a part in my myopia, beginning at about age 9. And even after I stopped wearing glasses, in my ignorance I was continuing to generate stress by being anxious to see clearly again. I gave myself a very hard time! This was the wrong thing to do, since it inhibited my progress.

- 2) If you get rid of the stress, you stand a better chance of improvement. It's largely what the *eyes* consider to be stressful that is the important thing.

Do you suffer from eyestrain? If you are familiar with eyestrain (and I've never met a myope who wasn't) then you know what stress means to the eye. The mind is willing to go on, but the eyes are not, and so we push our vision past the point where it is able to function normally. If we were lifting weights with our arms, our wills would not be strong enough to push us past the limits of our muscles, but because the eyes are small, they are easily overcome.

The tension of eyestrain is only the grossest form of stress on the eye. There is also what I call "ambient stress" which only myopes seem to have, and that is the stress and strain of the eyes having to stay fixed so that they can see through glasses. This is a technical fact, that when you wear glasses, your eyes must *work* to keep your eyes in place.

Now here's an ill-kept secret; if you've been wearing glasses every waking hour for 20 years, then your eyes have actually atrophied in place, just as if you had worn a cast on your leg for the same amount of time. If you wear a cast on your leg for 3 or four weeks, then when it comes out of the cast, the muscles will have withered away to virtually nothing, and you won't be able to bend your leg without extensive therapy. Why should your eyes be any different? What do you imagine would happen if you wore a cast on your leg for 20 years?? You'd be surprised to find a leg left at all!

So your eyes, having been kept rigid for years by wearing glasses will need to be gently worked back into shape so that they can function normally again. This will take time. However, if you just launch into a program of exercise for your eyes, you may only be inadvertently straining them again. The thing that the eyes need to do is learn to relax, and the chief lesson for the eyes to learn is that **the glasses aren't there any more**!

I discovered that if you could **defuse** this remembered stress and tension, instilled by long years of wearing glasses, you could begin to make rapid progress. How do you do that? That is the question, one that took me a long time to answer. I will give you the answer for free, so you can get started straight away, but first I have to explain a few things;

You can't just tell the eyes to relax. Nor can you simply relax them like any other part of the body. The eyes, when they are perfectly relaxed don't focus at all! This fact adds to the problem of learning to deal with visual stress so as to see better. It poses a paradox, the existence of which explains why all the relaxation techniques in the world will not take your visual improvement more than a couple of diopters in the right direction at best. There is an element of dynamism involved that is missing in the idea of relaxation which is added to the technique I am about to describe.

BABY MODE

It took me a long time to discover **the actual active ingredient** in my improvement. I thought that it was simply a matter of spending time out of doors, looking around, not squinting etc. But there was an exact principle that it took me 5 years to define. Based on this principle, and in conjunction with my Stress Model, I now have worked out a technique which anyone can do, which doesn't involve exercise, and which is the single most effective thing I have ever tried.

I call it Baby Mode, though it is based not so much on how babies see, but on how young children up to the age of 5 look at the world.

It's quite simple. It involves the practice of looking at the world as a child does. That is all. How do you do that? By understanding how a child looks at the world!

What follows is very important and should be considered carefully and understood fully. A child's visual practices are quite distinct from a myopic adult's.

A child;

- Next to never fixates on any single object.
- Their eyes are naturally relaxed, all the time, not tense as myopic eyes

tend to get.

- They blink in liquid motion, not forceably.
- They look at things because *the objects of their attention are inherently interesting*, ie, the world is (still) a fascinating place to them.
- They look to learn (a myopic adult is trying to learn to look!)
- Their attention span flits around a lot. They see many more things in the same amount of time. Myopic adults miss seeing many things, even when they are wearing their glasses!
- They look at the whole of any scene, and see it in greater 3D depth.
- They look at things to learn about them (adults already familiar with the world look at things to IDENTIFY them, thus they never really see the thing once they get the ID. Focusing is curtailed.)
- They don't squint, except of course in strong light, and even then, only rarely.
- They don't read in the dark, or in dim light. It puts them to sleep.
- They yawn a lot, and clear their vision by looking away whenever they get tired.
- They never get eye fatigue because they never force themselves beyond the point where fatigue begins to set in.
- They see clearly without even being aware that they are doing so. They never give this autonomic function so much as a moment's thought.

Observe children closely, and you may pick up a few more pointers. Or better yet, *remember how you used to do it!*

The main idea here, and this is the key to practicing the technique is to remember how *you* used to look at the world, and put your vision back in its original state. You *used* to do it like this, if you were ever non-myopic. Then you stopped. You need to go back to doing it that way. That's the essence.

Whenever I can't see as sharply as I ought, I remind myself to go back to Baby Mode, and my vision clears immediately.

All the other complex ideas concerning how the eye actually works are interesting, as theories, but if they don't yield a practical therapy, then they are simply academic excursions. I have a model of myopia, called the Stress Model. The Stress Model yielded the Baby Mode technique. It works well, and is theoretically *sound*. But you can practice Baby Mode without really knowing how or why it works.

The only trick to Baby Mode is learning how to put your eyes into that state, and then remember to keep them that way. You'll see results. Of course, it will take time, but I've tried everything of which I am aware, and this is the safest route to steady rapid progress that I have so far discovered.

MORE ON BABY MODE

* How to Get Into Baby Mode the First Time

First, by remembering its characteristics from your past, then by putting your eyes *back into their past mode of operation*. When I first started doing it, I used to remember my childhood, and the innocent way in which I looked at the world as if it were brand new and made just for me.

Here are two ways to do it;

- The easy way: Cast your mind back to when you were a child and could see clearly. Put yourself back in time and *feel* how it was for you. Have no fear, the flesh remembers. Recall the sheer delight you felt in looking at all of the bright colours, the play of the light on things, etc. See the world in the round, afresh. Discard the tension around your eyes and set aside your adult cares and concerns.

- If you can't remember what it was like to see as a child, then do it like an actor would, as if you had been asked to give a very convincing performance. BE a child for one brief moment, and set your mind in the frame that a child would have. It's not about personality, or being giggly. It's about the way you see the world.

* How can you tell if you're in Baby Mode?

You will know immediately, because when you are in Baby Mode, you will notice an improvement instantly. It may only be slight, but the fact that it has changed in a positive direction is the indicator. Note how above I said that when I remind myself to get back into Baby Mode, my vision clears up immediately... that's the clinical indicator.

* What about Clear Flashes? How does Baby Mode relate to these?

Baby Mode may or may not induce a Clear Flash every time you go into it, but overall, you will see more Clear Flashes the more you stay in Baby Mode. A Clear Flash is an inadvertent jump into perfect Baby Mode. Baby Mode is a conscious thing you practice till it becomes the unconscious norm. Clear Flashes begin to come more frequently, and last longer.

When I began practicing Baby Mode (the discovery of which was inevitable once I worked out the Stress Model) I started seeing things again that I saw every day as if it was the first time that I had ever observed them. I was startled! Colours became brighter, things got "rounder" and fuller, and lo and behold, sharper! Anything that attracted my attention got it, only I found I wasn't staring at things so intently as I would have before.

But then I would suddenly realise that I was seeing clearly and my *focus* shifted from what my eyes were seeing to what was going on with my eyes. I fell out of Baby Mode and the clouds came over again. No problem... I knew I was onto a good thing. I just slipped back in again, without sweating it, and the same effect occurred again and again.

* Are there any other characteristics of "Baby" vision I should know about? Yes. Children do not constantly check their vision to see if they are seeing clearly.

This is something that myopes tend to do obsessively. It is typical in fact for a child to have a vision problem for weeks before it is picked up, and comes as something of a surprise to them. This is because they give seeing *no attention at all*. It is just something they do automatically.

Its like the situation where most healthy people are not aware of their heart beating, except when it is brought to their attention. A heart patient on the other hand is aware of little else. One can say that even with 20/20 vision, a recovered myope is not cured until seeing no longer absorbs any of their conscious attention. I am almost at that stage after practising Baby Mode. When I've reached

it,
I'll probably write down everything I know about correcting myopia naturally and then disappear off the scene, back into the normal world!

UPDATE

If you keep it in mind that young children with perfect vision are constantly in Baby Mode, and myopic adults are next to never in Baby Mode, you'll realise there is quite a gap to be bridged.

Once you know what it feels like, there is minimal effort or disciplined involved. It is now habit and routine for me. At first it required some conscious thought, but now it only takes a moment of remembrance to set things right again.

Don't think though that when you've done it once or twice, that's it. It's not a magic wand. The rule is that if you think you are doing it, but you aren't experiencing an instant improvement, then you are not doing it! Don't then become obsessed with it again. Just remember to do it right whenever you realise you can't see clearly, and the habit will soon become engrained. That is my last piece of advice.

Soon I will no longer be involved in this field, for the simple reason that myopia will not be an issue for me, and it is better that I stop putting my attention on it. This is one of the principles of Baby Mode, and I know of no other approach which has as its aim the complete elimination of the problem.

You will soon get to this point as well when you are "in the groove" with Baby Mode. Before you leave the scene though, you should pass on this information to others who may be helped by it.

I envisage a time when glasses are no longer prescribed for myopia. Instead, when myopia is detected in both children and adults, a trained person will gently lead the affected person into the (restored) practice of Baby Mode, by getting them to do again what they once were doing, and stop doing what it was that caused the problem in the first place. That is my dream.

But I have no plans of starting a one-woman movement to effect this. This method will live or die on the basis of its results and ease of application. Consequently, if this works for you, if you understand it well and apply it consistently so that you get results, you have then an obligation to reproduce it in others who are in need. One becomes two, two become four, and so on until it becomes common knowledge, and no one would ever *think* to give a child glasses for myopia or operate on corneas again.

BABY MODE CLARIFIED

There has been a fair bit of discussion on how to get started with Baby Mode, in

particular, concerning the problem of how to remember how you once looked at the world.

I would not want to see the demonstrable benefits of using this technique limited to only those who by some good fortune are able to remember their childhood clearly, thereby excluding those who do not or cannot.

Therefore, I have to correct any mis-impression there might be surrounding the principles of Baby Mode and the supposed need to "remember" one's childhood in order to do it.

Very simply put; It is not necessary to remember one's childhood in order to initiate Baby Mode. The actual active ingredient in Baby Mode is the restoration of the original mode of seeing. Remembering your childhood is but one way of helping in this regard. Memory is a fickle friend, and even those who remember their childhood perfectly do not as a consequence experience Baby Mode. That is because memory remembering your childhood is not the trick.

I don't want this to seem at all cryptic. Please recall my original post introducing Baby Mode. I wrote;

> I call it Baby Mode, though it is based not so much on how babies see, but on how
> young children up to the age of 5 look at the world.

> It's quite simple. It involves the practice of looking at the world as a child
> does. That is all. How do you do that? By understanding how a child looks at
> the world!

Simply by *understanding well* how a child looks at the world, you can accomplish Baby Mode. That is the core principle. Only later on in my post did I introduce the idea of "remembering" how one used to do it. Remembering is a shortcut to understanding, if you can accomplish it. What I am saying is that all that is necessary is adequate understanding and an act of will. It still can be done, and rather easily, even by those who remember nothing of their early years.

I went on to say,

> What follows is very important and should be considered carefully and understood
> fully. A child's visual practices are quite distinct from a myopic adult's.

This is the basis of what must be well understood. In detail, in order to give people a headstart, I enumerated the key points...

> A child;
>
> - Next to never fixates on any single object.
> - Their eyes are naturally relaxed, all the time, not tense as myopic eyes
> tend to get.
> - They blink in liquid motion, not forceably.

> - They look at things because *the objects of their attention are inherently
> interesting*, ie, the world is (still) a fascinating place to them.
> - They look to learn (a myopic adult is trying to learn to look!)
> - Their attention span flits around a lot. They see many more things in the same
> amount of time. Myopic adults miss seeing many things, even when they are
> wearing their glasses!
> - They look at the whole of any scene, and see it in greater 3D depth.
> - They look at things to learn about them (adults already familiar with the
> world look at things to IDENTIFY them, thus they never really see the thing once
> they get the ID. Focusing is curtailed.)
> - They don't squint, except of course in strong light, and even then, only rarely.
> - They don't read in the dark, or in dim light. It puts them to sleep.
> - They yawn a lot, and clear their vision by looking away whenever they get tired.
> - They never get eye fatigue because they never force themselves beyond the point
> where fatigue begins to set in.
> - They see clearly without even being aware that they are doing so. They never
give
> this autonomic function so much as a moment's thought.
>
> Observe children closely, and you may pick up a few more pointers.

You see? Anyone can come to understand the essential principles involved, by reason
alone. There is nothing mysterious or complex about it.

Once you understand it, all you need to do is do it, that is to say, all at once, put
your visual behaviour back into that mode. Not by thinking about a list of things
to do, but by seeing the world as a child does, as you once did. In short,
be a child again in the way you see.

Bad vision is a *habit* for most of us. The old bad habits need to be replaced
with new good habits. How do you do that? That is the secret of Baby Mode. That
is what Baby Mode essentially accomplishes, far more quickly, painlessly and
easily than most other methods I've seen. But the key is understanding, not memory.

The practice of Baby Mode is analogous to realising that you have the habit of
frowning all the time; When you first realise this, and that you look far more
attractive when you smile, you must for a time remind yourself to start smiling
again.

Initially it will be difficult, because it won't seem *right* and it won't look
genuine. So to get it right, you have to smile sincerely from within, by thinking
of something worth smiling about.

Now you can *remember* something worth smiling about, or you can *contrive* something
worth smiling about. But only when you've got it right in your mind will it work on
your face. You will fail many times, and slide back into frowning for weeks yet.
But
you will get it right eventually, and then smiling will be effortless and natural.
That by the way is an almost perfect analogy of how Baby Mode actually works.

Incidentally, just as you can't force a sincere smile, so you can't force Baby Mode.
Force and effort are antithetical to both smiling and seeing. Only three inches
separate the muscles that perform both functions... isn't that interesting!

As well, and some of you have already realised this, Baby Mode is NOT just another relaxation technique. Relaxation will only take you part of the way, a very short distance in fact. Relaxation may prevent your eyes from getting worse, and you may get early improvement from it, but it will not take you the rest of the way. Before I discovered Baby Mode, I was one of those people who'd gone 90% of the way to 20/20 and spent at least two years trying to fix the last 10%. I needed Baby Mode to finish what I had started in throwing away my glasses.

Why is Baby Mode different to the general relaxation techniques we have all been trying to follow with mixed results? Because relaxation is passive, and Baby Mode is active. A *totally* relaxed eye will not be able to focus. The eyes are active organs, constantly in action. They *have* to move in order to work. That's why relaxation is not the entire answer.

SUMMARY

This, then is the full context in which I wrote the line

> Or better yet, *remember how you used to do it!*

Of course, if you can remember, then great. But I must say clearly now, that remembering how you saw as a child *by itself* will accomplish absolutely nothing. I know, because I spent many many hours doing exactly that. Only when I realised that I could put my visual behaviour back into its originally perfect mode of functioning by a conscious act of will did I then directly experience change under conscious control. That one realisation, *that I could do it* was the key. It worked the instant I got it right.

>From that initial success, I persisted, making the rule,

> Whenever I can't see as sharply as I ought, I remind myself to go back to Baby Mode,
> and my vision clears immediately.

There you have it. Rememberance is nothing without the conscious action of the will to restore the vision to the original mode of operation. That you can do by reason, aided by memory, but not by memory without reason.

Finally, in this vein I wrote,

> All the other complex ideas concerning how the eye actually works are interesting, as
> theories, but if they don't yield a practical therapy, then they are simply academic
> excursions.

I would not like Baby Mode to become an academic exercise or a magical mystery tour. It's not a navel-watching thing. It's something that anyone can do. As soon as you've done it once, you'll never forget it or forget how to do it. You will see an instant difference in your vision the minute you've done it. It then

becomes a simple matter of remembering to do it again, every time you become aware that your vision is not 100%. After a few weeks or so, as with correcting a permanent frown, it will become second nature, and your advancement will be steady and predictable.

Of course, if you were never confused about how to do this, and you've already done it for the first time, then there is no problem. But if not, or if you are struggling a little bit, this should hopefully help you get on track.

Nothing in all the world would please me more than to know that you have won your well-deserved freedom with this technique.

I've heard that some ppl can get addicted to carrots/carrot juice, and it doesn't do the liver much good in vast quantities. I don't necessarily take some of the alarmist reports I've heard about it at face value, but nevertheless, moderation, as in all things, is probably wise.

I would not like Baby Mode to become an academic exercise or a magical mystery tour. It's not a navel-watching thing. It's something that anyone can do. As soon as you've done it once, you'll never forget it or forget how to do it. You will see an instant difference in your

vision the minute you've done it. It then becomes a simple matter of remembering to do it again, every time you become aware that your vision is not 100%. After a few weeks or so, as with correcting a permanent frown, it will become second nature, and your advancement will be steady and predictable.

Of course, if you were never confused about how to do this, and you've already done it for the first time, then there is no problem. But if not, or if you are struggling a little bit, this should hopefully help you get on track.

Nothing in all the world would please me more than to know that you have won your well-deserved freedom with this technique.

1 October, 1996

regarding smiling and baby mode. After reading Linda's first post on baby mode I thought about what she was saying then pretended I was a child my face naturally changed I was smiling with my eyes open wide and I could instantly see clearer. It feels like you are loosening your face, relaxing it but also making it more alive. I think from my understanding, this is baby mode to be relaxed and awake, alive at the same time. It is not passive. But it is very natural. You are reaching out to clarity not waiting for it to come to you.

best of luck to all
alexandra

The problem with this baby-mode thing is that babies don't necessarily see perfectly, do they?

I thought this was the whole idea behind "lazy eye" theories.

Not that it's not interesting though.

On Linda Wright's writings on Baby Mode...

I feel baby mode is a good thing. It should be active as you pointed out, meaning one should be "working", at least subconsciously, towards better vision. Note, this is contrary to Bates' idea that one should not be thinking about vision. Of course, things change.

I am having trouble seeing the exact difference between relaxation and baby mode though, as for me (and Alex, if I remember right), relaxation is an active technique, you don't just melt down.

Mike Ellwood wrote earlier today
> The problem with this baby-mode thing is that
> babies don't necessarily see perfectly, do they?

That is true. Babies are born usually hyperopic and they don't see perfectly for a year or so until the so called process of emmetropization is complete.

Linda Wright wrote:

I have an acquaintance who has had the right eye enucleated following an accident. Can you tell me what he could do to grow a new, healthy eye? Thanks.

Some time ago I came across a book on the Bates Method which I have not seen mentioned on the Net. I have to confess to being a little biased in favour of the author as I've had a few lessons from him, which produced my first "clear flashes". Once you've had one of these you'll never doubt the possibility of visual improvement.

The book is not "a how to book", but does describe many of the standard techniques. It also covers how Bates came to his discovery, how the eye works, conditions of sight, diseases of the eye and several case historys.

AUTHOR: Peter Mansfield
TITLE: The Bates Method
PUBLISHER: Optima Books
ISBN: 0 356 21094 4
DATE: 1995 (Revised Edition)

I think I am questioning the premise that any baby sees perfectly. Surely in the early stages they are still learning how to use their eyes properly. They may have the potential to see perfectly, but it may not be realised yet.

I am, by implication, therefore questioning the idea that if only we could somehow reverse the process of having spoiled this once perfect eyesight by lots of close reading, eyes glued to screens watching MS Windows by day, Roseanne/Friends/CNN by night, and get back to that perfect, baby stage, all would be ok.

>perfectly, do they?

Since i'm not sure if Linda has resubbed with her new address, i'll venture to speak for the 'baby mode' as I understand it. The first thing to note is that the term 'baby mode' is an effort to describe a state of mind in seeing the world, one that is interested and open among other things, not specifically to recreate the physical state of the infant (and she also mentions that the age around 5 is more specifically her 'model age' .

Secondly, I have heard that notion that babies dont see well but i believe it to be a misunderstanding of the process. In observing my two kids at that age i noted their eyes tendency to wander and not appear to focus on things. What i believe is actually happening, is that in those first days, the mind is a clean slate and the eyes are collecting lots of colors, textures, and such, but these sensations are 'meaningless'-or rather 'one color/shape/texture is just as good as another '. The front of a chair leg is a rounded and long thing, the carpet is a jumble of little long things, the sky is really large blue. After looking at several long skinny upright smooth things a few more times one starts to notice that all the pieces are connected together to form an object which is a lot like another object with similar characteristics. Sometime later they are informed that this object is a 'chair'. As they become familiar with the *objects* we start to credit them with the ability to *see*. This process gets intensified as we increase our education, to the point that one no longer spends time checking out the nuances of one chair leg or another, we just aim our butt

for it and sit down.

this fact is a **very useful** meditation for vision therapy. Slow down and see all the nuances and dont be concerned with recognizing objects. In this instance, the 'baby mode' is right on i'd say.

>

>I thought this was the whole idea behind "lazy eye" theories.

don't know about those.

The RDA for vitamin C at least is usually acknowledged to be way below what it ought to be; is the same perhaps true for Vitamin A?

Does anyone know roughly how many fresh, raw carrots equal 20mg beta-carotene?

What is 5,000 IU of vitamin A in terms of mg of beta-carotene (and weight/number of carrots)?

If beta carotene isn't toxic, does that mean that turning orange (if one went that far) would be an inconvenience for as far as wearing red clothes goes, but wouldn't actually matter too much to your health?

Caroline

The question is, what do you do when focusing on the list of things that show how a child's vision is different from a myope's doesn't produce any change? I understand everything Linda says intellectually, but can't 'see' any difference. I try not to stare, try to blink, try to look to learn, try to see it all through fresh eyes, try not to try - but all with no result (other than the fact that not fixing on anything tends to disguise the fact that you couldn't read a sign if you did fix on it).

Anyone else have this problem? Anyone solved it? Or is baby mode fine if it just happens to 'click' with you.

Caroline

Sorry to persist with this, but I have to work out if one or two carrot and fruit juice drinks a day (3 - 5 carrots) is too much!

0.6 micrograms of beta-carotene gives 1IU of vitamin A

5,000IU of vitamin A would be (5000 x 0.6) = 3000 micrograms beta-carotene, which equals 3mg.

Conclusion - the RDA of beta-carotene is 3mg (and 20mg is enough to turn you yellow but is non-toxic) - anyone disagree?

We're now down to the last two questions:

1. How many carrots = 3mg of beta-carotene?
2. Does turning yellow matter health-wise since beta-carotene is non-toxic? Or does the yellow-ness indicate that the liver can't cope with the breakdown and is therefore under stress? If so, why do people say beta-carotene is non-toxic? Just because it is LESS toxic than retinol?

Caroline

Vitamin A, 1 IU Retinol=0.300 - 0.344 "micrograms" (toxic form of vit A)
Vitamin A, 1 IU Beta Carotene = 0.600 "micrograms" (non toxic form of vit A)

I have also seen written that 25,000 IU of Beta Carotene = 15 "milligrams"

I think the idea of returning to pristine sight using children as a model is a very good one. It's one model among many. I happen to disagree with our socially conditioned notions of old age, though, so the "baby mode" model has an appeal for me. We can use the model without getting metaphysical about it. To "reverse the process of having spoiled this once perfect eyesight" by any means is a model and presupposes underlying beliefs, as is the idea of healing eyesight, which, though perhaps not obvious, is really a slightly different model and presupposes less.

But why am I writing all this?

Have space!

Mark

I have this book and have personally met Peter Mansfield. In actual fact, while visiting Britain later this month, I will be attending a holistic vision conference in Brighton that Peter has put together with a group of vision educators from all over the world. I look forward to sharing and dialoguing with these folk. I like Peter's interpretations and expansion of of the Bate's book and do recommend it to others.

Best wishes,

Robert-Michael Kaplan

Super blue green algae

- To: i_see@indiana.edu
- Subject: Super blue green algae
- From: "Peter F." <pdf@freenet.edmonton.ab.ca>
- Date: Thu, 10 Oct 1996 13:36:22 -0600 (MDT)
- Sender: owner-i_see@indiana.edu

I_seers,

Has anybody heard of this blue green algae stuff? it's suppose to have 70 times more beta carotene then carrots, as well as having large doses of other vitamins and minerals.

Has anybody had any experiences with this stuff ? if so i would like to hear about it ?

I have attached some info on the BGA (blue green algae)

Have fun,

-Peter

Nutritional Profile of

Super Blue Green (tm) Algae (Aphanizomenon flos-aquae)

Overview

- * Rich in Beta Carotene (pro-Vitamin A) (70 times more than carrots, 6 times more than yoghurt).
- * Algae are virtually the only plant to contain all the essential amino acids, and these are present in the ideal proportions for the human body.
- * Excellent Source Of B-12 (65 times more than kelp and 19 times more than spirulina).

- * More than 40 Minerals tested up to now.
- * SBGA contain nearly all the vitamins the body requires.
- * 50% to 70% Vegetable Protein (by dry weight), one of the highest known sources in the world.
- * 97% assimilable by the body.
- * Freeze-dried (not heat processed) to protect the beneficial enzymes and heat sensitive vitamins such as Vitamin F, B1, B12, C and nicotinic acid.

- * Minerals Owing to its being nourished with water from geothermal springs and volcanic mountain streams, the Klamath algae contains a wide range of chelated (organically bound) minerals, including: boron, calcium, chromium, cobalt, copper, iron, magnesium, manganese, potassium, phosphorus, selenium, sodium, sulphur, titanium, vanadium and zinc. On the average, the algae's mineral volume falls roughly between that of alfalfa and seaweeds.
- * Vitamins and Co-vitamins- The algae's vitamin co-factor profile is unusually uniform and complete for any single food. It is particularly rich in the B vitamins, including B-12, and beta-carotene (vitamin A precursor.) (More on beta-carotene shortly.)
- * Protein- Aphanizomenon flos aqua contains as much as 60% pure assimilable protein, perhaps its most significant nutritional feature. While eating 1 or 2 grams of algae per day obviously won't supply much volume of protein per se, it is the qualities of the algae's protein that is the source of researchers excitement. Its amino acid profile (including the so-called "essential amino acids", ie., those that we apparently cannot synthesize ourselves), is strikingly parallel to our own. Because of this, blue-green algae has been found to enhance assimilation and utilization of other proteins consumed, particularly for those eating a vegetarian, raw foods or macrobiotic diet. Many of the foods that would normally nourish us and protect us from disease apparently are but shadows of their former selves, so deeply have we weakened them by depleting the environments in which they're grown (As another example, USA figures show that today's wheat often contains as little as 20% of the protein it used to have.)
One gram of blue-green algae contains about 1400 micrograms of beta-carotene (blue-green algae enthusiasts generally consume roughly one or two grams a day.) To obtain this much beta-carotene, one would have to consume 14 grams of liver, 70 grams of carrot, 14 eggs, or 5 quarts of milk.

The courses are given in North America as well and I enclose more detailed information for your perusal. We are actually based outside Vancouver, B.C., right in your back yard. Enjoy.

Courses With Robert-Michael Kaplan in 1997

During these past few years I have had the pleasure of educating many people on how to clear perceptions, enhance vision and witness its impact upon the wellness and clarity of sight through the eyes. I realise that my

favourite way of sharing this information is in a get-away 'retreat' setting. The results of these courses are very impressive. It impacts, not only people's eyesight, but the way they begin living more in their truth and from a loving place. Here are some recent comments:

"I learned more about healing than I had ever imagined for myself and others. A kick in the rear to help realise what I am all about."
Darren Sass. 3rd year Optometry student

"You will be challenged. Be prepared for fun, laughter, and tears. Anything can happen in this shamanic journey from healing ourselves to healing the blindness of the planet. Be willing and be open to an abundance of love - your life will be changed forever."
Maggie Eaton - Toronto, Ont. Canada.

"You are a very important player in healing our planet and our people. Everyone present came back with precious gifts to enhance their life and vision."
Kristeen Verge, B.C., Canada

"The Power Behind the Eyes course is a self-directed learning experience to identify, clarify and put into practice self-causal relationships."
Arnold J. Gendleman, Heidleberg, Germany

". . . inspiring, practical and fun. The course is a fascinating, in-depth, way of seeing your vision and your relationship to the world - incredible!"
Sanjay Chaudhuri M.D. - London, England

In 1997 I am offering 2 Ten day events in Western Canada - July 11-20 or August 21-30, 1997 and 2 Seven day courses (different topics) in Southern France - September 1st to 7th and September 8th to 14th, 1997. Because of the experiential nature of these programs the class size is limited to 20 persons. It is therefore imperative you make an early booking. We are providing early bird registrations for those people who wish to commit early and receive a substantial discount.

Sechelt, B.C. Canada-July 11 to 20, & August 21 to 30, 1997
"Seeing Deeply - A clearer vision of your life and purpose " Two 10-day Intensive Retreats in Integrated Vision Therapy. In this course, participants will have the opportunity to deepen their understanding of their vision fitness training. Dr. Kaplan will prepare each person for a program of vision fitness practices. The workshop will include a demonstration of the training eye charts, colour balancing kit•, workbooks and audio tapes used for enhancing vision. Specific training with light, body movement and self-healing with acupressure will be emphasised. You will leave this workshop with concrete steps to guide you in new ways of

seeing clearly in your daily life and gain beginning certification to help others. And more! Early bird registration, if paid in full by May 15th, 1997 is \$2695 (\$2075* U.S.), normally \$2895 (\$2230* U.S.), and includes training materials, taxes, accommodation and gourmet vegetarian meals. A non-refundable deposit of \$695 (\$535* U.S.) secures your space. Visa and Mastercard are accepted in Canadian dollars and a 3% handling fee is added. Contact our office at (604) 885-7118.

Montarel, France - September 1 - 7, 1997

The Power Behind Your Eyes

Explore how your inner perceptions program your vision and eyes to see your world blurry or clear. Discover how to connect more to life through your eyes, sharpening your natural eyesight and restoring function to diseased eye tissue. A recent participant, Nancy Varga, described this course as: "A brilliant marriage of soul and science, personalised for your development."

Montarel, France - September 8 - 14, 1997

Eyes, Sex and The Soul - Creating Freedom For Men and Woman to Connect Transform your personal relationships. Your family tree influences, as revealed by the iris of the eye, is used to create clear perceptions of intimacy, sensuality and sexuality. The course gives single persons or couples the opportunity to open up to their heart felt 'soul love', thus deepening their connection to all aspects of living and loving. Ideal course for single persons or couples.

Early bird registration, if paid in full by June 15th, 1997 is £625*, \$945* U.S. & \$1295 Canadian, normally £725*, \$1095* U.S., \$1495 Canadian and includes training materials, taxes, shared accommodation and gourmet vegetarian meals. A non-refundable deposit of £175* (\$265* U.S., or \$365 Canadian) secures your space. Contact our office at (604) 885-7118 or in Europe call Pélé at 44 171 584-9080. Visa and Mastercard are accepted in Canadian dollars and a 3% handling fee is added.

I know that the amount of Beta carotene per carrot can have quite a range.

For an average, 70 grams of carrots = 220 % of RDA

Have fun

Bill;

I think you are right on with your ideas about how baby's see. If you measure a 6 month old's visual acuity with Visally Evoked Potential, it is 20/20, ie, their visual cortex receives the info. If you measure it behaviorally, ie, with a preferential looking card, it measures 20/200 plus or minus one octave. So the brain IS receiving detailed informatin, but the baby doesn't quite know what to respond to or perhaps how.

In replying to an inquiry about blue green algae, I just realized that I mentioned only Cell-Tech (which is a distributor for what I've been told is the best form).

You can purchase blue green algae (spirulina) at virtually any health food store. I was thinking of Cell-Tech (which is available from distributors) only because that's the kind I've been told is the best, and which I, myself, am about to try. However, I have never actually used it so cannot say for sure one way or the other. (I am very eager to hear others' experiences.)

At 10:22 10/11/96, Richards, Caroline wrote:

> I try not to stare, try to blink, try to look to learn, try
>to see it all through fresh eyes, try not to try - but all with no result

as you note, the key word in this sentence is TRY. Trying is not part of vision-or any form of DOING. I have dealt with this many times myself in many arenas and there is usually a cross-over point when you are suddenly aware of the fact that you are no longer trying-you are actually doing said thing, and then you start refining your technique and wonder how come you had 'that attitude' like you couldnt do this thing!

This baby mode essay has resonated for me on many of the key points that i have discovered along my quest. I see it as obvious and well-stated, but the words are not necesarily going to make a phenomenal change alone. Just more encouragement/provocation.

You will do it alone!

-Bill

44. Thou strivest ever, even in thy yielding thou strivest to yield-and lo!
thou yieldest not.

45. Go thou into the outermost places and subdue all things.

46. Subdue thy fear and thy disgust, then yield!

>> Has anybody heard of this blue green algae stuff? it's suppose to have 70 times more beta carotene than carrots, as well as having large doses of other vitamins and minerals.

I have not yet tried this, but am about to do so.

A former colleague has a friend who had been exhausted all the time, and doctors could do nothing. Someone suggested Cell-Tech's super blue green algae, she began taking it, and has been a powerhouse ever since. Several other people (including my former colleague and his wife) tried it, and were also thrilled with the results.

I have not heard anything negative, and have heard many rave reviews. These are from people I trust, and who carefully investigate everything they put in their bodies.

So I'm about to try it.

Dear Seers:

Something in one of the last Baby Mode posts reminded me of this piece called "Wonder." It's not a direct correlation but in some ways, over, around, and all through it relates to the aspects of vision delineated in Linda's words as "> - They look at things because *the objects of their attention are inherently

> interesting*, ie, the world is (still) a fascinating place to them."

best wishes,

freda

Mel Bucholz from a workshop called "Healing with Hypnosis," Open Center 11-87

There is a man or a woman or simply a being over here that is Wonder. Now this Wonder is in a sense, in varying degrees, glowing and in a shape of an object that you like - whatever it may be. Its skin is extremely delicate. And it is - purely - raw energy. And it may be in the form of a ball in space or it may be a body of some kind. And this has just entered the room here and it is known as Wonder by virtue of my identifying it feeling wondrous in its presence. Its come into the room and it's astounding and awesome for me to engage. I can barely think of proper manners to accord it my attention. In some way I don't know how to be with it without interrupting it - it is so profoundly excellent and purely wonderful. My job, it tells me, is to take it out into the street and to ferry it through the streets and to make sure to be careful because its skin is very delicate and it can be ruptured and broken apart very easily. Yet it tells me that by doing this all of my activities and my experience in my life and everyone who comes into contact with me will be illuminated in a terrific way by virtue of my handling it properly. So that it becomes very important, as I understand it, to move things out of the way and to guide it and direct it in such a manner since it has no eyes or hands or legs of its own. It's simply a floating phenomenon that can be, in some way, directed by the action of my movement and reality - which creates a path for it to move along - it can continue to move out into the world but it requires me to

prepare a way to make sure that it is uninterrupted at any point - that if it is interrupted, in a sense, it will either vanish or withdraw or in some way otherwise completely recede from existence - so with that in mind I am taking it out into the world and ordering a taxi and buying tokens and have to be careful where I'm putting it and in the initial stages I stumble and I'm a little afraid and overly protective - and so on and so forth - to have this incredibly magnificent thing to take care of and shepard around - I also have to park the car and go in and out of where I live and go to stores - and everywhere I go this particular things says to me, "You may carry me with you and bring me with you. I'm interested in being with you everywhere you want to go and things that you want to do. I'm willing to lend to you all of the vitality and the freshness and newness and all of the healing qualities that I am capable of lending to you and that these will work constantly. However, the only requirement that I am given some sort of honoring in terms of watching that I do not get broken or dropped or in some way unfairly represented."

And so on. So it starts to become clearer and clearer to me what it is to do, how to go about doing it, when and where, and who to speak to and how much time to spend in these various encounters. I wonder if you can think of some ways that you can keep yourself in action performing that function of ushering Wonder into the world via your activity. So it's not quite as passive as it would otherwise seem. There is a very active role that you or I consciously would be best advised to take or invent to do this job - simply - yet elegantly well and with an appropriate amount of energy - O.K.

I don't want to spend too much time arguing with someone in a traffic circle about who should come out ahead - because Wonder will be lost. I don't want to argue with someone in a supermarket because Wonder will be waiting in line - next to me. See, I don't want to spend allot of time arguing with myself about which telephone to buy or which pen to get because Wonder will be wondering why I'm taking so long to serve her right now and should it stay around. I need to choose the most appropriate form of utensils, instruments and behavioral styles such that wonder will be available to me to use directly. So my purposes will get increasingly more accurate, more economical, more appropriate to purpose. I will open up great vistas of time for its use and examination. And those contexts, like this, where there is a setting that has been created, that is being administered by somebody else, so that we can safely sit and learn from each person's version of wonder in themselves and examine the sensation of that experience of opening up the feeling - directly, safely.

(This is a transcript of a recording from the above cited workshop. It is typed in such a way to reproduce Mel Bucholtz's cadences as faithfully as possible.)

I'm sure you have all heard of 'Dianetics' in one way or another. I had heard of it a long time ago, but never really knew what it was.

A friend lent me the book 'Dianetics' by L. Ron Hubbard, and being of open mind, I read it.

Apparently Dianetics is a technology for ridding the subconscious (or reactive) mind of remembered pain or painful emotion. This subconscious painful emotion being what causes many of our day to day problems. Dianetics also professes that psychosomatic illnesses (illnesses caused by the mind) are also caused by these painful subconscious imprints (or engrams.)

The book spends about a page talking about how various psychosomatic illnesses including myopia and the other vision problems are normally cleared up as a matter of course by someone going through dianetic therapy.

Although the focus of the book is not on vision problems, it struck me interesting that the person who completes the therapy is called a 'clear' (clearness of mind => clearness of vision.)

"Dianetics" is of course wrapped up in Scientology which I do not know much about but am reading more and more.

I am a little leary about proclaimed quick fixes because usually when something sounds to good to be true, ... it is.

However, everything I have read sounds plausible so far. It is all built up upon apparently scientificly proven facts and the therapy has been demonstrated as workable in 100% of cases.

If anyone else has read the book or knows anything about Dianetics and Scientology, I'd be interested in hearing about it.

engrams are caused by thetans which are aliens that invade your body.
you can pay ron's mob 1000's of US dollars to certify your are thetan free
or some such nonsense. the principal apparatus of the scientologist is
basically a \$1.5 galvanometer which they will sell you for \$100+, that
measures skin resistance. of course you need an extended training course
to be able to use one of these devices which will set you back more arms
and legs. put in simple terms its an amazing hoax/tax evasion idea that
has gone out of control. stay clear of it... its *complete* crap.

I remember reading a bit about Scientology in the LA times. I think the founder was crzy-probably manic-depressive. But that doesn't mean there wasn't something to what he was saying. Since I get these clear flashes, I do think there is some sort of quick fix, I just haven't figure it out yet myself. Have fun reading. I think Lisa Marie Presley and Tom Cruise and some other not too stupid Hollywood types are into scientology. But I still say L.Ron Hubbard was weird.

<<snip>>

Whatever the merits or demerits of L. Ron Hubbard's theories, in practice it looks like scientology is using his theories to their own ends. To my mind, if you have to join a group to get results, there's something more going on than implementing a theory. I've taken several courses in meditation, and no one ever said I have to join their group or buy their equipment (of course, I did have to pay tuition, but I found that quite reasonable).

I can now practice meditation myself and "clear my mind" (although not at the point where it's affecting my vision)-: However, that can happen: I was at a talk by Jacob Liberman about three years ago, and someone in the audience asked him how he came to 20/20 vision. His response was that he was meditating one day, and in his mind's eye he saw the world clearly. When he opened his physical eyes, the world was clear!

My concern about groups like scientologists is that, consciously or unconsciously, they have a vested interest in maintaining your status quo, at the expense of your growth. Look at optometrists and ophthalmologists, maintaining that vision problems are genetic and you need ever stronger glasses! They may not consciously be promulgating a state that keeps you in glasses, but that's the end result (they're just parroting what they learned in school).

Sorry to ramble, but to me the bottom line is: if the theory is interesting, try it out yourself (and let us know the results, please), but be wary of

organized groups with vested interests.

Elena once recommended a fascinating book to me. It was called, "The New Primal Scream", by Janov. It sounds very much what you are describing, but in it he warns against 'copy cat' therapies and says that a third of all his cases are to treat people who have tried something similar (eg rebirthing amongst others) but with a couple of vital elements missing.

I don't know if Janov is correct, or if he was really the first, or if anyone else can do the same things safely, but I thought I'd point you in the direction of his book in the hope that you'll get to the 'real' story if there is one (and that you'll tell us what you find!).

Incidentally, I shouldn't worry about being suspicious of 'quick fixes'; according to Janov; it takes months of re-experiencing feelings that were repressed at the time when they should have originally have been felt.

And that reminds me, has anyone heard from Elena? I was wondering if she has disappeared to go to Janov's clinic.....she was hinting at needing to do something dramatic with the underlying things she had discovered about herself and I can't think of any other interpretation. If so, I guess she'll be gone for some time, but it would be great to know that she's ok if anyone has heard from her.

Caroline

'Dianetics' by L. Ron Hubbard

Apparently Dianetics is a technology for ridding the subconscious

(or reactive) mind of remembered pain or painful emotion. This subconscious painful emotion being what causes many of our day to day problems. Dianetics also professes that psychosomatic illnesses (illnesses caused by the mind) are also caused by these painful subconscious imprints (or engrams.)

I am a little leary about proclaimed quick fixes because usually when something sounds to good to be true, ... it is.

I have also benefited from this book. I have also found another of Peter's books, "Flower Remedies", (also published by Optima) very useful simply because it provides a discussion of emotional states from the perspective of a vision educator. There seems to be little discussion about the concept of "vibrational healing" on the Net, but it seems to be a subject which cannot be ignored.

Virginia,

You say that you wear sunglasses. This may be the reason for your cataracts. I quote from "Increasing The Strength of the Eyes and the Eye Muscles Without The Aid of Glasses" by Dr. R. A. Richardson, Kansas City, c1925 (Richardson was a contemporary of Bates and gives credit to Bates in his book):

:Most cataract cases have had many pairs of glasses and a large percentage
:of them have found comfort in wearing smoked glasses which, although they
:are very comfortable, greatly hasten the maturing of the cataract and may
:times result in blindness. As a result of closing out the normal light
:and robbing the tissues of the eye of their normal stimulation from it,
:the lens naturally becomes more opaque and vision worse; whereas, if no
:form of smoked or colored lenses had been prescribed, but instead the
:more recent treatment of building up the circulation of the eye by the
:proper use of undecomposed light and exercise had been used, nature could
:and would absorb the cataract and restore sight.

Also recall that the lens is very close to the pupil, which opens and closes to regulate light. It follows that if the pupil stops working, circulation to the lens suffers. And one more nutritional note: B vitamins are considered good for decreasing light-oversensitivity.

Thanks for all the input. My own reaction is negative as well... I
can't quite
explain why but something just doesn't seem right with 'Scientology.'

I have been reading the book "What is Scientology?" written by the
church of
Scientology and it appears to be a wholly manufactured religion.

Every thing seems OK except for a few "small" problems.

* god is never mentioned (although L. Ron hubbard is mentioned
everywhere.)

* they do not allow CIA, FBI or secret police members to be audited.

* The book uses obvious marketing and advertising techniques to suck you
in.

e.g. claiming to solve all your problems. Using 'perfect' looking
models
in all the pictures.

* they use Christian motifs (such as the cross) and concepts in various
places, but claim to be separate from all the other religions. In
short

it has the appearance of a Science, "shoe-horned" into a religion
(maybe
to gain tax-exempt status?)

* if Dianetics is so great, how come it is not in standard use in mental
wards etc.

I was grappling with whether or not to check out the church personally,
but I
couldn't figure out why my intuition was screaming at me. Linda's post

pretty much sealed it:

> Finally -
> - Even the church literature and technology states clearly that
> Dianetics
> and Scientology are not there for the express purpose of curing bodily
> ills. It is a religion, even if it *is* one of the most rapacious,
>ruthless
> vindictive, over-organised and grasping religions there ever was.
>Make
> no mistake. Dianetics is the tool of Scientology, and Scientology is
>a
> personality cult of the first order, with L. Ron Hubbard firmly set in
> the
> place of God. Do you really want to be a part of that?

and BTW, the friend who gave me the book is not wrapped up in
Scientology, he went there for a few classes but quickly discovered
that they would not audit him until he had taken many more classes
which he couldn't afford...

It's amazing where this search for clear vision is taking me... I'm
beginning to think it is my life purpose to find clear vision.

I've since checked out some of the stuff on the web, and I am staying away from scientology. I had a feeling (intuition) that something was not right about it from reading the book, that is why I checked here first...

Thanks for your input.

I'm curious, what did obtaining the state of 'Clear' do for you? Did you get any benefit from it at all? How much of Dianetics is really true?

I am staying away from Scientology, but I am just curious.

Art, So glad to get your reply. Not sure of the date of that Time
article. Pretty sure it was June and it may have been June 6, 1994.
Maybe Time has an archives on the web. They're sure to have a website;
why don't you contact them? By snail-mail, if not on the web.

If you hunt around on the web long enough about Scientology, you
will probably find a mention of it. Might even be mentioned on the
newsgroup "alt.religion.scientology". I have been lurking there for a
long time - but I NEVER post there... - M.

Is this really your first contact with "Dianetics"?
Do you know anything at all about Scientology?

That book is the "bible" of the cult of Scientology, whom Time Magazine called "The Cults of Greed" and who do not have a very good reputation.

I have read "Dianetics". Anything I've ever read coming out of Scientology has sounded like so much double-talk to me.

They have spent the last 18 months of so spamming the newsgroup "alt.religion.scientology" with hundred of messages a day from apparently fake I.D.s, all in order to shut the newsgroup down. Scientology does not seem to want people to be heard who oppose them.

If your friend is, in any way, involved with Scientology, I would be extremely careful. If he isn't, you would be doing him a favor to arm yourself with unbiased information about this group.

I would be very cautious about anything connected with Scientology. They don't have a very good reputation, and that's putting it mildly.

Here are some useful websites:

Hello all!

There are a great many subjects about which I know absolutely nothing, and on these I am quite content to say nothing at all. Dianetics and Scientology however are not in this category. Though it may get me in some considerable hot water, I have to comment, or else I am not doing my duty as a participant in I_SEE.

Art Blake wrote:

>
> I'm sure you have all heard of 'Dianetics' in one way or another.
> I had heard of it a long time ago, but never really knew what it was.

I was an active member of the Church [sic] of Scientology for about 3 years, and a fringe member for another 2 years while I was extricating myself.

>
> A friend lent me the book 'Dianetics' by L. Ron Hubbard, and being
> of open mind, I read it.

As did I, several times over, for the very same reason.

A fair summary, though you might add that the Dianetic technique,
known as "auditing" has as its aim the eradication of the Reactive
Mind. Not a bad idea, if you accept the fundamental premise.
But read on...

>
> The book spends about a page talking about how various psychosomatic
> illnesses including myopia and the other vision problems are
> normally cleared up as a matter of course by someone going through
> dianetic therapy.

That is the claim at least. It is not true.

>
> Although the focus of the book is not on vision problems, it struck
> me interesting that the person who completes the therapy is called a
> 'clear' (clearness of mind => clearness of vision.)

Usually capitalised as a noun to refer to a person who is clear. I am
a Dianetic Clear, and still am, though I am no longer a Scientologist.
I completed their program in record time, and was a sterling member
until I began to see it for what it really was.

If you are looking for a way of improving your vision, you couldn't pick
a longer and more expensive way to go about it than to get involved
with...

>
> ... *Scientology* which I do not know much about but am reading
> more and more.

Try...

alt.religion.scientology (NG)

a VERY free-form Newsgroup for critics of the organisation - fasten
your
seatbelts folks! See also...

<http://www.tiac.net/users/modemac/cos.html>

a good Website, with references to other sites of interest, including the PRO case.

>
> I am a little leary about proclaimed quick fixes because usually when
> something sounds to good to be true, ... it is.

This is definitely the case here.

>
> However, everything I have read sounds plausible so far. It is all
> built up upon apparently scientifically proven facts and the therapy
> has been demonstrated as workable in 100% of cases.

Not so unfortunately. A) it is no more scientifically proven than most of your better pop-psychology books and B) 100% of cases is simply not a fact in practice.

>
> If anyone else has read the book or knows anything about Dianetics
> and Scientology, I'd be interested in hearing about it.

I know a very great deal about Dianetics and Scientology. I view my experience with them and their technology in the same way that a victim of a particularly bad car crash might; I spent a fair bit of time in and out of a coma, I hurt all over for a long time when it was finished, and I still walk with a bit of a limp. But when all is said and done, I think I'm a stronger person for having survived it, though I wouldn't like to go through it again, not in a million years.

Furthermore -

- Dianetics and Scientology will do nothing to improve your vision.
If

you don't believe me, go into your local Scientology org and ask if there

are any Clears who wear glasses, either on staff or as public. When you meet them, ask them why they wear glasses if they are Clear. Wait patiently while they fumble for an answer. If you are not 100% satisfied with their response, turn right around and never go back. I promise you you will not get a straight answer.

- The fundamental lesson I learned from Dianetics was something I could

have learned in almost any other way; *that I had the power to control

my own mind and emotions any time I wanted, only I didn't know it.*

- If you get involved in the Church proper, you can expect to lose every

cent you have, but if you don't, it won't be because they didn't try.

No matter how smart you are, you have to remember, these guys do this for

a living, and there is no trick they don't know when it comes to getting

money out of people. Leave your wallet at home if you go in, or better

yet, stay right away.

- There are some good people involved, and your friend is probably one of

them. But a misguided group with nothing to offer but hope and promises

is still a net waste of time and money, no matter what they profess.

Finally -

- Even the church literature and technology states clearly that Dianetics

and Scientology are not there for the express purpose of curing bodily ills. It is a religion, even if it *is* one of the most rapacious, ruthless

vindictive, over-organised and grasping religions there ever was.

Make

no mistake. Dianetics is the tool of Scientology, and Scientology is

a

personality cult of the first order, with L. Ron Hubbard firmly set in the

place of God. Do you really want to be a part of that?

Art, mon cher ami, I wish you well. But save yourself a lot of time, money and

heartache. Thank your friend for his concern and drop the subject while you

still can.

- Linda

Linda,

Thank-you for very clearly pointing up the risks and dangers of Scientology.

I have never been in Scientology, but friends of friends have. If I had been, I couldn't have said it better myself.

So glad you got out of it with a whole skin.

You have my great admiration and respect.

Please this is not a dianetics group!
This is a vision/eyesight group. Other modalities
can be introduced but let's stick to the topic. What are specific ways vision
and eyesight can be enhanced? There are so many helpful techniques
from vision therapy, natural vision improvement and Bates that are full
of spice and interest. I think it is great that web sites and referrals are
made to
other sources but lets keep to the topics Alex started I_see with. Thank
you for my opinion.

I would disagree with the comment that my eyes are misshaped...since I sometimes have clear flashes.. I think its more likely that my eye muscles are chronically tense.

I'd have to say that usually my dreams are pretty clear, but sometimes blurry. Occasionally my dreams are extremely brilliantly clear.

I'd further like to apologize to the list for wasting your

bandwidth with the 'rash' of Dianetics messages.. I didn't expect to uncover what I did and truly thought Dianetics could potentially be useful for improving the vision ...

a little embarresed but glad to now be educated.

So he has clear vision. Do you mean "internally clear vision"? If yes, then what you are saying is that having a clear 'inside' vision, what the Extreme Emotionalists (like Elena) and most wholistic healers (Lieberman, Kaplan, Goodrich, etc) think is what determines the external (or physical) vision, is not enough to restore external vision to clarity.

Of course, if you mean "externally clear vision" you are blabbing nonsense.

To save some time, here are your answer options:

a) I was wrong. He doesn't have clear(internal) vision.

b) He has clear (internal) vision. But there is a lag between getting one's inside vision clear and then one's physical vision clear. Now that he has clear inside vision he needn't do anything (except maintaining it), clear external vision will just come in time.

c) Why, the hell, do you care about external vision? It's only the inside vision (i.e. the "soul") that matters.

Let's assume that Art has a clear inside vision and that you don't think b) is that right answer. What should Art do to correct the shape of his eyeballs? I agree with you that the physical evidence of his myopia is most likely in the form of elongated eyeballs.

Hi Art:

>> I'd further like to apologize to the list for wasting your bandwidth with the 'rash' of Dianetics messages.

Don't be silly. You were sharing information that appeared helpful - and the last thing we need is for folks to stop sharing things.

As I posted a while ago, I know two people who had eye problems (macular something-or-other) wherein they awakened to see only blobs of grey, and ophthalmologist after ophthalmologist said that the situation was irreversible and there was no hope of recovery. The first man (my uncle) gulped beta carotene and vitamins C and E - and, to the total shock of his ophthalmologists, his vision returned to normal. (That was ten years ago, and he is still fine ... reading, driving, et cetera, without any problems.) The second guy experienced this about two years ago. He, too, was told that the situation was hopeless, and that there was no chance of recovery. But my uncle plied him with beta carotene and vitamins C and E, and his vision returned to normal (to the complete shock of his ophthalmologists); he still sees fine, and can read the "Times" without glasses, et cetera. This certainly isn't "medically proven", but I shared it with the list just in case it was of help to anyone.

In short, you've educated all of us, which was a big favor in itself. I'm sure I'm not the only one who had hitherto known very little about dianetics. Now I know to run from it.

Thanks again.

Best regards,
Virginia

I am really curious what you think the distinction is between "internal"
vision and "external" vision?

as for what to do about mishaped eyes, well I have written an entire FAQ on
the subject and I dont really have the time to rewrite it in this small space.
feel free to check it out: www.cia.com.au/vic

vision is a complex beast, so complex in fact that modern science can
say little as to why you see, why you see forms and shapes and colours and
how these come about to be experienced in the theater of consciousness.

consciousness is seen by some as the "last frontier" of scientific endeavour.

now to me the above question was a bit strange, because there is
no real distinction between external/internal vision. all vision is projected
in the same conscious space. external supposedly comes from light hitting the
retina generating form and colour etc information which then works
its way in to the various brain centers which we experience as sight.
so called internal vision supposedly originate from the brain and is the routed
through the visual centers which we also experience as sight. there are
of course clues (like intensity etc) so that we can tell the difference
in origination, otherwise we would all be living in dreamland.

myopia is a lenghtening of the eye ball which projects an out of focus image
on to the retina, which in turn transfers less information into the
brain and into consciousness. the brain extrapolates the missing bits
giving everything a nice soft quality. a bit like a playboy centerfold.
this of course doesnt help if you need to read small print at a distance.
but it does help if you find the world overbearing or too intense.

this brings up the point I wanted to make, if your own internal projections,
ie what some call "inner sight" is blurred what chance do you have to have
clear external sight if "external" vision is passing through some
nice soft focus filters on the way to conscious experience, ?

from my experience modern medicine (there are exceptions) is very keen
to disassociate the mental from having direct influence on the "physical".
placebos for example are looked on as almost a nuisance. and the fact
that the doctors attitude when prescribing placebos plays a crucial role
in the results is also seen as either "statistical error" aberation or

just hypnotic suggestion and not something worthy of further scientific research, leaves me shaking my head. the fact remains the mind is capable of extra-ordinary feats, include seemingly the impossible. for example there are documented cases of multiple personalities where one character is myopic and others have perfect vision. now we are not talking here about "internal" soft focusing filters deep inside the brain we are talking images not focused on the retina. ooh aah I hear you say, is it done with smoke and mirrors? an another clue is that under general anesthetic patients develop incredible flexibility include arthritic patients, who normally can not bend joints, we find that when "out cold" the joints do indeed bend. why is it so? simply the mind/brain keeps a "pattern" of nerve firing to keep the body upright in its never ending battle against gravity. that pattern (the technical term escapes me) includes strange things like arthritic battles in the joints, or over tense or loose muscles around the eye. in other words part of a persons "persona" is a dossier of nerve response and activation patterns. these in turn mould and shape the bodies tissues, which in turn affect the patterns. ie complex feedback loops. who or what is responsible for all this? clearly yourself, your awareness is what programs your brain and body, or sometimes your lack of awareness, sometimes its at the forefront of consciousness sometimes its very dim. somewhere along the line from having had clear vision to the present, your mind ie you made decisions which have changed the way you see the world at large. and under the circumstances you were in at the time it was surely almost inevitable. so lets summarise. in a word: responsibility.

numerous factors have influenced your mind one way or another into letting your sight become short or long. for example, stressfull adolescent years could have seen you add some nice soft focus filters. excess near work can have changed the nerver firings causing eye mucleles to lenghten or shorten in turn altering over years the "at rest" shape of the eyeball. etc etc. etc. etc.

now clearly you have ended up on this list because now you have decide consciously that the state of affairs you chose back then is no longer appropriate now. you now want to see clearly without the aid of those optometrical devices plastered to your face. how do I do this? is it possible? how much improvement is possible? will it last?

well the answer is yes improvement is possible. improvement comes quickly at first then slows down. and yes it can last.

lets quickly look at the various layers.

again its been a while so the technical terms escape me.

physical mopia: comes in two basic flavours. 1) functional(?). early in the morning you will find your sight is at its clearest, by night its less clear. this is temporary myopia. you muscles are tired, you brain isnt firing as much. you just dont see

as much as you did first thing in the morning. this pattern also manifests itself over periods of heavy near work. read like a mad thing and your eyes adjust to the workload easing the load on the muscles by nicely lengthening your eyes for you. your body is extremely cluey. :) problem is sometimes you are not. :) keep this up and the tissue is going to grow into this nice usefull shape for close up work. not usefull for driving cars however. remedy: STOP IT. take lots of breaks, vary your visual worload. china teaches small children basic eye care the result is the lowest rate of myopia in the world.

2) structural myopia, is where you didnt head my advice and treated your eyes like microscopes for years, peering at small print in hefty tomes. ok so now your eyes are a funny shape which you find less then satisfactory for reading street signs in your car at 100km/h in the dark. fixable? tough call. but not totaly without hope. lets be honest, its going to take a long time for your eyes to grow back into a more general purpose shape. before you embark on this route, you really need to ask yourself, do you have the determination to spend as much time and effort as you did to get to where you are now, to change the very structure of a very complex organ? we are talking years here. for most people the answer is no. most want the quick fix, the magic pill, the fast laser or instant scalpel. undo years of ingrained unconscious habits with a couple of overnight miraculous exercises? forget it. it aint going to happen. you will need the kind of patience involved in wearing away a mountain with a cloth by stroking it once a day to get real results. there are a truckload of good books out there that explain what you need to do to go down this route.

mental myopia. this in itself is a complex beast. and I cant really separate it from the above. I am talking about mypoia within the very core of your being. a lack of clarity or desire for less clarity. a desire for withdrawal or simplification or avoidance of pain. there are so many variations on the theme in the mental realm, I cant do them justice but have to lump them under a single heading. do you really want to see clearly? can you cope with the added detail and intensity that comes with sharp vision. does the extra detail equate with ugliness or beauty? or you hiding from the world or do you want to participate and experience it fully, with all its beauty, love, pain and grief? its no good deciding that you want clearer vision if your mind is full of counterproductive habits that will work against your newly found determination. you must really get to know yourself and your mind and work to eliminate poor habits and limiting beliefs that no longer help you. you have to get to know both the intelectual and emotional side of you that may have an impact on your sight, both physical and mental.

here is an example, people have very complex personas, some people project a confident educated strong character, but deeper are insecure. these people may find they need the external support of glasses to give them "real" support to justify clarity. they want to be clear and sharp but dont think they can achieve this themselves. no amount of work is going to keep this person out of glasses, without first some

deep confidence boosting. another person may have had a traumatic childhood and reduced the information from the external world by softening it and pushing it away. this person may not even want glasses but cant get do ordinary tasks without them. this person simply isnt interested in having the external world assert itself into his or her domain. without first bringing this person out to want to interact with the world at large, to want to drink from its limitless variety and intensity, sight just isnt going to improve, is it?

anyway there are probably as many variations on the theme as there are people :) human beings are vastly complex creatures, with numerous physical mental interacting feedback layers. the mental aspect ultimately, within the confines of the physical restrictions determine how, who and what you are.

anyway I havnt posted for a long time and have gone on a bit, but I hope I have cleared things up for you a little :)

I have been reading the articles about Baby mode and Bates method, and have started to practise some of the methods suggested. Last week, I decided not to wear my glasses for a period of time to see what would happen. I found that I felt tire more easily. I am a teacher and a part-time editor. I spent about 8 hours today on paper work and have experienced very frequent eye strain. Should I wear my glasses when I am working?

Funny you should ask... I have been having dreams where I could suddenly see with crystal clarity and without effort. And not just clear flashes, but sustained clear vision, with heightened sense of awareness. This has started in the last couple of weeks, as I have gone without contacts or glasses (I had been wearing reduced perscription disposable contacts -3.50). I haven't noticed any great improvement in my waking vision, but it is wonderful to be able to read and use the computer without any lenses. I am taking it as a good sign....

We all have clear internal vision, the problem is that most of have forgotten. The process is to remember why we are here on Earth and bring that clear vision into our daily life. (Clue: I believe we are here to help others and therefore ourselves to remember how to unconditionally connect from the heart and serve.) Then the eye and its structures can remember their perfect shape to hold the brilliant clear flashes of perfect 20/20.

Elongated eyeballs, in my experience, is the inappropriate practising of looking from the mind of an unclear purpose (Vision). The nerves and muscles of our body respond to the energetic vibrations of our thoughts and mental impressions of who we think we are. They also vibrate with the Soul knowing of who we are. It depends on which of these two we practise on a daily basis. I use my vision therapy activities to remind me of mySoul truth and bypass my ego gratifying and addictive patterns of seeing. Then my near Presbyopic eyesight sharpens up to about a 30 year old. I am much older! The clear flashes of nearsightedness is a similar process in reverse, that is at twenty feet.

A few of my autumn thoughts, thanks
Robert-Michael Kaplan

I'm still very much lost about these clear flashes. If my eyes are so misshapen, how is it possible for these clear flashes to occur? Something has to change instantaneously, and I can't imagine my eye length suddenly getting that much shorter, then longer again. And Linda Wright's experience at such a high level of myopia. Those flashes have to be, I think, either muscular or neurologic in origin (and I think some sort of energy state may be behind it all). So has anyone really monitored people who are getting these flashes to determine what the mechanism is?

GREAT questions, Julie! Although this is veering off the thread, it's a very interesting topic. Bottom line is that I am exactly where you are, wondering what changes for a brief instant and then snaps back to its prior state. Today's realities leave me with little time for high-quality thinking but here are three possible explanations:

1. Neurologic. There is an optimal level of stress. The brain functions best at that level. As today the stress level is often higher than optimal (with the individual often unsuspecting), a relaxation reduces the stress towards optimal and improves brain signal processing. An assumption is that the brain tries to maintain the right focus/clarity (this is mute... touches on the cold turkey vs the 20/40 stimulation issue) . Memory of how things should like helps, if present. When the state of true relaxation is gone, the clear flash is gone.

2. Muscular. In the very short term this involves only the ciliary. A reduction in stress or near-point focusing effort causes a relaxation

of the lens which could induce up to about 2.0 D decrease in refractive power, thereby alleviating myopia. This doesn't seem an especially good explanation.

2. Wholistic. The eye is in not misshapen. Through avoiding your true(real) self you have lapsed into (false) myopia as a way of escape and sealing yourself off from reality. During a clear flash you connect with your true self but fear of the reality and responsibility scares you back into the blurred state. Your mission is to overcome that fear and reunite with/rediscover your real self.

Note that the wholistic explanation seems least flawed, although, *in essence*, it is the same as the dianetic preaches. However, cadaver eye studies as well as ultrasound measurements in live eyes prove that myopic eyes *are* longer. Being kind of a schizophrenic ;) I can relate to all the explanations, but think I know to a great extent who will like which one. My position is that in the case of clear flashes the driving force is psychological. I am interested in what others have to say. My knowledge of neurology is very limited.

as far as I am aware no one has ever done a study on clear flashes
although I tried volunteering for one once. put into perspective your
eye is 1mm too long for every 3 diopters of myopia. thats not a lot
of change required for a clear flash to occur.

MSM - Methylsulfonylmethane (CH₃SOCH₃)

I went to a seminar last week and discovered MSM. The substance is classified as a food. MSM is supposed to help cataracts, dry eyes, floaters and other things not related to the eye. I have been using it for a week now and have noticed that my eyes are less red than usual and more lubricated during the day. I wear hard contacts so lubrication is a must.

I also have floaters. I just leaned back to try to detect them and I could find them. At the moment they seem to be less noticeable.

I have a friend that does not wear glasses but does have difficulty seeing things close up. She says words appear to swim. She tried the drops and reading a map was not a problem to her. She usually has to turn the map a little to focus in on it.

My point is, I would try the drops first, before I do any surgery to remove cataracts.

You can get the drops from "JoAnn & Dave Health Products".
800/700-5402.

I don't wear contacts, have no problems with dry eyes, and
don't even know what a floater is ... but I do have
cataracts <sigh>.

Is anyone else on this list familiar with MSM? It sure
sounds fantastic!

No appology necessary, as far as I'm concerned.
I learned something about that Dianetics stuff
and it's cult from the exchange.

That's it, very well said! Reducing myopia naturally is a long process, which regardless of means - spitual only, plus lens, or combination thereof - should bring about the reduction of axial length. If the refractive components of the eye are miscorrelated, there is no way to get around it, let's not fool ourselves. The brain can certainly interpret some blur, but there are limits. Note, it took Antonia Orfield seven (7) years to nearly eliminate her 4.0 D myopia, using mainly lens control. It took Linda Wright six years. We are generally speaking about this neighborhood, given strong commitment. The nasty thing is that usually for every two steps forward we make 1.5 steps back. The effect of an eye-relaxing weekend is quickly unwound by the visual demands of the workplace. Ideally, one should look at the screen/book so corrected that the print is slightly beyond infinity.

Imagine doing that at work - one wouldn't be able to see anybody. How I tried to resolve this problem will be the subject of another post. Using the plus lens therapy and related techniques raises another question: Are we getting hooked for life? As I mentioned about two months ago, holding gains is largely psychologically controlled and requires "upgrading" of the personality.

When I am speaking about internal and external vision, I refer to these terms from a wholistic standpoint. Liberman uses "inner", and "outer", Kaplan may be using something else.

Internal vision is the feeling of the degree of unity with one's true self (=God), the sense of purpose, direction, and meaning. At its desirable level, internal vision equals harmony, or, the way I prefer to put it, Contradiction in Dynamic Equilibrium (a bit of a mouthful but I find it better).

External vision is simply the physical vision, i.e. the eye as matter, the brain, etc. You are trying to get a distinction between internal and external vision within the physical realm. There may be some, I am not a neurologist, but that was not my point.

As to your last post on the clear flash mechanism, I think 1 mm is too much to expect that the eyeball suddenly contracts (that much) and then springs back. Note that the cornea, which accounts for roughly 2/3rds of the eye's refractive power is about 0.5 mm thick. Of course, the tissues are different but I really don't think the eyeball is that springy. Also, consider the speed/acceleration, clear flashes come and go in an instant. To me, clear flashes still remain a mystery.

To recap, the quest for clear vision is a long process (years) that includes (re)discovering one's true self *and* bringing eye components into correlation.

Informed Behavioural optometrists use an instrument called a retinoscope to evaluate the changes in retinal light reflection when the patient experiences change in thinking. The light changes are a print-out of the patient's thoughts, beliefs and inner clarity. I have personally used the retinoscope to observe changes when the patient has a clear flash. The retinal reflex brightens up. At the same time there seems to a brighter expression in the patient's eyes. I remember Optometrist John Streff reading this retinal reflex like a lie detector test. He would ask the person a question and then study the reflex and know if the answer was true, by the intensity and motion. A clear flash in my opinion comes from the mind and does not occur as a result of a linear change in the eyeball. The mind

change is a hyperopic or farsighted perceptual shift in thinking and consequent projection through the eyeball that remains myopic. A Kaballah reminder says: *You can only see what the mind projects*

I will be travelling for a few weeks to England and will check my e-mail after the 5th November, 1996. Enjoy the changes in season. I love the yellow/orange leaves. It awakens my retina.

Robert-Michael Kaplan.

Why not? The muscles that surround the eye are clearly capable of moving very quickly - the saccadic movements can take place in 1/50th of a second. If the dynamic equilibrium altered in the correct way, then the eyeball could be squeezed or released thus altering its shape. The problem is how does the correct way happen? The recent reports of Elena and Linda Wright look very promising.

Whilst on the subject of muscles, have you noticed how close the muscle that controls the upper eyelid is to the obliquus superior (one of the muscles that Bates reckoned controlled accommodation) Perhaps this accounts for the success with blinking that Adam Klein had.

<SNIP>

The failure of mainstream ophthalmologists to investigate such reports is very depressing. Even if they did it to prove that it's only in the imagination (which I don't believe)

More background here: Jacob Raphaelson, O.D., who practiced in the beginning of the century, wrote several books in the fifties and sixties extolling the virtues of "plus-one-spherical" glasses, that is, glasses that "correct" for one diopter of farsightedness, or, put another way, allow the eyes to focus one diopter less, optically simulating a distance environment. He said that the use of plus one spherical glasses by all for all close work would eliminate myopia. In addition, he said they could be used instead of tinted glasses to improve the eyes' tolerance of sunlight. He said this is because of their "decongesting" effect on the eyes.

Anyway, to answer your question, most plus-one glasses that they sell in stores are plastic. At least that's true in the US.

Dear friends,

Recently one of my friend (Navin) of Jamuguri near Golaghat have got eye injury due to a bomb blast which made him almost blind. Later, from the treatment at Sri Sankaradeva Netralaya and also in Apolo Hospital, Hyderabad his eye sight is improved to some extent. One doctor at Apolo Hospital mentioned that his eye can be treated more effectively with a machine ... so called 'caratoprothesis', which is not set up in their hospital. So if any one of this field can assist any sort of help, please inform. May be there is any treatment available in US (he is ready to go abroad for treatment).

Thank you.

Babul

The report of Sri Sankaradeva Netralaya, Guwahati, India is:

Clinical Diagnosis

Ciliary staphyloma - OD
Retinal corneal multiple foreign bodies - OD
Corneal lucoma - OD
Neovascular change in the cornea - OD

Conjunctival scarring - OD

Dry Eye - OD

Phthisis bulbi - OS

Vision Progress

- To: i_see@indiana.edu
- Subject: Vision Progress
- From: cheryl_lee@rdrorl.com
- Date: Thu, 24 Oct 96 14:07:38
- Sender: owner-i_see@indiana.edu

Hi Everyone,

Just wanted to drop a progress report to everyone and possibly help with any general support and motivation.

1956	school told my parents I needed glasses - 8 yrs old, refused to wear them
1963	started wearing hard contact lenses
1970s	did yoga eye exercises - no apparent changes
1980s	did Bates - no apparent changes
1990s	started switching between contacts and glasses started doing specific emotional release work

I have always felt that if my vision got worse it should also be able to get better - somehow. If you could fix everything else - why not your eyes? I could never find an optometrist who could help until ...

old prescription	R	-4.75	-2 axis 90	L	-6.50	-1 axis 15
2-12-95 Dr. Sirota	R	-3.25	-1.50 axis 90	L	-4.00	
12-1-95 Dr. Mancini	R	-2.75	-1.50 axis 90	L	-3.50	
6-7-96 Dr. Mancini	R	-2.75	-1.00 axis 90	L	-3.50	
9-5-96 Dr. Mancini	R	-2.75		L	-3.00	

Dr. Sirota is in the Chicago area. Very brief description - He determines your prescription thru a long unconventional exam that primarily consists of trying on different lenses and asking you how does it feel. The exam was very emotional for me.

Dr. Mancini is in Concord, New Hamshire. He determines your

prescription by having you try on lenses and he feels the energy fields around your head - my interpretation. He determines the clarity your body is emotionally and energetically ready to deal with. His prescriptions do not cause any stress in your body, consequently it can shift easier.

My path has primarily consisted of wearing no glasses or training glasses 95% of the time. The other 5% consists of nighttime driving when very dark or raining. I see a doctor monthly who does traditional osteopathy which is similar to cranial-sacral work. I have done rolfing, breath work, defusions, massage, yoga, eye exercises, relaxation, a workshop with Dr. Kaplan, any other various energy work. I am starting bioenergetic work next Mon. I totally believe my vision blur is emotional. My astigmatism (vision distortions) have disappeared. I use pin hole glasses and play racquetball regularly (very well) without glasses or with my training glasses. I am very health conscious food wise as well - macrobiotic, vegetarian, and whole foods. I am currently doing a body/colon cleanse this week and plan on trying the coffee enemas this weekend. They are supposed to be very good for cleaning the liver which affects the eyes according to Chinese medicine.

Well, I think that is all I wanted to say about my vision progress right now. Thanks everyone for your discussions. It is good to know I am not in this alone.

Later, Cheryl

PS: I have done computer programming since 1970, licensed massage therapist (1991), Three In One Facilitator (1991), flower essence practitioner (1992). I am now attending Dr. Michael Mams School of Healing and Enlightenment in San Diego - hands on healing stuff. He used to be with Barbara Brennan.

Hi all,

Does anyone have any hints for someone who just got their first pair of reduced lenses.

I have been wearing them for two days now and at night I find that my eyes are just really tired. I must admit that I don't palm during the day and when I try to do work at night but my eyes get so tired that I end up giving up.

I also have noticed that my eyesight is alot better during then day when I am outdoors rather than when inside or at night.

My eyes get tired too. If they are relaxed for distance vision and just passively receiving an image, I don't understand why they get tired. Any ideas?

Hello all,

I want to think with you all about what the problem actually is. What can you really say about seeing problems?

If you take the problem very simple, you could say that our eyes are out off shape.

So the light that comes in, misses the right direction, it doesn't find the point where it get's absorbed the right way.

Isn't it very simple, that our being just "hangs" to much in our enviroment, and by that our eye is out off the right shape?

And when we look at the sun, this big aggressive light, so that it makes our being to go back in our selves?

And because off that we get the right shape back and see suddenly clear again?

Aind the problem just that our being hasn't got his right place, in our selves?

Because off misunderstandings in our enviroment, we lost the balanse between our selves and the enviroment.

And this finds his plase in our eyes, where we 'lean' to much to the outside.

Aind it just that simple?

The balanse between our selves and the enviroment, and our eyes that stands between these two.

Aind the answer, getting the right balanse back?

And is our 'leaning' to the outside not caused by, not holding on to our selves, in some kind off way?

To solve our problems, we have to get the right balanse back.

By getting back into our selves, by getting out off our enviroment.

Whatever the method is, it will come down to this.
I hope i've giving some off you insperation.

Go without any lenses as much as possible. Then when you put the reduced back on, you can see better than without any lenses.

I think it took me at least a week to get thru the tiredness. I did do more eye massage. I have never been a big palmer. I do look out the window a lot and relax my eyes that way - with and without glasses.

>I also have noticed that my eyesight is alot better during then day
>when I am outdoors rather than when inside or at night.

Yes, that is true and will be until ...? My clear flashes occur mostly outdoors in the sunshine. I can see so well then.

Are they really relaxed? How do you tell? One's perceptions are not always accurate.

I understood Bates to say that if your eyes are relaxed and you are not straining to see, then you will see perfectly. The difficulty is in knowing how to achieve such a state :-)

Peter

RELAXED AT DARK FOCUS, NOT DISTANCE

I'd imagine that there are a great many causes for visual tiredness (asthenopia?) One that I subscribe to is the idea that your eyes are relaxed when they're focussed at your "dark focus" distance, also known as tonic of accommodation or "TA". This is where they focus when you're asleep, or your eyes are shut, or you palm. This state is a neutral balance between the EFFORT to focus close and the EFFORT to focus far. When you make an EFFORT for a long time, you get tired.

SLEEP IS RELAXED -- SO ARE EYES

I don't believe any of the conventional wisdom about "relaxing"

being the same as seeing far. Sorry Bates. I think your common sense will tell you that you're relaxing while you sleep, and your eyes usually do too, and they don't focus for distance when you're sleeping!

MEASURE YOUR DARK FOCUS (TA)

You can measure your dark focus by seeing at what distance you can see clearly when it's very dark. You may have to wait a bit for your eyes to dark adapt first.

Your TA (dark focus) distance changes after looking at a certain distance for a while, but then it gradually recovers to where it was before.

USING TA TO SEE CLEARLY

You can use this as a trick for seeing clearly further -- look as far as you can clearly. Shut your eyes. Wait a few seconds, and open your eyes again. Your eyes will "start" their focus attempt from the TA of the moment (not yet reverted back to your normal TA) and be able to focus a bit further. Repeat.

ADVICE ON TIREDNESS

As for constructive advice on visual tiredness, I'd say "vary your accommodation" in order not to get tired. Put on your minus glasses now and then (even to read or see the computer), put on (or take off) plus lenses now and then too. It's the same as if you sit in one position for too long. You need to get up and stretch now and then.

DARK OR "OPEN LOOP" VERGENCE

Incidentally, there is a parallel to TA for vergence, as well. Your eyes don't necessarily point in the same direction when you shut them. You can see this by doing a trick I first saw in Kaplan's "Seeing without Glasses" book as the "two-eyed patch" on page 95. You can do this with one hand, using 3 or 4 fingers held in front of your nose, blocking the "common view" between the eyes. You shouldn't be able to see any point from BOTH eyes if you're doing it right. Now your brain has no info to use to figure out how to line up your eyes, so they drift. It feels good. Now yank your hand away and you'll feel your eyes snapping back into a unified view of the world again (back to vergence). You might feel a strain here.

strange clear flashes

- *To:* i_see@indiana.edu
 - *Subject:* strange clear flashes
 - *From:* "Art Blake" <art@blakesys.com>
 - *Date:* Mon, 28 Oct 1996 14:20:07 -0500
 - *Organization:* Blake Systems, Inc.
 - *Reply-To:* "Art Blake" <art@blakesys.com>
 - *Sender:* owner-i_see@indiana.edu
-

It seems like my clear flashes are getting more and more frequent...

But they are strange. Let me describe:

I see a double image .. in both eyes. Of the two images in each eye, one is clear (very close to 20/20) and the other is blurry (around 20/200-- about what my vision is when I am not having a clear flash.)

With both eyes open, I see a total of 4 images which are at slightly different angles from each other, two of them clear, two blurry.. they combine to make a sort of "hash" of the image.. ...

These "clear flashes" usually occur after a blink, and then hold for a few seconds.. or until I blink again. Sometimes they occur spontaneously.

I can make them occur at will.

While riding in a car on a sunny day, if my glasses are removed, I can actually clear up street signs 100+ feet away at will- but there is usually this 'quad image'.

Occasionally, I have a short clear flash that doesn't have the blurry aferimages... but this is very rare.

I've forgone my glasses completely since last Friday (today is Monday and I'm still going!) and I notice that my vision is yet even clearer.

I wish I could go all the time without glasses, but it is so hard to do with my work & travel ..

I've also been fasting since last Thursday (you might recall a post a few months ago about wanting to try this ..) and I think that has helped clear my vision a lot ... it has definately increased the incidents of "clear flashes"

any explanation for the quad image??

Any other experience of this product? If it really works it would seem to me to take away the need for a whole host of the things that we do to improve our eyes. I knew about the benefits of far and near focussing to prevent presbyopia (or whatever it is called), but not for general myopia.

Any thoughts appreciated.

Caroline

Hi Caroline,

[snip]... Kedalene who also bought the Vision Care equipment has confirmed definitely definitely that her vision has improved tremendously after using the Vision Care equipment. In the past, she had problems looking for her friend at the MRT station. Now she has no worry about looking for her friend as her vision has improved and she could see much sharper and clearer image. In fact, now that she could see much better she is beginning to be lazy doing the eye exercise. But of course she knows she has to carry on to have perfect vision. She had over 600 degrees on one eye and over 200 degree on the other (before she embarked on this eye care programme). We bought and collected our equipement on 8th August and that means just 2 and a half months and you see tremendous results.

[snip]...My sister called one day and was panicky that her daughter (6 years old) has a lazy eye. She wanted to take her to the specialist immediately as she is afraid that the lazy eye will get worse when she starts school next year. I told her all the specialist would ask her to do is to use an eye patch which kids don't usually like as it restrict their

vision. I told her to come over to my place and try the equipment I bought. She came immediately and I let the girl read the eye chart before using the equipment. The good eye could read up to the second last line. The lazy eye could read up to 4 lines above the good eye. After using the equipment, bravo!!!! the lazy eye could read all the way down to the same line as the good eye. It was amazing, my sister asked that she take my equipment home while I buy another one for myself. A few days later I called her to checked if the lazy eye has begin to "work". She said the lazy eye can see as far down as the good eye now even without using the equipment. In fact, the little girl is lazy in using the equipment now that she could see. Marvellous, isn't it. The equipment works on the principle of strengthening the eye muscles by stimulating it to focus far and near. Simple but it works.....

No Cheryl, you didn't miss anything. I don't actually know any more than what you've seen at the moment.

But if you are interested I can go back to my Singaporean colleague and find the company/price details. I was just wondering before I did that whether someone on the list would tell me not to bother due to prior experience.....

Caroline

I must have missed this. What is it? How much is it? And where do you get it?

Cheryl

Apparently someone invented a 'REFOCUS VDT Mover' that has the purpose of relieving visual stress by varying the accommodation. You can do it a lot cheaper by moving your head in and out or by swapping glasses as I suggested above, but I can see how an automatic system might be useful.

This is from URL:

<http://research.opt.indiana.edu/AA095PB/MonPM/MonBVPOP.html>

REDUCTION OF VDT-RELATED ACCOMODATIVE
STRESS MEASURED BY DARK FOCUS OF
ACCOMODATION - THE "REFOCUS" SCREEN
MOVER. Felix M. Barker, OD, MS, Dane Spriggle, BS, Jon

Schoenfeld, BS, Sara C. Rojas-Mendez, OD, Hafter Family Light and Laser Institute, Pennsylvania College of Optometry , Philadelphia, PA 19141; Roger M. Birkbeck, Omnigon Corporation, Heston Hall, Suite 208, 1790 Yardley-Langhorne Road , Yardley, PA 19067.

PURPOSE: The purpose of this study was to determine the effect of sustained near point work on a video display terminal (VDT) on the dark focus of accommodation, and the potential mitigating effect of varying the screen distance during the task. METHODS: Subjects were two Optometry students with active accommodation (ages:23 and 26) who viewed a VDT at 16 in. for a period of 1 hour or while the screen was moved from 16 in. to 23 in. (rate =27in./min) on a 'REFOCUS' VDT mover (US Pat. # 5263678). Dark focus of accommodation (DFA) was measured using a HeNe laser optometer with a rotating drum located at 15 feet. Accommodative status was determined by matching the speed of the moving speckles generated with an optically generated speckle pattern. Subjects viewed the laser and the optical speckle patterns through a +8 D lens, which eliminated all stimuli to accommodation. RESULTS: Pre and post-task DFA comparison indicated inward shifting of accommodation (32 % change) a change that was virtually eliminated with continuous alteration of viewing position by use of the REFOCUS Device (<1% change). DISCUSSION: The dramatic effects of this study offer a potential for a real solution to accommodatively based eyestrain syndromes among computer workers. (Study funded by a grant from ALMAY)

Here's the abstract from the patent for the VDT mover:
(found from URL <http://patents.cnidr.org/access/search-bool.html>)

A device for slowly and smoothly displacing the display unit of a terminal such as a computer work station has a base and a platform movably supported on the base. The platform supports the display terminal and is oscillated back and forth along a path by a linear actuator disposed in the base. A shaft is mounted for rotation on a longitudinal axis and has a groove along the length of its outer surface helically inclined at an angle to the longitudinal axis. A motor rotates the shaft and a follower rides in the groove on the shaft and is connected for transmitting linear motion to the platform as the shaft rotates. The groove includes bidirectional helices joined at the ends by a circumferential groove section. The motor can be a synchronous motor with a gear arrangement providing an output which is laterally and downwardly displaced

relative to the motor, whereby the shaft is compactly located immediately adjacent the base of the device providing the device with a low profile capability.

Hey folks,

I'm a new guy on the list and I thought I'd introduce myself before I bombard you with all my questions. My name is Mike and I am a 27 year old airline pilot. I was 20/20 all my life until just a few years ago. I have never worn negative lenses, except for a short trial period of using Ortho-K lenses. I am now about -.50 D myopic, and I want to return to perfect, uncorrected vision.

I have read Brian Severson's "Vision Freedom" material, Otis Brown's "How to Avoid Nearsightedness", and Donald Rehm's "The Myopia Myth". I have read a number of articles on the subject on the net, including PhD theses for the University of Queensland in Australia. I then discovered the "sci.med.vision" newsgroup and started / participated in some discussions there. From there I was introduced to the I_See web page and this list. I read Alex's essay and a bunch of the mailing list archives.

My first question is a simple one: Has anyone on the list returned to **perfect** uncorrected vision. It seems like the "final step" to 20/20 is the hardest / slowest to achieve. With my low degree of myopia, my entire recovery consists of this "final step". While a friend of mine who is much more myopic has had dramatic improvements, my progress has been less than stellar.

Mike
Airline Transport Pilot / Flight Engineer,
Boeing 727

Dear Mike: FIRST AND MOST IMPORTANT QUESTION - Do you use aspartame marketed as NutraSweet, Equal, Spoonful and who knows what since the patent expired?

A lot of pilots sip diet drinks and put Equal in their coffee. The wood alcohol (methanol) in aspartame converts to formaldehyde and then formic acid in the retina of the eye and destroys the optic nerve. It commonly causes tunnel vision, retinal detachments, blurred vision, floaters, flashes, black spots and blindness. On our auto-responder are documents by physicians, Dr. H. J. Roberts and the late Dr. Morgan Raiford. The I-See web page has NutraSweet, poison to the eye. I will forward you a post I do for pilots which lists a bouquet of aviation magazines that have warned pilots off aspartame.

Also, because of the altitude the wood alcohol is more prone to cause aspartame problems in pilots. Aspartame is not an additive, but a drug, that changes brain chemistry, changes the dopamine level of the brain, and interacts with other drugs. It is a seizure triggering drug and is causing pilots to have grand mal seizures. On HARDCOPY a couple of weeks ago they had two pilots, one that had a grand mal seizure, Haynes Dunn, who was a pilot for Continental - and with a plane load of passengers, and also a pilot who blacked out. I just had a pilot contact me who said he couldn't make a decision on aspartame and had an accident. WE fly packets around the world to air traffic controls to warn pilots.

Dr. H. J. Roberts, world expert on aspartame, and author of many publications and books and tapes has written DEFENSE AGAINST ALZHEIMERS DISEASE and explains the memory loss and how aspartame is escalating Alzheimers. He also has tapes. Not exactly for pilots - many pilots state they get confused. You can get his publications by calling 1 800

-814-9800.

You may have read in the paper Dr. Olney's new study on aspartame and how brain tumors of the type that developed in the original studies in the rats are now escalating throughout the publication, and not just in America. The news is now worldwide on it and is coming in from many countries.

Instructions for our auto-responder are beneath my signature. I'll send you our warning flyer which quotes FLYING SAFETY, journal of the U.S. Air Force who has warned all pilots off aspartame. They say it doesn't take any more aspartame than in a piece of sugarfree gum. Dr. Roberts says thats one of the worst because its just like putting nitroglycerin under your tongue, small molecules, goes straight to the brain. The wood alcohol also causes headaches.

Watch for more news on aspartame in the media.

Regards,
Betty Martini
Founder
Mission Possible (warning the world about aspartame)

Also NOTE TO THE I-SEE NEWS GROUP. I don't know how many of you know this who use computers that affect eyesight, but when you get a pair of glasses you can ask for a film that will prevent computer damage to the eyes. Immediately over a year ago I noticed vision problems when I got on internet and got a screen, and put sea salt in packets on the computer. When I still had problems i began t use bilberry and Vitamin A &D. However, as my days became 18 and more sometimes and I became very very busy, I stopped taking supplements because I would forget. Finally I realized I couldn't read print in the paper. Somebody called me from IDT and said: There are screens and more expensive screens, the difference in using good or better sun glasses, - and anymore who stays on a computer as long as you do should without fail ask for the film to put on your glasses to prevent computer damage. So I went to the eye doctor and sure enough my right eye had gone from 20/20 to 20/100. I have to pickup my new glasses today which now have the film on them. I wish somebody had told me over a year ago, and it was just absurd to stop taking bilberry and other material that had kept my eyesight okay. Now I'll do it all. Just a warning to the wise.

Regards,
Betty

A few weeks ago, there was a discussion about blue-green algae/Cell-Tech, and someone helpfully mentioned that she used Cell-Tech for some time without experiencing any noticeable improvement, but then tried something new and almost immediately felt more energetic. She kindly provided the 800 number, and I know I saved it - but darned if I can find it anywhere. Would that kind person (or any other kind soul who may have saved this information) PLEASE be so kind as to EMail it to me? (I say "to me" to avoid further imposing on list members who are either not interested or who saved it the first time.) (This is NOT Cell-Tech: it is the company someone said she, herself, considered better than Cell-Tech.)

On the subject of eyes, an uncle by marriage recently lost most of his vision and was diagnosed as having a blood clot in his eye. (He had had a complete eye exam less than a month ago, and was told that his eyes were in excellent shape with no problems.) He is now being treated with cortisone, and his vision is slowly returning. Does anyone know what causes a blood clot in the eye, and HOW TO AVOID THIS PROBLEM?

Thank you VERY much.

Virginia

I_seers,

I was reading Aldous Huxleys book The Art of Seeing. When i stumbled upon one of the vision games. Here it is:

Take both of your index fingers and place them two feet from your face and about 18 inches apart. Look at the either finger. The finger that you look at should be more ditinct then the opposite one. For example when looking at the right finger, it should be seen clearer then the left. You can change the distance of your fingers if you like. Aldous says that this proves the phenomenon of central fixation.

When i look at a finger, the opposite one is more distinct, does this mean my central fixation is out of whack? keep in mind that i do this without my glasses. I am a high myope also.

I do the central fixation game that Bates mentions in his book. It has to do with looking at a letter, for example the top of the letter and seeing it better then the bottom of the letter. Then doing the opposite looking at the bottom and seeing the top worse. Then doing the same for the sides of the letter.

Are there anymore vision games one can do for improving central fixation?

Does anyone notice the same results ?

I would appreciate any comments or suggestion.

Have fun and keep smiling,

-Peter

Barry

I'm afraid I don't know. I had assumed that the company was called Vision Care, but I may be wrong. It's some kind of miniature eye chart that you view through an eye piece. Then you move the eye chart further away on a slider and read it again. I know that's a bit vague, but I haven't actually seen one of these, I've just had it described to me. I think it just sounds like a pure 'focussing at different distances' exercise, which is why it puzzles me when people say it is having such immediate and dramatic results. If it really works like this, firstly you wouldn't need a machine in order to do the exercise and secondly, why are we all trying other things that take months or years when something so immediate is available?

I guess it goes along the 'too good to be true' lines, except that the person who sent me this message and some of those who have tried it are ex-colleagues of mine, so I trust that when they say their eyes have improved, they have.

Caroline

Hi Caroline-

I guess I'm picking this thread up in the middle. What is the Vision Care product, and who sells it to the best of your knowledge.

Hi all! This is your moderator speaking, Alex Eulenberg. I'd like to apologize for the delays in approving letters over the past week or so. I have recently started a new full-time job (as telephone consultant) and as a result starting paying less attention to I SEE. In general, I have been less active on the list, as I'm sure many of you have noticed.

I have also not been archiving the list (on the web site) since March of this year. Most of my justification for moderating the list was that I wanted to slow the list down, thus making the monthly archives smaller (my disk space is finite). Now I'm beginning to think that not everyone would want their comments preserved in perpetuity. So I'm going to make I SEE unmoderated again, saving me some keystrokes, and speeding up delivery of messages.

I'd also like to hear comments on how the list is doing. It's almost two years old now (Founded January 1995).

It's likely I won't have access to a free majordomo list for much longer. Perhaps March of 1997 will be the end of it, at least with me as moderator/administrator. If anyone has the ability or inclination to pick up the torch, let me know.

Welcome. -0.50 would be good enough for me :-)

[SNIP]

> My first question is a simple one: Has anyone on the list returned to
> *perfect* uncorrected vision.

Since I've been on the list (about a year), there have been two reports of going from -8.0ish and -10.0ish to 20/20, but they haven't been on the list for a while.

> It seems like the "final step" to 20/20 is the

I've heard second hand reports (always more difficult to believe - probably rightly so) of people who come from moderate/high myopia finding it easier to go the whole way, than those who start off with mild myopia. Once they've found out what they've been doing wrong,

then its more obvious to them.

Peter

Hi. Mike(and everyone else)

i'm new to the list too. I'm a 20 year old college student with about 40 flight hours logged. My vision is about 20/30 to 20/50, depending on how stressed out i am. I would love to be an airline pilot in a few years but i need to do some serious vision correction first... does anyone have any input about those programs such as Michael Kaplan's course with the audio cassettes and that sort of thing...i'm new at this and any advice would be tremendously appreciated.....

thanks
Jeff

Greetings to you all! I'm also new to the list. As someone above said, -.50 would be fab with me! I'm currently in the -8.00, -9.00 range & finally found a nearby doctor who believes in this stuff. I'm researching like crazy and would do anything even for a -2.00! The doctor I'm seeing has prescribed +1.00 lenses to wear reading over my contacts. That's about as far as I've gotten. I have heard of pilots correcting vision before, but that's about it. For me, this is a last chance before I go for PRK. I hope it works!!!!

Has anyone heard of an accomatrack?

: -)

I don't know anything about "Vision Care", but I have a little vision
tester that's like what you described that I wrote about to this list

in August (edited to put in correct prices):

>>At 02:19 PM 8/19/96 -0400, Marco Terry wrote:

>> >Anyone knows where can I get a cheap eyechart (I need to start baseline
>> >measurements)

>>

>>You can buy an eye chart from Edmund Scientific (<http://www.edsci.com>) for
>>\$7.95 (A52,517). I bought one of theirs long ago.

>>You might also be interested in their "Self-Screening Vision Tester"

>>which is a cute little device with a (cheap plastic) plus lens

>>and a very tiny Snellen chart that you slide back and forth. You

>>find the distance at which you can see the 20/20 line and you

>>read your diopters of nearsightedness right off the scale. You can

>>also measure the near point too (and need for plus lenses).

>>I've enjoyed playing with it, but I'd really rather have a more

>>repeatable measurement of refractive error. It's \$14.95 (A38,624).

You can reach Edmund at 609-573-6250 M-F 8a-8p ET, Sat 9a-4p ET
(\$5.95 shipping up to \$25 order)

I had spent a lot of time playing with this little tester but I
don't think it magically fixed my vision. The best thing I found
for fixing vision was practicing focussing far and practicing
clear flashes, described in my 10/29/96 note to this list.

I've seen the identical eye chart (not the little vision tester)
at small medical supply shops too.

Also in reply to the same question came this from Beyond 20/20 Vision:

>From: Beyond_20/20@Sunshine.net (Beyond 20/20 Vision)

>

>we have a laminated chart called an Eye -C chart which is logrithmically
>designed and a greater training chart. has exercise instructions on the back
> and a conversion chart into percentages Cost -\$10 includes shipping and
>handling

At 09:37 PM 11/11/96 -0800, Dawn Isaacson <charade@worldnet.att.net> wrote:
>Has anyone heard of an accomatrack?

The accommotrac was invented by Joseph Trachtman in 1986. See US patent number 4,660,945 "Methods and apparatus for accommodation training":
<http://patents.cnidr.org/cgi-bin/linker3?/pto7/NEW/INDEX+4660945+F>

(It shines an infrared light into your eye and measures the reflections, and makes different beeping noises according to how you're focussing.)

"Methods and apparatus for performing accommodation training under clinical conditions are provided in accordance with the teachings of the present invention. An infrared optometer is employed to measure a patient's accommodation and outputs therefrom are employed to generate tone information and viewable patient information indicative of the state of focus in a rapid manner. A patient is trained at an empirical rate determined by the viewable information until a predetermined proficiency in the voluntary control of accommodation is achieved. Thereafter, stimuli to accommodation, the accommodation convergence reflex and blur cue information are selectively introduced to generalize the voluntary control of accommodation achieved to a conventional environment so that the same may serve to reduce various visual acuity problems in a patient being trained."

Someone promoting Accommotrac in their practice:
<http://www.pathwaysdc.com/vision.html>

Not accommotrac, but related inventions:

US Patent number 5,374,193 also by Trachtman (filed 1990):

<http://patents.cnidr.org/cgi-bin/linker3?/pto7/NEW/INDEX+5374193+F>

"Methods and apparatus for use in alpha training, EMG training and dichotic learning"

This measures your brainwaves as well as eye parameters to help train you on strabismus, nystagmus and eccentric fixation.

US Patent number 4,997,269 is for

"Scheiner-principle pocket optometer for self evaluation and bio-feedback accommodation training" See on the web:

<http://patents.cnidr.org/cgi-bin/linker3?/pto7/NEW/INDEX+4997269+F>

US Patent number 4,778,268 is for

"Visual accommodation trainer-tester"

"The invention is an apparatus for training of the human visual accommodation system. Specifically, the apparatus is useful for training a person to volitionally control his focus to his far point (normally infinity) from a position of myopia due to functional causes. The functional causes could be due, for example, to a behavioral accommodative spasm or the effects of an empty field. The device may also be used to measure accommodation, the accommodation resting position and the near and far points of vision. The device comprises a number of optical elements arranged on a single optical axis (74). Several of the elements are arranged in order on a movable stage (20) in fixed relationship to each other: a light source (30), a lens (32), a target (36), an aperture (42), (48) or (52) and second lens (58). On base (18) and in fixed relationship to each other are eyepiece (70) and third lens (64). Stage (20) generates an image (72) of target (36) and the stage is movable with respect to base (18) by means of knob (22). The device is utilized for the various training and test functions by following a series of procedural steps, and interchanging the apertures as necessary for the selected procedure. "

In most cases of back to "normal" vision that I've heard of, the person still has some trouble seeing at night. I also can see 20/20 during the day with good sunlight outdoors (I started 1 year ago at about -4 D) but my indoor and night vision has a ways to go. It's slow but continuous improvement (with about 1 in 10 days seeming hopeless, though.)

One suggestion for helping with the "final step" is to wear plus lenses. Use, say, +1 D outdoors and +2 D when reading or working on the computer. Use stronger lenses if you can still work with them. Hang an eye chart near where you work and look at it periodically

and read the smallest letters you can -- with your plus lenses still on. If you can, spend time every day with an eye chart OUTDOORS or in as bright sunlight as you can manage. It doesn't matter for this purpose how far the eye chart is, so long as you can read 30 to 70% of the way through it.

(You can get plus lenses ("reading glasses") at drug stores for \$10-15.)

If you get good at bright light vision, then start practicing with dimmer light.

After a lot of reading, the most informative literature I have found is this book:

THE MYOPIA MYTH; The Truth About Nearsightedness and How to Prevent it.
By Donald S. Rehm,
International Myopia Prevention Association
RD 5, Box 171
Ligonier, PA 15658

(\$15 including S&H)

Best 15 bucks I ever spent!

Also, check out these PhD theses on vision research on the web:

<http://www.vthrc.uq.edu.au/vthrc/Theses/Theses.html>

(Not all the theses are on vision, but you can look around and find some really interesting stuff.)

Good luck,
Mike

PS, if all else fails, you can still be a pilot as long as you are "corrected" to 20/20. However, try to keep your medical clean (no requirement for lenses). (I have had the best luck with plus lens therapy.)

Dear Virginia: You are right that some vitamins contain aspartame and the major culprit is Twin Labs. When Return To Eden, an organic market and health food store, insisted on knowing how many of their products contained aspartame Twin Labs admitted to 30. Twin Labs said if we could show proof that aspartame was a poison they would take it out. They were sent over 100 sheets of technical information, articles, scientific studies, case histories of those who had gone blind on aspartame, etc., etc. They wrote back and said they were not going to take it out, period.

So we Boycott Twin Labs and don't trust anything they have. I have a friend who is allergic to formaldehyde and was using Twin Labs, and she couldn't understand why she was so sick.

If you happened to see HardCopy a couple of weeks ago you may remember the little girl they thought was dead. She was revived at the hospital and the culprit turned out to be aspartame in her vitamins.

And now the Director of the National Yogurt Association has petitioned the FDA to not have to label it as having aspartame in it. And its being put in things you might not think have it, like Fresca and Winterfresh gum. And in June they approved it in everything in the grocery store.

So you have to be extra careful. A lot of the media now are exposing it, and I'm constantly asked to write magazine articles, etc.

Regards,,
Betty

P.S. The only way to be sure is to ask the people who make the line of

vitamins if they contain aspartame.

To get more information on aspartame, email betty@pd.org as follows:

Betty says that after using the computer for a while, she has become nearsighted in her right eye (20/100). As a result, she went to LensCrafters and got diagnosed with astigmatism and was prescribed bifocals with a special film that she claims lets her see better in the night.

I seriously doubt that the "film" has improved her night vision. How can any coating on a lens (albeit an "invisible" one) improve night vision? Far more likely, it is the "minus" or "myopic-astigmatic" part of Betty's prescription that is doing the job.

The fact is, the effects of myopia are aggravated in low-light situations. This is called "night myopia." Bright light often brings vision of low myopes up to 20/20, as our pilots on this list have observed. This is due at least in part to the fact that the pupil gets smaller in response to light (there may also be some other considerations involving the lens). The smaller the aperture, the greater the focal range. This is how pinhole glasses work.

If you want to decrease radiation from your computer screen, you should get a anti-radiation/glare screen (not all anti-glare screens are anti-radiation -- read the fine print!). This can be had for \$30-\$50 -- less than a pair of prescription glasses, and then anyone who uses your computer can benefit. This screen will cut out radiation to all of your body, not just your eyes.

I'd also like to add at this point that I believe Betty would be able to get herself back to 20/20 by using spherical (not astigmatic!) plus lenses for close work. I'm curious what her prescription is now, though.

Betty?

Hi Alex: Thank you for telling me about the anti-radiation screen. I just picked up the only one they had, and didn't know what to ask for. But I'll definitely change it. And I'll print out your note and give it to the optician and ask for a copy of the prescription. The only thing he mentioned was the 20/100 in my right eye. I'm glad to hear you think I can regain my vision.

Regards,
Betty

Another option is to use an LCD display (such as on a laptop.) These displays are supposedly radiation free (not sure if this is possible, wouldn't the display be pitch black if it was truly radiation free?) and also flicker free! I've noticed that laptop screens are definately easier on my eyes. Of course the laptop display may be too small for extended viewing comfort.

A company called SCEPTRE has a new product which is a 15" LCD display made for the desktop computer. In addition to being radiation and flicker free, it is much less bulky and much lighter than traditional

tube displays. You can get the new display for about \$3000 and it only does 800x600 ... but you'll have to decide if your eyes are worth it..

Sceptre is supposedly also going to have a 17" version out soon. I may get one, when they come out ...

I've got a brochure on the monitor.. to get one, call

Link Computer, Inc (a Sceptre distributor)
16800 East Gale Avenue
City of Industry, CA 91745
Contact: Terry (800) 800-8546 x2105

This is not a sales pitch!

You can get a referral to a vision therapist in your area by calling the Optometric Extension Program Foundation in Santa Ana, CA at 714-250-8070.

I thought the Bates stuff was too weird but..... I think it was the year before last that I was given the book *_Healing and the Mind_*, by Bill Moyers. A friend who is a massage therapist introduced me to Jin Shin Jytsu, a form of accutouch. I also went to some Kundalini yoga classes at the gym.

Bates palming and swinging look very much like exercises used to open up energy blocks. Another friend lent me this video on Qi Gung- kind of like Tai Chi. The guy in it goes over some movements to open up your chakra points, one exercise looks exactly like swinging. Much of the world recognizes that there is a human energy field. I have read abstracts on controlled studies on accupuncture showing a measurable effect. I think that implies that there is a human energy field. I'm presently reading David Eisenberg, M.D.'s book *_Encounters with Qi_*. You've probably seen things on TV about major surgeries being done with only accupuncture as anesthesia. It is more and more clear to me that there is a human energy field and it can be manipulated by needles, accupressure, accutouch and probably crystals and prayer (see books by Larry Dossey, M.D.-)Try and keep an open mind on this.

Just for one week, do 100 long swings morning and evening and see if you don't notice an improvement.

Dolores Kreiger's *_The Therapeutic Touch_* or Tom Harper's *_The Uncommon Touch_* give nice outlines on some of the research on energy medicine. I'm inclined to think European based cultures lost their best practitioners of energy medicine, their chi gung masters, by burning them at the stake as witches. There's a fascinating book on the history of the witch burnings in Europe- I think it is called *_Witch Craze_* By an Anne L....., I can't find the book, I must have lent it out or stuck it somewhere.

After reading Julie's recommendation, I bought this book and read it.

I've read perhaps 20 vision books in the past year, and I thought this was the best. It's not perfect, but it's a great combination of specific advice, including how to integrate the advice into your busy lifestyle, as well as an appendix with more technical details (some, anyway) such as what prescriptions to get, specifications for bifocals, and how your acuity can increase, with or without a change in measured refractive error. This latter point is almost always ignored -- "how can you get better acuity without changing your prescription for 'best' vision?" It happens, that's a fact, but why? How?

I also found in it the first plausible explanation I'd seen for how one

can prevent cataracts in presbyopes (not my problem yet!)

Many of the exercises I thought I had invented (though based upon the giants' shoulders I stood on) so I can say that they worked for me.

The authors actively solicit feedback from the book's readers. They say they've done these techniques on 10,000 people with success.

Like Julie, I've already been giving away copies... (\$9 at a bookstore near me, \$10 at barnes and noble) Thanks for the inspiration, Julie!

Amazon books has this for \$9 (plus 95c/book plus \$3/order shipping) at <http://www.amazon.com/exec/obidos/ats-query/7205-3614232-551002>

When light crosses between two materials with differing indexes of refraction (such as air into glass, or glass back into air), a certain amount of the light is reflected, and the rest goes through.

The smaller the difference between the two indexes of refraction, the less light is reflected, and the more light goes through.

So, if air is 1.0 and glass is (say) 1.3, you might put in 10 layers of material between the air and the glass. The indexes of refraction then might go 1.0 (air) 1.03 1.06 1.09 ... 1.27 1.30 (glass). The boundary to each layer lets most of the light through. All told, even though there are so many surfaces to reflect, the total reflection is ONE TENTH what it would be if you had simply air and glass. That is, more light reaches your eyes so you can see better at night.

This is what you get when you buy "anti-reflective coating" on glass. They have to send it out (at least Lenscrafters does) because it is time consuming and requires special liquids to dip the glass into, and you can only do it AFTER the lens is ground to the right prescription.

They dip it many times, letting it dry each time. This is why they charge \$60 or so for it.

If you see someone wearing a pair of glasses with one lens with anti-reflective (AR) coating and the other lens without it, you see a DRAMATIC difference between the two eyes. Through the AR coating lens you can easily see the eye. In the other lens, you see reflections of everything as usual. The AR coating can thus improve the cosmetic appearance of glasses as well.

All the above is true, but it's more important for high-index glass. For $N=1.6$ glass, with light coming straight through, 95% of the light goes through and 5% is reflected. With 10 layers of AR coating, 99.4% of the light goes through. If you want to work this out for yourself, the equation for amount of reflected light is $R = (N'-N)^2 / (N'+N)^2$ where N' is the glass index of refraction (say, 1.6) and N is air's (1.0) and 2 means squared. For ordinary crown glass, $N=1.52$, $R=4.3\%$. For Lanthan Glass, $N=1.89$, $R=9.5\%$ (but I've also seen 17% from a Usenet post by Bram Vingerling who does this for a living.)

Reference: Modern Optical Engineering, 2nd Ed, Warren J. Smith, p.187

In any case, Alex is certainly right that "correcting" the myopia plays the biggest part in improving night vision.

I also don't know for sure that this is the "film" that Betty got, but it does seem to fit the facts we've seen so far, except the extra cost.

What's PRK?

I didn't get in on the discussion about the "accomatrak" here.

(Yes, Alex, it's spelled "Accomotrak", I hear ya.)

>From reading the Natural Vision FAQ at <http://www.cia.com.au/vic/faq.html>

I understand it's some kind of biofeedback device?

How much is it and does it work?

If everyone is sick of talking about this, some kind person could always send me the info privately. :-)

I'm going to try the simple every day eye exercises first before I rush out and start spending a lot of money on all kinds of eye improvement gadgets. I'm looking at this as a life style change.

>As for exercises, etc, there's tons of books. I like the one "Natural
>Vision Improvement" by Janet Goodrich. Although it's kind of hokey, it has
.some of the best advise I've seen. She works some of (my favorite) Asian
>"Yoga" eye massages into the routine.

Thanks for recommending a good book for eye exercises. I'm finding that a lot of vision improvement books are heavy on theory and then only give a few eye exercises to do. I did find a book at the library that has lots of exercises. It's called "Visionetics--The Holistic Way To Better Eyesight, by Lisette Scholl, copyright 1978, ISBN: 0-385-13279-4. She has yoga stuff in there too. It must be out of print, because none of the local bookstores

could order it. I am currently trying to get the book through a hard-to-find book source on the Internet. In the meantime, I photocopied a lot of the book so I could practice the exercises.

The eye massages feel wonderful! Gentle pounding around the bony perimeter of the eyes with your middle fingers is one I like. Also massaging certain acupressure points like the upper inside part of the bony ridge above our eyes, and the ones by our nose--to find them, place your middle fingers beside your nostrils to get your index fingers the right distance from your nose, then rub in circular motions with the index fingers. Use your thumbs to support your chin. I don't have any problem finding these acupressure points, because they are very sore.

Drawing imaginary figure eights in the air with my nose while "sunning" feels great too.

What is your favorite eye exercise everyone?

Kip wrote:

>Could you describe this "top of my left eye" part better? Do you mean
>you look at a point, and you see things ABOVE that point clearly though
>the point itself is not so clear? William Bates' books talk a lot about
>that, saying you need to work on your 'Central Fixation'.

What I am actually looking at is what I see best, so I don't believe this would be called a central fixation problem? For example, when I look at the letter "C" on the eyechart the letter is fuzzy if I am looking straight ahead at it. (Left eye is patched.) If, while still looking directly at the letter "C", I tilt my head so that my right eye rolls up and to my left the letter "C" is clear. Weird, huh?

Virginia wrote:

>Does anyone know how Lutein helps the eyes?

Hi Virginia,

Evidently, lutein is a carotenoid (as is beta carotene).

It's found in dark green, leafy vegetables such as spinach and also broccoli.

Lutein is concentrated in the macula, the central area of the retina of the eye.

It may help prevent age-related macular degeneration, a very common cause of vision problems in old age.

Goto

<http://ultra.infoseek.com/>

and search on "lutein"

for more details

About TwinLabs putting aspartame in their products...could someone provide some kind of proof or documentation on this? I'm a little leary of vague damaging rumors like this. I happen to us TwinLabs products and it says right on the bottle "no artificial sweeteners".

Mari,

i've never read anything about it, but my personal experience is that emotions have an immense effect on vision. my vision is normally in the 20/40 to 20/50 myopic range, but if i'm upset or stressed out for a few days in a row my vision becomes dramatically worse. since i've been doing eye exercises and wearing +3.25 lenses a few hours a day, it seems that stress doesn't affect my vision nearly as much. i guess when the muscles of the eye are strengthened, they aren't as susceptible to stress related problems. i'd be interested in reading more about this subject as well, Mari....

hi everyone,

i never really liked palming and found it difficult to relax while holding my hands over my eyes... the other day i found the "Happy Eye Pillow" at one of those nature stores...its a little rayon pillow with flax seeds inside. i've been using that instead of palming and getting much better results...with the pillow over my eyes i can see almost no light at all even with my eyes open.. they cost 10 bucks..but they're well worth it...

call 1800 486 2896 for more info....

Eye pillows are also very quick and easy to make, and make a thoughtful gift. You can find flax seed at the health food store; if in doubt, ask a vegetarian where to get them. (We use them as egg substitutes, among other things.) And these are VERY soothing for the eyes.

I hope you'll find this helpful:

EYE PILLOWS
copyright (c) 1994 Virginia B. Sauer

Soft, soothing eye pillows advertised for \$ 16.00 - 20.00 (plus tax and shipping) can easily and inexpensively be made at home.

These are very soft, soothing pouches that you place over your eyes when you lie down to rest or sleep. The bag will slide off during the night, and most people find that they wake up refreshed. Many claim that this also relieves headache/sinus problems, since the little pillows massage your eyes while you sleep.

=====
MATERIALS NEEDED
copyright (c) 1994 Virginia B. Sauer
=====

20 1/2 x 5 1/2 inches sand-washed rayon (a very soft, soothing fabric that does not allow moisture to sleep through) or satin in color/style of your choice

Needle and thread (in color matching that of fabric)

4 cups flax seed (preferably organically grown)

1 cup lavender flowers (optional)

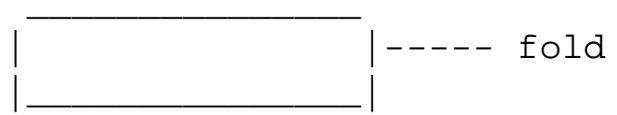

- . This is ideal for inducing sleep and reducing headaches/eyestrain.
. If preferred, an additional cup of flax seed can be substituted.

2 - 3 feet 1/2-inch grosgrain ribbon in color that complements that of fabric (lovely, but optional; only necessary if making variation with ribbon ties).

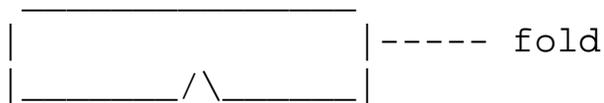

=====
PROCEDURE
copyright (c) 1994 Virginia B. Sauer
=====

-- Iron fabric. Fold each short (5 1/2-inch) side under about 1/4 inch. Iron to hold in place.

-- Fold fabric in half lengthwise, right sides together.

- If desired, cut inverted "V" from center of one edge of the long side, creating a mask without eyes.
 - . Although in no way mandatory, this will make it more "professional-looking" for gifts, and enable the pillow to fit comfortably over the nose.
 - . Make cut high enough to be noticeable even after seam allowance is sewn (e. g., if using 1/4-inch seam allowance, make V-shape extend 1/4-inch longer than necessary).

- Stitch together long sides, making 9 1/2 x 5 inch pouch.
- Invert pouch, so that right sides are outside.
- Mix flax seed with lavender flowers to evenly distribute.
- Fill pouch 2/3 - 3/4 full with the flax seeds and/or lavender flowers.
- Stitch open end closed, creating pouch.
- When giving as a gift, attach a tag with the following label information.

LABEL

copyright (c) 1994 Virginia B. Sauer

EYE PILLOW

Pillows for your eyes.

Eye pillows comfort and massage your eyes when you are resting or napping. Filled with soothing flax seed and lavender, they are designed to put gentle pressure on the accupressure parts of your face to block out light and reduce eyestrain.

They can be used either at room temperature, or placed in the refrigerator or freezer to create a cooling pack for your eyes or neck.

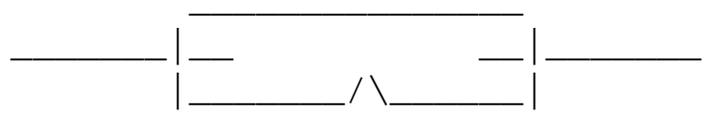

Although many people claim to use these throughout the day to relieve eyestrain, others find that they induce sleep. Accordingly, experiment with it at a time when a nap would not present a problem (e. g., not ten minutes before making a presentation).

=====
VARIATION(S)
copyright (c) 1994 Virginia B. Sauer
=====

EYE PILLOW FOR TRAVEL / USING IN UPRIGHT POSITION
Copyright (c) 1994 Virginia B. Sauer

If you anticipate using these on airplanes (or at other times when in upright or semi-upright position), add ribbon ties to enable pillow to remain in place.

- Either substitute two 10 1/4 x 5 1/2-inch pieces of fabric, or cut cut fabric in half (creating two 10 1/4 x 5 1/2-inch pieces).
- Cut grosgrain ribbon in half.
- Slip ribbon between short sides of fabric (so that approximately 1 inch is hidden).

- Proceed as above.
- When finished, cut inverted V-shape from each exposed end of grosgrain ribbon.

-- Amend label instructions to include tying ribbon into bow behind head to hold pillow in place when using in upright or semi-upright position.

EYE PILLOWS USING BUCKWHEAT HULLS

Copyright (c) 1994 Virginia B. Sauer

Many people recommend substituting buckwheat hulls for the flax seed. However, I, myself, have never tried this.

EYE PILLOWS USING MUSTARD SEEDS

Copyright (c) 1994 Virginia B. Sauer

-- Eye pillows can also be made with mustard seeds instead of (or along with) flax seed.

-- These are especially nice for someone under great stress, accompanied by an appropriate label.

- . One one side, print a description of the eye pillow, and the fact that it contains mustard seed.
- . On the other side, print the following Biblical quote:

"And if you have faith as a grain of mustard seed,
You will say to this mountain, 'Move, mountain',
And it will move ...
For nothing shall be impossible unto you."

Matthew 17:20

EYE PILLOWS TO INDUCE SLEEP

Copyright (c) 1994 Virginia B. Sauer

If you want the pillows to induce sleep, mix the flax seed

with lavender flowers, hops, camomile, and/or catnip (although the latter should be used only if you do not have a cat).

Copyright (c) 1994 Virginia B. Sauer

I just got this at the local Barnes and Noble. I wouldn't bother to order it yourself from the publisher, any B.Dalton etc store might have it and should certainly be able to order it. It's only \$10

You probably don't want to "get" one, unless you have a spare \$20,000.

Many vision therapy practitioners use the accommotrac as a key tool in their therapy.

I used to accommotrac for about 10 sessions or so a few months ago. I gained back about 1.5D (from -6 to -4.5) of vision during that time, but I honestly think the improvement was more due to the other more holistic techniques I was using during that time (such as palming, massage, blinking etc.)

To find an accommotrac near you, I suggest you look up vision therapy in the yellow pages, and make some phone calls. Thats what I did, and if you are in a metropolitan area, you are bound to find one or two practitioners that have one.

I haven't forgotten the request for more information.....

To: Richards, Caroline

Sounds like the same thing we are talking about..... exercise the eye muscle by focusing far and near..... like a viewmaster.....slides are lite from behind.....

The salesman will be coming to my house to change a slide on it. I wanted a slide that is just stripes on it so that I could focus on lines, it's good for astigmatism. I will ask him about how to get one in Australia. Will let you know next week.

Bye,

Mei

Mei

I've had quite a bit of response from people regarding your vision care stuff. Some people are asking who the supplier is and how they can order it. Do you have the information or is it only available in Singapore?

Thanks

Caroline

Regarding radiation and computer screens, I thought I'd tell you what I was told myself recently. I'm not sure if it is true or not, but the guy who told me lost a sale through his advice so I tend to trust him...

I'm pregnant and was trying to enquire about lead aprons since I do so much computer work and a homeopathic doctor had recommended the apron for safety. Unable to find a normal retail supplier, I called an X-ray equipment company and asked to speak to the sales department.

The man I spoke to said that they had lead aprons of all qualities and that he could certainly sell me a single one if I wanted, but that he thought it was unnecessary. He quoted some government (Australian) health department (I forget the exact name) which had measured the radiation output of 'modern' screens, and found it to be negligible (and even more so for those of us who try to sit further back for the sake of our eyes!).

I'd still err on the side of caution, but I thought it was encouraging news.

Sorry, Caroline...

I guess I didn't answer the question in the first place! I don't think it's the type of machine you'd want to order, or even be able to afford to order. (Well, maybe you could....) First off, you need two people for it: the technician centers the machine on your eye & makes adjustments as you work on it. You need to time how long you do it each sitting, or your eye will get fatigued. As your eye relaxes, you receive a feedback noise that lets you know how you're doing.

On the other hand, there will be some computer programs coming out that, while they're not exactly the same thing, can work your eye in the same manner. As soon as I find some info, I'll send it to you!

One thing I can tell you...After months of doing eye exercises & massages only, the machine was the first thing to have some affect! I can actually see (and feel) some improvement! After the first time I used it, my eyes felt wide open & relaxed! And now I realize that the times I can see clearly, my eyes feel the same as if I were using the machine!

As for expense, here in the NYC area it's ridiculous, but someone assured me the other day that certain insurance co's will cover a part of the expense. Now I'm out searching for the right co!

: -)

1st a comment about unknown vision therapists. I called one who was listed in the back of Jacob Liberman's book Take Off Your Glasses and See and was local to me. I talked to him on the phone 1st about what I was doing. He said yes, yes. He did that. I went in for an appointment. He immediately put me through a standard stressful eye exam and basically told me I was too old and my eyes too far gone to change. We ended up having words and agreed that there was no way we could work together. Since then (Mar 95) I have reduced my prescription more than half. When I get to 20/20, I am considering going back to him to show off. And I also don't want to waste the time, energy, or money. So, the point is be cautious when choosing someone to work with - trust your instincts.

Energy systems around and in the body. Carolyn Myss' Energy Anatomy is very good. The tape series especially is well done.

Cheryl

Hey, has anyone read anything on the emotional nature of poor vision? It is mentioned in the Natural Vision FAQ, I would like to read more about this. Any books you can recommend on the topic?

Hey Alex, I think your perfectionism might be stressing out your eye muscles.
Just pickin' on ya a little bit. >:->

Back to Jeff...the Natural Vision FAQ (<http://www.cia.com.au/vic/faq.html>)
is actually talking about how there could be emotional issues connected to
poor vision. For example, it mentions:

"Myopia is a contraction and withdrawal from the world. Myopia is about not
trusting what one sees, and about seeing the world through a fear filter.
Myopia often indicates a lack of security in ones self and in general trying
too hard to achieve and to see. Myopia is also about being more critical,
analytical, judgmental and having excessive attention to detail...Children
that are abused tend to develop high myopia."

Interesting, huh? Anybody out there have more info on this????
~Mari

If you have web access, you should definitely get to know [amazon.com](http://www.amazon.com) where you can look such things up yourself. Based only upon "Energy Anatomy" and "Myss" I found this right away on <http://www.amazon.com>

Energy Anatomy : The Science of
Personal Power, Spirituality, and Health

by Caroline Myss

Bk&6 Csts Edition

Audio Cassette

List: \$59.95 -- Amazon.com Price: \$53.96 --

You Save: \$5.99(10%)

Published by Sounds True

Publication date: October 1996

ISBN: 1564553795

Incidentally, I gave a reference to Improve your Vision without Glasses or Contact Lenses, by Beresford, Muris, Allen, Young on amazon.com. However, the link I gave apparently was a temporary one. I don't yet know how to give links to a particular amazon.com book page. To find this book, go to <http://www.amazon.com/> , then click SEARCH, then enter BERESFORD as author and IMPROVE YOUR VISION as title, and click SEARCH NOW. You'll get to the book's page right away. (Thanks again to Julie for pointing out this book.)

I haven't used pinhole glasses as therapy, no, but I have seen a number of references to them. Some vision professionals are very proud that pinhole glasses cannot be sold in their states. It took some work to get them banned.

I've seen them used even by researchers writing in vision research journals. The idea is that when you look through a pinhole, your eye can be focussed anywhere (accommodated near or far) and you still see a clear image. So, your ciliary moves to its tonic of accommodation (TA) position (dark focus) where it's most relaxed. (I know many people think that it's most relaxed when you see far, but that's another discussion.)

Normally, there is a connection or "loop" between your vergence (two eyes pointing to a nearby object or pointed more parallel for a far object) and your accommodation. However, when wearing pinhole glasses, this "loop" is open (the loop being the two-way connection between vergence and accommodation, each one reinforcing the other).

I forget what they're studying in this case, other than how vergence works when not affected by accommodation. They also make the vergence "open loop" by disconnecting any common field of view

between the two eyes (much as Kaplan's two-eyed patch does).

Here's a plausible (to me) explanation for how pinhole glasses could help improve myopia (similar idea could apply to hyperopia or presbyopia):

Your eyes need good contrast (edges) to focus correctly. (If you look at a blurry picture your focus naturally drifts toward your TA). If you're myopic, you see in a blur. This blur reinforces itself since you have no good contrast (no clear edges) to use to get your focus right. If only you had some help to make the edges just sharp enough that you could use your natural focus control to bring the edges the rest of the way into clear focus, you'd be all set. Once it's in clear focus, you could perhaps reduce the "help" and keep in focus (since the edge is now clear enough to reinforce your focus on it.)

There are a number of ways to get this "help":

- bright light naturally increases the contrast
- Bright light also shrinks your pupil size which increases your depth of field (just like f-stop on a camera)
- squinting
- wearing pinhole glasses with the right size holes for the brightness level around you.
- bring the subject (eye chart or whatever) near you, then you can push it back gradually once it's in clear focus.
- blink your eyes, so a layer of tears forms over the cornea, which effectively polishes the surface.
- look through an insect screen at just the right distance so your eye focusses on the screen rather than at your TA, thereby (perhaps) making distant objects more clear.

You use "just enough help" so you get to practice going the rest of the way into clear focus, and presumably learn the muscle skills just as basketball practice helps you shoot more hoops. As you improve, you would need lower light levels or larger pinholes.

Some pinhole glasses references on the web:

<http://www.livelinks.com/sumeria/health/raids.html> (about FDA raid on Natural Vision International (NVI), confiscating pinhole glasses)

<http://www.ftc.gov/bcp/adcon/adconpro.htm> (about fraudulent advertising, includes: "I guess all of you remember pinhole glasses. They were the glasses that had the little holes in the lens and they were supposed to increase your energy level and your cognitive abilities. If you have a question about these glasses, I encourage you to call the FDA Center for Devices and Radiological Health.")

<http://www.naturesway.ie/natnews/mayjun96/eyesight.html> (UK seller)

<http://www.greenmoney.com/bensalem/cruelty.htm> (sells at \$17, Pennsylvania)

Executive summary:

Stimulating focusing through occasional exposure to clarity is
beneficial. The cold turkey approach may become unproductive after some
point. Basic agreement with quoted statement plus introduction of some
caveats.

Skip rest if time is scarce

You are adding the next piece of the 20/40 vs cold turkey discussion

that we have had for well over a year. Funnily, we haven't been able to reach a concensus. Among long-term players, Alex is taking the cold turkey side, while I am leaning more to the 20/40, which I gather is also your stance. My main argument is similar, if not the same, as yours -- that from a particular lever of blur the brain gives up interpreting it, with the accommodative mechanism assuming the resting (TA) state. Therefore, one needs some "clear" prodding, in order to make progress. I find this plausible, being constantly in a blur one may forget how clear the world should look like. Compare children with less visual memory and experience who don't realize that they are myopic.

However, major new discoveries have dented this hypothesis. As I posted to sci.med.vision about a week ago, lengthening of the posterior chamber is locally controlled (by the retina - part of the brain) as evidenced by elongation in response to hyperopic defocus with the central ocular nerve sectioned. Lengthening occurs even with the ciliary sectioned, eliminating or at least significantly reducing the influence of accomodative effort in myopiagenesis. We are, of course, more interested in the opposite process -- response to myopic defocus. Shortening of the eyeball can occur thru the same mechanism, and in fact faster, triggered by myopic defocus. Just one recent source is "Retinal control of eye growth and refractive error in the chick." at http://www.vthrc.uq.edu.au/vthrc/Theses/1991_Christine_Wildsoet.html . Chick eyes responded quickly to a +10D lens, reducing axial length. A positive 10D in most cases qualifies as cold turkey. Also, among humans, consider Linda, who claims she went cold turkey from day one at approx -9D. Reportedly, she's done great, although she is on the list, silently. The other often quoted example is Antonia Orfield who used (successfully) the 20/40 approach.

See, it doesn't appear easy to draw the line. Personally, I think periodic remembering what clear should be like is beneficial. Cold turkey may throw one in the ruts of visual recovery. At the same time, incremental improvement may be observed by removing 20/40 glasses and staying without them for a while (the lens relaxes).

One another note, you didn't respond to Larry Bickford's and my blasting of your claims about the benefits of exercising the extraocular muscles. As I said this belief stems from the sheer ignorance of anatomy.

To recap, recovery from myopia involves two main strategies: plus lens therapy and restoring emotional balance.

Dawn

I'm sorry the information so far on Vision Care is somewhat lacking; I'm trying to find out more. Just now all I have is the recommendation from a Singaporean colleague who says how good it is.

Yes, it is a sliding eye chart but I don't know why you'd need a salesman to change part of it. I think he was needed to supply the new slide rather than to do the change itself but that's just a guess.

Caroline

From: Dawn Isaacson

What kind of machine is this?

A few posts ago someone wrote about a plastic slide machine that would do the same as an eye chart...is that it? If you need a salesman to change something on it, it must be more complex than that?

Dawn

Thanks a lot. I'll await your computer program news with great interest, as I'm sure everyone else will.

Caroline

On the other hand, there will be some computer programs coming out that, while they're not exactly the same thing, can work your eye in the same manner. As soon as I find some info, I'll send it to you!

Thought this was a useful summary - any information on blue-green light therapy's usefulness? I haven't heard it discussed on the list....

>From <http://www.cia.com.au/vic/faq.html#NA16.6>

[16.6] What is an example program for myopia?

Relaxation and passive work. Meditation. Yoga. Body work such as Feldenkrais if you posture needs reconfiguring. eg if you lean too far forward.

Palming. Brock string exercise. Select favorite exercises for: Extending accommodation out into the blur zone. Work on saccadic motion. central fixation.

Stretch muscles of the eyes. Breathing and blinking. Massaging around eyes, acupressure for stress relief.

Address the emotional aspects of withdrawal from far vision.

Blue-green light therapy. 15 minutes a day.

Wear no glasses when possible, use fitness 20/40 where full correction is not needed. Only wear glasses where absolutely needed.

Pay attention to nutrition. supplement Vitamin A/Zinc, Calcium/Vitamin D, B-complex, Bilbery. Avoid processed and refined foods. Minimise sugars, animal fats, stimulants and drug use.

Thanks Art. I think I may, at some point, follow suit and stop going. The big problem is the same as everyone else's: finding a dr who will prescribe weak glasses. Both my regular optometrist and ophthalmologist won't at all. Adamantly. But since you guys recommended the drug-store plus lenses, I can control the improvement myself.

BTW: I think I mentioned earlier that I was referred to this dr with the accommotrac by a PRK surgeon. He seemed to believe that the best the accommotrac would do is 1 to 2 diopters. The way I see it, it's better than nothing!

Thanks, Kip. Does this suggest that wearing pinholes over the training glasses (it's a feat, but like Cheryl I get desperate sometimes) is just as effective? According to your post, it sounds like any use of pinholes would be more effective?

Yes, I thought that Bates explanations, using western concepts of anatomy etc, for the usefulness of palming and swinging were weird. But then after reading a few books on Eastern traditions and seeing the similarities between the Bates method and therapeutic modalities working on an energy level, he made more sense. When I first heard terms in Chinese medicine like a dampness in the spleen or the triple burner, which doesn't correspond to any organ I learned about in anatomy, that seemed weird too. Chinese medicine and western medicine use the same term, the spleen, but they are really not talking about exactly the same thing. It took me a while to get away from a literal translation to an understanding of the concepts of meridians.

Originally I thought they must travel along nerves or lymphatic but they don't.

For example, the palming. If you just need darkness to relax your eye muscles, why palm? Why not cover your eyes with a sleeping mask or black bag? Bates recommended palming. Palming could be just another way, like acupuncture, accupressure and massage, to open up those meridians around the eye. Bates explanations for the mechanisms of why his method work did not make sense to me me. Neither did Chinese medicine at first. I prefer to think of some of his techniques as working on an energy level and I do not think he addressed that as a possibility at all. I hope that makes it clear what I meant by his method seeming weird.

This note and Kip's (addressed below) stimulated some thoughts.

>From my point of view, the question may be more emotional than physiological. (Philosophical underpinning: The physiological is malleable or subject to alteration by means of intent/will/mind/energy/whatever-you-want-to-call-it.)

I think it may depend a great deal on personal circumstances and how well one is able to move through depression. Boosting one's morale can be much easier when there is a whole-hearted commitment. The next several paragraphs focus on the emotional dimension. I return to the physiological below in response to Kip's note.

Here's what I've been doing:

I improved moderately over a 2 - 4 year period wearing 20/20 correction. I went in few reduced 20/20 lenses

when I began having more frequent headaches and eyestrain.

About 3 months ago, I switched to 20/40 during the day and 20/20 while driving or playing at night. Over this time period, improvement has been very slight and unstable. On a good day, I can see 20/20 with the 20/40 lenses, but not as often as I would like. When I put on the 20/20 lenses, I enjoy the clarity like looking at a good painting. When I take off glasses altogether, I enjoy the rest and I feel I can see very well, even though it happens to be blurry. In other words, I don't have anxiety about my visual field as long as I do not feel like I'm in a dangerous situation.

To make this story relevant: I feel that the reason I do not go cold-turkey is my lack of ease when working, driving, or going into dangerous situations without glasses. On the other hand, as alluded to above, I enjoy putting on the 20/20s from time to time to experience the clarity. This is also emotional in that I get a great deal of satisfaction from observing the lines, forms, colors, and feelings of this universe.

To think strategically: If I want slow improvement, I'll do 20/20 or a 20/40-20/20 mix along with VT techniques. If I'm ready for faster improvement, I think cold-turkey with a lot of time for silence, experiential exploration, creative expression, and VT/meditation is the way to go.

Earlier, Kip Bryan wrote:

> Your eyes need good contrast (edges) to focus correctly. (If you look
> at a blurry picture your focus naturally drifts toward your TA).
> If you're myopic, you see in a blur. This blur reinforces itself
> since you have no good contrast (no clear edges) to use to get your
> focus right.

This can be remedied by occasionally looking at things close up. Thus one can give oneself unlimited clarity.

FYI

I got this out of David Eisenberg, M.D.'s book Encounters with Qi. In 1980 he spent a year studying traditional Chinese Medicine in China as a medical student. He went back the next year with one of his professors to find out more about Qi Gong. This excerpt comes from the section about that trip, pp202-203.

"After tea and preliminary speeches, Dr. Guo and Dr. Ni reviewed a study they had performed on a Qi Gong healer said to be capable of emitting external Qi for therapeutic purposes. The experiment involved children with severe myopia (nearsightedness). Eighty myopia children ranging in age from twelve to fifteen were selected at random from the ophthalmology clinic. Each child underwent a thorough eye examination, including a precise measurement of vision, anterior chamber dimension, and corneal curvature. The natural course of this condition, myopia, when studied in children suggests that vision typically stays the same or gets worse and rarely improves spontaneously. This is because nearsightedness has to do with a defect in the curvature of the eye itself. The eighty children selected for this study were divided into four groups. The first group received no treatment. The second received placebo eye drops. The third was instructed in the practice of Qi Gong, the exercises being similar to those used for adult hypertensive patients; the children in this group attended classes for two weeks. The fourth group was treated by the Qi Gong master, who spent twenty minutes a day with one hand in front and one hand behind each child's head "emitting external Qi" in the direction of the eyeballs.

Dr. Guo and Dr. Ni proceeded to cite the findings of the study. Of the nontreated and placebo groups, none of the forty children had improvement of vision after two months. Of the twenty children who were taught Qi Gong exercises, two showed improvement in vision of the basis of multiple visual

criteria. The research group speculated that so few had improved because the children were too young to concentrate on the meditative aspects of Qi Gong.

Of the twenty nearsighted children treated by the Qi Gong master using external Qi, an astounding sixteen showed marked improvement in vision. This was again confirmed by multiple visual criteria. The ear, eye, nose and throat staff admitted they were baffled by these preliminary results."

i'm still pretty new to vision correction...but i don't understand something...as i understand it, the optimal condition to improve myopia is to be focusing on distant objects that are just out of focus but can be brought into sharper focus with effort, thus strengthening the muscles of the eye. if this is so, why are we trying to push everything way out of focus by wearing plus lenses when most mild myopes see things at a distance as slightly blurry with their natural vision??? i have experienced immediate (if temporary) improvement by wearing plus lenses, but i don't understand why this extremely blurry condition causes more of an improvement than my normal, slightly blurry condition that would be seen preferable...

i might be missing something obvious here, but i would appreciate any clarification that anyone could offer....

I tend to view it this way:

The eyes become myopic in the first place because of some kind of imbalance in your life (for example, too much stress from studying.)

The body may relieve that stress by unbalancing your visual system and blurring your vision. This is a feedback mechanism. If the stress is removed, or alleviated by proper rest & relaxation, the blur will go away, naturally.

However, if the stressful situation is not removed but instead

intensified, the blur may not go away, or become worse.

If the feedback (symptoms of blurry vision) is instead removed by prescribing corrective lenses (which I now regard as a powerful, addictive drug.) The original problem which produced the blur is not addressed, it is ignored. So the body continues the vicious cycle, making the vision ever more blurry and requiring ever stronger prescriptions to block out the problem.

While you are using your drug (wearing your glasses) the body is not aware it has a problem, because it sees clearly.

Simply by removing your glasses, the body is again aware of that feedback, and can then take steps to repair itself, naturally.

Plus lenses (which I do not advocate or wear, BTW) work on the principle of applying the opposite stimuli to reverse the stimuli of negative lenses. I view this as using another drug, which gives you stimulation in the opposite direction (e.g. telling your body that things are even further out of whack, so that it will more speedily revert to normal through its natural recovery mechanisms.)

Using a reduced prescription, is kind of like a smoker gradually cutting back on cigarettes in order to quit smoking. In that vein, the cold turkey analogy makes a lot of sense.

It is very hard to quit cold turkey because we are so dependant on our glasses just to function normally in our day to day activities. I have noticed that I can see much better the longer I go without the corrective lenses, and it sucks having to go back to wearing them after a long period of not wearing them, but I cannot yet function completely well without them for working/driving.

Based on what Linda & Bates have said (Linda of Baby Mode fame- a key step for her was complete abstinence from glasses. BTW are you still here on this list??) and from what I have seen (literally too) I am convinced that complete abstinence from glasses is a KEY step!

I am looking forward to going without my glasses for a couple of weeks straight this holiday season, when I don't have to work.

I'm new to vision therapy too, but I've been doing a lot of research on the topic. So far, I haven't found anything in print advocating wearing plus lenses. Anybody know where this concept comes from?

I noticed in one of Julie's post she mentioned:

>For example, the palming. If you just need darkness to relax your eye
>muscles, why palm? Why not cover your eyes with a sleeping mask or black
>bag? Bates recommended palming. Palming could be just another way, like
>accupuncture, accupressure and massage, to open up those meridians around the
>eye. Bates explanations for the mechanisms of why his method work did not

I checked in one of the books I just bought on improving your eyesight and it says about palming...

"A pranic healing magnetism flows from your hands into your eyes. The warmth increases the circulation. Fifty-four times a second the eyes are washed by a specialized blood stream. This is doubled during palming. The retinal nerves are nourished, venous blood carries away the poisons in the eye, and the arterial blood brings fresh nourishment. The importance of this increased blood and life-force circulation cannot be over emphasized. It is extremely beneficial for the entire body...When the eyes are healthy, they act as channels through which pranic light and life force from the very atmosphere flow into and vitalize all the body cells. The hands are also such channels. Combining the two channels through palming is doubly effective for flooding body cells with high- voltage pranic light. To sit in a dark room with your eyes closed is not a substitute for palming. Neither is placing a dark cloth over your eyes. Neither provides the incomparable power of contact with human hands."

I also remember someone on this list saying they had problems with night vision? The book mentions that too...

"There is purple pigment in the retina called visual purple. This is used in night driving, for example. Light tends to absorb this element, but

palming restores it. If you are having difficulty with night vision, try palming."

Excerpts above are from the book:
"The Eyes Have It", By Earlyne Chaney,
ISBN 0-87728-621-3, USA \$9.95

I noticed in the Natural Vision FAQ (mentioned in previous posts), it says that palming comes from the Hatha Yoga traditions. But then the FAQ does not elaborate on that point.

BTW I downloaded a bunch of info about Qi channels from the Net at:
<http://acupuncture.com>

I haven't read it yet.

Aren't I supposed to be cutting down on my reading?!

one other reason for palming tho Bates may not have been aware of it is that we have chakras, or energy centers, in our hands and joints as well as along the spinal cord. check out a chakra workbook by judith anodea and what i was just grooving especially upon: Anatomy of the Spirit by Caroline Myss, PhD.

eileen

ps for the newcomers, i started at -9.50sphere and -3.50 cylinder. and am now down to -7.5 s -1.75 c. i was using Lynette Scholl's book entitled HYPNOVISION. I got it out of the library. apparently it is out of print now. it involves daily guided relaxations to put your mind in alpha mode, and a sequential program of positive thinking, accupressure, massage, visualization, palming, swinging, sunning, near-far stuff, focussing... i haven't finished the program ... i started about 2 years ago and have plateaued. In the meantime, i have been in graduate school and doing a lot of emotional learning due to weird stuff. so yes, it is all related. I have

a terrific optometrist who happens to be female who'd never heard of this but was fascinated. After i'd dropped 2 diopters in 2 months, and gone thru 2 pairs of glasses, she suggested we split my prescription into contacts for the myopia and overspecs for the astigmatism. this works well because i can take the overspecs off and still be legal to drive with my -7.5 soft lenses.

only thing is, after this i stopped changing. partially cos i slacked up on the zeal with which i used to do the twice daily stuff, partially cos other things became important , probably more so than the eyes... i look at it all as a continuing process, and i am still convinced that i will

obliterate my need for glasses in this lifetime, without surgery.

so now i am planning on ordering a set of contacts .50 less, and getting back in the program, maybe starting over (the book has scripts for each section, which i made cassette tapes of using my own voice. i found that i function very well with structure.

ciao for now.

Herbert, I have met with skepticism from both male and female, professional and ordinary person alike. The ophthalmologist that so kindly and without question reduces the perscription on my disposable lenses is male.

I think the training/conditioning has more to do with it than gender :) "New" ideas require getting used to. I used to think people would stick to the same opinion, but have found that a little time and exposure work wonders in opening minds. Also, folks that have a good deal of self confidence seem less likely to be reactive, and more likely to be open and interested. Also, might not a myope be more defensive about a fellow myope doing vision improvement? Perhaps finding a far-sighted eye doc (are there any of those?) would solve that problem?

To those who are still wearing contact lenses: The nature of contact lenses forces your eyes muscles to maintain and conform to your prescription without any breaks. They hold the eyes to that constriction. Glasses at least give your eyes a break as they dart around. It is my understanding that with glasses, the strongest part of your prescription is in the center (or maybe related to that PD number). So when you are not looking exactly through the middle, your eyes get a break. In addition, it is much easier to take off your glasses for a few minutes and then put them back on, then it is to do the same thing with contacts. Once again allowing the muscles to relax some. Whatever your rationalization is about having to wear contacts (vanity maybe?), get over it and get some glasses to use in your vision quest. The rationalization more than likely has something to do with why you blurred and/or distorted your vision to begin with.

I wore contact lenses for 30 years. Once I went to no glasses and reduced lenses and other stuff, my prescription has dropped to less than half of what it was 2 years ago AND no astigmatism.

Blessings, Cheryl

Eileen,

A.

Were you wearing contacts during your period of dramatic improvement? I'm wondering if wearing contacts may be a contributing factor to a steady visual state. When I wore contacts many years ago, my eyes were very stable, going neither up nor down in their prescription. Because of that experience, I have an aversion to contacts, since I seek continued improvement.

Let us know how you do on the .50 less contacts over time.

B.

I'd like to hunt down a copy of Hypnovision. Could you send me the full title and ISBN number along with the date and the publisher? There was a note several days ago that referred to a book by the same author with a different spelling for

the first name: "Lisette" instead of "Lynette"
(or maybe I copied it down wrong). The title
was _Visionetics: The Wholistic Way to Better
Eyesight_, 1978, ISBN: 0-385-13279-4.

+Mark

Art, I agree with you. Plus lenses are not necessary and, I think, undesirable in VT. I think we're in the minority in this list along that thought. Everyone I've heard of who has gone from minus whatever diopters to 20/20 has done so WITHOUT plus lenses, and I'm glad you mentioned Bates and Linda who are examples. If minus lenses are like someone using a cane to help them stand, plus lenses are like the same person holding onto a rope. The eyes/mind need to learn on their own how they should be seeing and observing.

It is only logical that plus lenses will hurt your near vision if minus lenses hurt your distance vision. So I think people using plus lenses as VT therapy should be on guard for their near vision. The temporary clarity that the eye gets after using plus lenses is just that - temporary. If you want to induce that clarity again, you've got to put on the plus lenses.

What messages are you giving to your eye/mind vision coordination? How will you "learn to see" on your own?

Tim

>

>My dr prescribed plus lenses for a few reasons: At the -9.00 stage, it's SOOOO difficult to go cold turkey. The plus lenses, over my contact lenses, are a way to lessen my frustration but yet halve my prescription. My therapist also recommended periodically wearing the plus lenses without my contacts, probably like someone else mentioned (sorry, I don't remember who) to push my vision in reverse & tell my system to correct the other way.

>

>Another reason for the plus lenses, as far as I understand it, is that when you're very myopic and wearing corrective lenses, the correction is for distance, not near. By wearing a small amount of positive correction for reading close, I think it's supposed to relax the muscles which would normally strain to make the change from far to near. When I went to see the PRK surgeon who referred me to the doctor, he said pretty much the same thing. He even talked about giving people monovision (that is, one eye sees close, the other sees far--he would give people 20/20 in one eye, then 20/40 in another for them to see close) on purpose when they did the surgery: I think the reason is that the surgery is the same as corrective lenses: it cures the symptoms but not the cause.

>

>I have two prescriptions of plus lenses I'm working with: a +1.00, which I wear over my contacts when working on the computer or reading, etc; and a +3.00 that I wear whenever I can. (I also have a -5.00 for when I don't have my contacts on. And when I get frustrated with them, I put the pinholes over them. Yes, it does get confusing.)

>

Hi,

I'm a new subscriber to this list, although I've read through some of the archives. I've read through some of the Natural Vision FAQ 1.1, but I still have questions regarding my own situation.

While I have deliberately never worn glasses, I do have a prescription (from a couple years ago) and glasses. My right eye is my dominant eye. My visual acuity in my right eye is, IIRC, -1.5, however, my left eye is at +1.5. Both eyes have astigmatism. I have never been able to see stereograms. They're just a bunch of dots to me.

Most of the training and exercises in the FAQ (and elsewhere) seem to make the assumption that the vision in both eyes is the same. Might there be any special exercises I could do to account for this?

Also, I read through the info (what there is of it) on the Vision Freedom page, what do you all think of it? Has anyone tried it? Might it be useful for someone who has never worn glasses?

(Actually, I lied -- I have worn the glasses, but only for about 5 minutes before they bothered me enough to take them off).

Thanks,

--

David Sward

I had gotten the literature from them on Brian's kit and then I found a friend of mine had got the kit. She let me look at it. The book of instructions with it were not very well done - lots of sales/marketing type statements - definitely needed a good editor. The information seemed to be basically plus len therapy. You practice focusing up to 2 hours a day with several different or combination of plus lenses which come with the kit. It wasn't as simple as just reading. You were supposed to keep pushing the reading material away from you so that your eyes would have to work at focusing. I couldn't see any advantage to the kit over what materials I already had to use in my vision therapy.

so plus lenses hurt your near vision???? this is so frustrating.....when i was in track in high school, the coach used to say "if you want to run fast in the race, run fast in practice. if you want to run far in the race, run far in practice." weight lifting coaches say "if you want to lift heavy weights in meets, lift heavy weights in practice..." maybe it would follow that if we want to see good far away, we should just look far away as often as we can.....

what do you all think???

jeff

Mary:

The average person in optometry school at Pacific is a moderate myope. 75% of the students are myopic, much higher than national average of about 25%. Of course, the higher the educational level, the higher the prevalence of myopia, but optometry is even higher than expected for graduate/professional school in general. So the hope of finding a hyperopic OD is less than or equal to 25% I'd say offhand!

My experience has been that spending more time in the sun improves night vision. I believe the reason is that exposure to bright light STIMULATES the production of visual purple (precisely because it depletes it), which is used for both day and night vision. I remember reading somewhere that the same substance forms the basis for both day and night vision and a subtle chemical reaction changes its receptive qualities. I hope some of our ocular physiologists on the list can help me here.

initially, yes, but then i sort of alternated between the full eyeglass prescription and wearing soft lenses that corrected the myopia only. it only took a month and a little to drop a diopter, and my optometrist had never heard of this before... she asked why i was in, since i wasn't due for a check up for another 8 months (i usually go once a year, and i've had the same prescription since i was 3 years old)... terrible headaches, blurred vision, and i think i need new specs , i said.
it's interesting, actually, because it was a very stressful time in terms of health, i was working nights and recovering from knee surgery, but in retrospect (because of a former i-see poster named elena) i went back and checked my journals to see what factors i may have overlooked, and in fact, one thing i did consistently THEN but do not do now is ... yoga.
i used to study with a modern dance company, and during rehab yoga was the "only" thing i could do, with a little swimming, and as soon as i could go back to dance class, the yoga went out the window. and i got fired up about doing it again after i had read elena's posts, but i've been in

graduate school and it's so easy to put stuff like that on the "i'll fit it in ... soon" list, and of course it doesn't get fit in. but now things in life are making it seem a total necessity, so it's gotta get on the "you have no choice" list...

I'm wondering if

HYPNOVISION : The New Natural Way to Vision Improvement
by Lisette Scholl
c 1990 Henry Holt and Company, Inc
ISBN 0-8050-1133-1

> the first name: "Lisette" instead of "Lynette"
> (or maybe I copied it down wrong). The title
> was Visionetics: The Wholistic Way to Better
> Eyesight, 1978, ISBN: 0-385-13279-4.

yes, sorry, *i* made the booboo, it is lisette.

Visionetics is her earlier book,
and interestingly enough in the preface she thanks an OD named Ray
Gottlieb who is living in Rochester at this time... a friend of mine made
an appointment to see him and invited me along, he had all kinds of neat
toys in his office. this friend succeeded in adjusting to a lower scrip
than he had previously been wearing but it is not as important to him at
this time to tackle this stuff with gusto.
there's another guy here in Roch that does vision therapy, but he works
mainly with kids, and mainly with muscular things, and i did have one appt
with him but he did not seem keen on the idea of someone doing this

"without guidance"... i did not get a comfy feeling with him and decided that if i could achieve what i already have on my own, there was no reason not to keep on going.

I happen to be in the grad program for Medical Illustration at RIT, and would like to make this stuff the topic for my thesis, so i will be writing to folks to try and get some advisors/advice... whatever i find out, i will be happy to pass along.

eileen

ps i followed up on elena's suggestion and looked at arthur janov's more recent books... very good stuff. and i can't stress enough what an astounding pool of wisdom Caroline Myss has put together... i was listening today to the tapes entitled "Why People Don't Heal"... it's too fresh in my mind to start paraphrasing, but check it out... i got them from Barnes and Noble bookstore for 20 bucks and they will change your entire worldview.... health, emotions, physics, energy science, spirituality... all rolled up in an astounding package of unity.

bla bla bla

enough pontificating for today. ciao.

OK, let's have that other discussion! Yes, I did think that the ciliary muscle is most relaxed when you see far.

> Normally, there is a connection or "loop" between your vergence (two eyes

This brings up a question of mine. The purpose of wearing plus lenses is to simulate far vision during close work. However, the use of plus lenses alone does not fully simulate far vision. They eliminate accommodation, but not convergence and stereopsis. Normally when you look at something close, your eyes must accommodate and converge.

So the question is, is it necessary to eliminate convergence for therapeutic purposes? If you don't eliminate convergence, does the "loop" prevent complete relaxation of accommodation?

This is the theory behind Donald Rehm's [The Myopia Myth] "Myopter Viewer". It eliminates accommodation, as well as convergence/stereopsis. Is this

really necessary, or are plain old plus lenses good enough?

I haven't used pinhole glasses as therapy, no, but I have seen a number of references to them. Some vision professionals are very proud that pinhole glasses cannot be sold in their states. It took some work to get them banned.

I've seen them used even by researchers writing in vision research journals. The idea is that when you look through a pinhole, your eye can be focussed anywhere (accommodated near or far) and you still see a clear image. So, your ciliary moves to its tonic of accommodation (TA) position (dark focus) where it's most relaxed. (I know many people think that it's most relaxed when you see far, but that's another discussion.)

Normally, there is a connection or "loop" between your vergence (two eyes pointing to a nearby object or pointed more parallel for a far object) and your accommodation. However, when wearing pinhole glasses, this "loop" is open (the loop being the two-way connection between vergence and accommodation, each one reinforcing the other).

I forget what they're studying in this case, other than how vergence works when not affected by accommodation. They also make the vergence "open loop" by disconnecting any common field of view between the two eyes (much as Kaplan's two-eyed patch does).

Here's a plausible (to me) explanation for how pinhole glasses could help improve myopia (similar idea could apply to hyperopia or presbyopia):

Your eyes need good contrast (edges) to focus correctly. (If you look at a blurry picture your focus naturally drifts toward your TA). If you're myopic, you see in a blur. This blur reinforces itself

since you have no good contrast (no clear edges) to use to get your focus right. If only you had some help to make the edges just sharp enough that you could use your natural focus control to bring the edges the rest of the way into clear focus, you'd be all set. Once it's in clear focus, you could perhaps reduce the "help" and keep in focus (since the edge is now clear enough to reinforce your focus on it.)

There are a number of ways to get this "help":

- bright light naturally increases the contrast
- Bright light also shrinks your pupil size which increases your depth of field (just like f-stop on a camera)
- squinting
- wearing pinhole glasses with the right size holes for the brightness level around you.
- bring the subject (eye chart or whatever) near you, then you can push it back gradually once it's in clear focus.
- blink your eyes, so a layer of tears forms over the cornea, which effectively polishes the surface.
- look through an insect screen at just the right distance so your eye focusses on the screen rather than at your TA, thereby (perhaps) making distant objects more clear.

You use "just enough help" so you get to practice going the rest of the way into clear focus, and presumably learn the muscle skills just as basketball practice helps you shoot more hoops. As you improve, you would need lower light levels or larger pinholes.

Some pinhole glasses references on the web:

<http://www.livelinks.com/sumeria/health/raids.html> (about FDA raid on Natural Vision International (NVI), confiscating pinhole glasses)

<http://www.ftc.gov/bcp/adcon/adconpro.htm> (about fraudulent advertising, includes: "I guess all of you remember pinhole glasses. They were the glasses that had the little holes in the lens and they were supposed to increase your energy level and your cognitive abilities. If you have a question about these glasses, I encourage you to call the FDA Center for Devices and Radiological Health.")

> be brought into sharper focus with effort, thus strengthening the muscles
> of the eye.
```

Not exactly. The ciliary muscle contracts to adjust the lens of the eye for close work, (e.g., reading). This is called accommodation. The same muscle relaxes for far work. Note as the name suggests, the eye muscle must "accommodate" to near vision, i.e., far vision could be considered its "normal" (relaxed) state. The problem is that excessive close work causes excessive accommodation. This leads to ciliary muscle spasm, which means the eye becomes chronically adjusted for near vision.

The purpose of using plus lenses is to eliminate accommodation, i.e, relax the ciliary muscle. This way when you are reading, your ciliary muscle does not have to accommodate, if you have the reading material at your far point.

```
if this is so, why are we trying to push everything way out
> of focus by wearing plus lenses when most mild myopes see things at a
> distance
> as slightly blurry with their natural vision???
```

I really don't think that walking around looking into the distance with plus lenses helps much. What does help is reading with plus lenses. Like you said, at a distance, a myope already sees blur. The purpose to plus lenses is to simulate far vision while doing close work.

In a message dated 96-11-20 09:41:28 EST, marif@btigate.com writes:

> I'm new to vision therapy too, but I've been doing a lot of research on the
> topic. So far, I haven't found anything in print advocating wearing plus
> lenses. Anybody know where this concept comes from?

It is a very sound scientific concept. Professors of Ophthalmology for major universities advocate the use of plus lenses. There are numerous books, but the one that gives the best explanations that I have read is the following:

THE MYOPIA MYTH; The Truth About Nearsightedness and How to Prevent it.

By Donald S. Rehm,
International Myopia Prevention Association
RD 5, Box 171
Ligonier, PA 15658

(\$15 including S&H)

Best 15 bucks I ever spent!

In a message dated 96-11-20 12:39:11 EST, Tim.Patterson@cciw.ca (Tim Patterson) writes:

> Everyone I've heard of who has gone from minus whatever diopters

My roommate has went from -4.75D to -2.75D in less than 6 months using plus lenses as his ONLY therapy. Another pilot friend has went from -1.50D to emmetropia by using plus lenses ONLY.

>If minus lenses are like someone using a cane

clarity
> that the eye gets after using plus lenses is just that - temporary. If
you
> want to induce that clarity again, you've got to put on the plus lenses.
> What messages are you giving to your eye/mind vision coordination? How
> will you "learn to see" on your own?

IMHO, there is no scientific validity to the above statements. As a pilot, I am a math and physics kind of guy. I need hard science and proof before I believe something. Some will tell you that myopia is your body telling you "something is out of balance". Whatever.

re: i don't understand...

Myopia is simply your eyes mechanism of adjusting to its average visual environment. There is no doubt that your eyes DO adjust to their average visual environment. (See the vision related PhD theses on this web page): <http://www.vthrc.uq.edu.au/vthrc/Theses/Theses.html>

Excessive close work skews your average visual environment to something closer than optical "infinity". Plus lenses during reading helps you skew the average back to "normal". It works, no doubt about it.

Plus lenses cannot hurt your close vision. Even doctors who don't think plus lenses will help will tell you that it can't hurt. (The condition in later life that affects close vision is presbyopia, which is in no way caused by plus lenses!)

i'm still pretty new to vision correction...but i don't understand something...as i understand it, the optimal condition to improve myopia is to be focusing on distant objects that are just out of focus but can be brought into sharper focus with effort, thus strengthening the muscles of the eye. if this is so, why are we trying to push everything way out of focus by wearing plus lenses when most mild myopes see things at a distance

as slightly blurry with their natural vision??? i have experienced immediate (if temporary) improvement by wearing plus lenses, but i don't understand why this extremely blurry condition causes more of an improvement than my normal, slightly blurry condition that would be seen preferable...

i might be missing something obvious here, but i would appreciate any clarification that anyone could offer....

That is an interesting point, individuals who have a higher level of education, increase their possibility of developing or acquiring myopia. These are statistics taken DR. Jacob Liberman's book *_Take off your glasses and see_* :

Age or Education Level	% Myopic
-----	-----
At birth	less than 1
age 5 to 9	3
age 10 to 12	8
end of grade 8	20
high school grad	40
college grad	60-80
graduate students	80

These studies were taken from Theodore Grosvenor's The Results of Myopia Control Studies Have Not Been Encouraging "Journal of Behavioral Optometry, vol 4, no.1, pp 17-19.

Interesting concept, although, I don't believe that looking farthur is the answer, instead of looking at the world, let the world look at you, This helps to relax the eyes and the mind.

Have fun,

-Peter

In case anyone else is interested...

From: thecount
To: Richards, Caroline

I noticed on the Internet that you have an interest in vision improvement. I would like to make you aware of my company's natural Vision Therapy Program. We have been distributing the program for about eight years, improving it along the way.

Our Basic Program is designed to allow people to improve their vision naturally at home or office, at their own pace.

The program was developed by a group of Optometrists and Ph.D's and it is based on four simple premises that have worked for hundreds of people that have used the program. They are as follows:

1. Exercises that strengthen all of the eye muscles, and improve circulation to the eyes so that nutrients can aid in their development.
2. Consume proper nutrients via a good nutritional diet

3. Develop a positive attitude towards the idea of good and improved vision

and use the power of the mind towards this end.

4. Learn to eliminate stress and relax, since stress taxes all our bodily functions

especially the vision system.

Our program consists of a vision improvement kit that includes two professionally

done videos that show all of the exercises and techniques. Also included are vision

aids, charts, and an informative pamphlet, and an announcement on several new

nutrition breakthroughs. We have conducted classes using the program with very good

success and over 50,000 do it yourself programs have been sold.

We have a brochure that describes the program in more detail. Should you want it

please E-mail your address to me and I will send it to you.

If you would like to order the complete Vision Therapy Kit the cost through December

is \$29.75. Normally the price is \$50.00. plus tax. If you live in California, please add

sales tax of \$2.10 and shipping charge of \$3.00. Total charge is \$34.85 in California

and \$32.75 out of state. There is a 90 day money back guarantee if you are not satisfied.

Mailing address for orders - Vision Therapy Inc.
2059 Camden Ave.
#119
San Jose, CA 95124

Anyone got any evidence to counter that?

>It is only logical that plus lenses will hurt your near vision if minus
>lenses hurt your distance vision.

I also have wondered what plus lenses do to your near sight. I presume that nobody on this list using plus lenses has suffered a deterioration in their near sight? Can anyone show that their near sight is still ok in spite of plus lenses?

> What messages are you giving to your eye/mind vision coordination?
I get eyestrain using plus lenses, which someone explained as possibly being related to a difference in the convergence/divergence required for the accommodation being used, compared with what you normally experience.

Obviously you could use plus lenses in conjunction with patching, but is there a danger of causing difficulties with convergence/divergence if you don't?

My behavioural optometrist told me that +3 lenses were 'too strong' for me and that I should not go above +1. Since my eyes are only -0.25 and -1.0, that would imply to me that nobody (well, hardly) should go above +1.

I didn't get to ask him why but I will forward his answer when I next see him. (Any guesses in the meantime would be welcome).

Too stong for "what"? That's the question. It depends on the distance at which you are looking. The focal length in meters of a lens is the reciprocal of it's power in diopters. For example, a 3 diopter lens has a focal length of 1/3 of a meter. If you were an emmetrope, and you held book at 1/3 meter while reading, a +3 diopter lens would allow you to read without accommodation. The eyes would receive parallel rays of light as if from a far-distant object. This is called reading at the far point.

If you were -1 diopter myopic, than a +2 diopter lens would allow you to read at the far point when the reading material is held at the same 1/3 meter.

If you normally hold the book farther away than 1/3 meter (about a foot), than you would use a lower powered plus lens. If you hold your reading material at, say 16 inches or so, you might need a +2.50 diopter "add".

It's really just simple mathematics and physics, once you understand the basics.

Speaking purely subjectively, and non-medically, I find that in deepest winter, when I spend much more time indoors, and when there isn't too much light about anyway out of doors, my general eye health feels worse.

As mentioned before, I believe my `_distance_` vision has suffered as a result of regularly using reading glasses (both for reading, and

computer monitor use. (However, I was not myopic to start with; the deterioration in distance vision could be as a result of the presbyopia which forced me into reading glasses in the first place, but I doubt it somehow, that is, it may account for some deterioration, but not this much.

Jeff wrote:

>so plus lenses hurt your near vision???? this is so
>frustrating.....when i was in track in high school,

What I do is get all the info I can on the topic and then go with what feels right for me.

1. Plus lenses. I went to the local Kmart store and tried on a bunch of different reading glasses. I'm assuming that these are the plus lenses everyone is talking about. I was totally turned off. I have enough blur, why do I want *more* blur (and stress) ?? So for now, I'm not going to get into plus lenses.

2. Pin hole glasses. Since I'm new to this vision therapy stuff, I've been just observing and learning about how I see without my glasses. I'm learning a lot by playing around with an eye chart. I was palming and massaging my eyes and I noticed when I had my hands up by my face (like blinders on a horse) viola! I can see better! Then, I punched a hole in a piece of paper with a hole punch and looked thru it. Better. Then I punched a smaller hole in a piece of paper with a fork tong (hey, that's what was handy) and looked thru it. viola! I can see better! Now I'm definitely going to check out this pin hole glasses stuff.

I get very excited when I can see things clearer without my glasses. That gives me hope that my eyes really do have the potential to see better and that this vision therapy stuff can really help.

And lately, I've been feeling a bit angry at my eye doctor, who for years has happily made my eye glass prescription stronger, and stronger, and

stronger...never even mentioning that there might be alternatives. And these people are supposed to be the eye experts? I don't have a degree in optometry. I don't know all the technical theories, blah, blah. I do know that my deteriorating eyesight has got to stop! I'll eventually be legally blind if this continues. And my eye doctor is not helping me...

Thanks for letting me rant a bit...I feel better now. :-)

~Mari

I find my night vision has improved since I started sunning. I also notice less after-image when I happen to get a bright flash of light in my eyes, such as glare off a mirror.... I live in south Florida (sub-tropics), so I get a LOT of sun.

My guess is that my body has responded by becoming more adept at producing visual purple, because it has to. Also, seems like the visual purple would always be fresher, like going to McDonalds at lunch rush :) I'll bet someone on the list knows....

On the other hand, Dawn, you may have something there. Most women who elect to enter into health care professions do so in a support position, perhaps *because* they're aware (either consciously or not) that they have a knack *for* that support, and that it's easier to give as an assistant (I have had similar experiences and know what you mean). My ob/gyn is a woman, and aside from being the only female doctor I've ever LIKED (ALL the others GP and ophthalmologist, etc.-- were *particularly* dreadful at the human side of things), she is the most *wonderful* doctor of any sort that I've had. I don't know what it is, but maybe it has to do with the sort of personality

that might incline a woman to become a doctor, or maybe the training does something particularly nasty to them.

In any case, there are such vivid differences between males and females it seems reasonable to me that you're not imagining things. Who knows what happens out there?!

Though I haven't used them much in the last month, I used plus lenses (+2.00, +2.50) for reading and computer work over my reduced powered contact lenses for about 10 months. My reduced lenses presently are -3.50, and I am more often going bare eyed (that is why I use the plus lenses less often). When I first used plus lenses, I wore -4.25 reduced perscription contacts with them for reading/computer. The optometrist I saw would have put me in -6.00 lenses, but I pushed for a lower script :)

When I wore +2's over -4.25's, it was like wearing a reduced script of -2.25 for close work. I found it relaxing, and my unaided reading distance has improved. I can read and even use the computer for the first time in many years! If, however, I had been farsighted, I would expect a decrease in nearpoint vision from wearing plus lenses. MINUS lenses would cause the farsighted eye to work on improving focus IMHO. It is a math thing.

The point in wearing plus lenses is to "push" a little beyond normal, like (some else on the list said) a wire, so that when released the gain is maintained. Seems a little like leverage - something to push against, until I get closer to where I was BEFORE minus lenses.

This has been my experience... vision improvement is not ALL mechanical for me, however.

I advocate plus lenses for prevention and recovery of myopia. I don't think it would have any affect on presbyopia (other than the fact you need them to read). Presbyopia is caused when the lens loses its flexibility and you therefore lose your ability to accommodate. Plus lenses could not negatively affect distance vision.

If plus lenses are causing too much blur than you are getting too strong of a lens for your viewing distance. You have to understand what your minus prescription is and how much plus lens "add" you need to eliminate accommodation for whatever distance you are from the reading/viewing material. If you are more highly myopic than about -3D, than you probably don't need plus lenses over the naked eye. You need either a reduced minus prescription, or wear plus lenses over your full minus prescription (same effect).

Pinhole glasses cut off the most divergant rays of light from an object in view. It restricts the rays to the center of the pupil. Since these rays do require as much refraction (do not need to be bent as much), any refractive errors in the eye do not affect the vision as much. So they are a way of clearing up vision without bringing accommodation into play, so that is a good thing. It's just a different concept than plus lenses.

I think we can all relate to that. I never wore minus lenses, but I wish my doctor would have told me how to PREVENT myopia in the first place! At least, after it started, how to recover from it rather than just saying, "You need glasses"!

I think that if you reduce your contact lens prescription periodically, you are better off than wearing glasses because I read that the focal point of the glasses forces you to stiffen your eye and move your head to see rather than your eye, which would aid in relaxing your eye muscles naturally. Simply looking from corner to corner and side to side at different levels after wearing glasses for a while feels good (like it loosens the eyes) and appears to confirm this theory.

Unless your prescription is not very strong, why would you not look through the part of the lens that allows you to see clearly? To not look through the focal point and "give your eyes a break" would probably require a lot of effort. The only advantage glasses appear to have is that you can take them off easily. So we contact lens wearers can use plus lenses and lessen the contact prescription. But with disposable contacts nowadays, changing contact lens prescriptions appears more practical (and maybe cheaper) than changing glasses prescriptions.

> Whatever your rationalization is about having to wear
> contacts (vanity maybe?), get over it and get some glasses to use in
> your vision quest. The rationalization more than likely has something
> to do with why you blurred and/or distorted your vision to begin with.

Vanity does not force me to wear contacts any more than wishing to correct my vision to not wear glasses. I don't like glasses because at -9.00 they are heavy, make marks on my nose, cause me to sweat & become more uncomfortable when they start to fall off, are uncomfortable to sleep in, and many, many more reasons. I prefer contacts because at -9.00, they actually correct my vision. Glasses at that prescription must be perfectly centered for my vision to be corrected.

On the other hand, wearing thick lenses that distort the picture of my face (negative lenses make things look smaller, positive larger) throughout my childhood and most of my adulthood has probably contributed to the extreme progression of my myopia. At a young age, I did not look like the rest of the kids, and when it came to sports, I felt almost "handicapped." I never wanted to hide my face behind those ugly frames and thick glasses, but I was forced to. In addition, glasses cause the world to be distorted in several ways, as does any reflective or clear glass that you look through: contact lenses do not cause the distortion in shape that eyeglasses do, and colors are not as distorted through contact lenses as they are very muted as seen through eyeglasses.

I resent the implication that vanity forces me to wear contacts but that vanity does not force you to correct your vision to not have to wear glasses. I have nothing to "get over with" and will continue my use of contacts until I have successfully removed the effects of years of wearing glasses.

> I wore contact lenses for 30 years. Once I went to no glasses and
> reduced lenses and other stuff, my prescription has dropped to less
> than half of what it was 2 years ago AND no astigmatism.
> Blessings, Cheryl

Soft contact lenses (at least the many brands I have worn over the years) do not correct for astigmatism and therefore do not cause your eyes to become more astigmatic.

If wearing glasses worked for you, I am happy for you....But unless someone has some scientific evidence that contact lenses (without getting into the cleanliness aspect) are inherently bad for your eyes or will prohibit vision therapy of the type we have been speaking, I will continue to wear my contacts. Well, anyone have some evidence for me & Cheryl? Contacts or glasses, or does it make no difference?

Thanks everyone!

Dawn 8-)

>When I look straight, my vision is worse than when I look up/down/over.

>Any thoughts on this from the group would be appreciated.

I read that the focal point on glasses adds to the myopic degeneration effect: in other words, when you look through only that point, which you would naturally want to do since you see better there, the eye muscles become even stiffer. According to one book, people that are highly myopic have a tendency to move their heads to see instead of their eyes. Kind of makes sense, if you think about any body part you might hold in one position for a long time.

Personal experience showed me that if my glasses weren't perfectly centered so that the focal point was where I needed it, at a high myopic state it drove me nuts 'cause I couldn't see well enough.

If your vision is worse when looking through the center, maybe your prescription is too strong? Another idea: I had an optomotrist who insisted on not putting the focal point in the center of the glasses, which

frustrated me to death (because I could only see through the focal point). This happened long before I ever heard about vision therapy.

>BTW, I used to wear contacts (soft, hard, all different kinds). I
>eventually got so I couldn't wear them anymore. My eyes got extremely
>sensitive to light. I had to wear sunglasses a lot. Too much glare during
>night driving also. My eyes felt dry, scratchy, and were blood shot all the
>time. My eyesight stabilized when I was wearing them, however...~Mari

I also read that contacts are better for your eyes in that they allow them more freedom for focusing and muscle moving (see above). I've always had conjunctivitis with my contacts, so I guess that's one of the drawbacks. For me, light sensitivity sometimes changed with the different brands, but it didn't lessen with glasses.

When I was very young (10 years?), I was prescribed hard lenses that were supposed to "reshape" my eye from elongated (myopic) back to normal. That never did work, I think it only hurt. Has anyone heard of that before? Any success?

dc :-)

I've been wearing plus lenses since I was a boy (fifty years ago), since it was my grandfather, Dr. Jacob Raphaelson (sometimes quoted in these posts), who (probably) invented the concept of using plus lenses for normal eyes. My near vision is the same as it always was - good - although I got near-sighted in law school and have remained so ever since.

In fact, my whole family (4 siblings and lots of cousins) wore plus lenses from an early age, and I haven't heard of any ill effects.

>OK, let's have that other discussion! Yes, I did think that the ciliary
>muscle is most relaxed when you see far.

Yes, just about every writer about the eye, whether conventional
optometrist/ophthalmologist or alternative thinker, writes about
the ciliary muscle the same way: relax to see far.

I'm not sure how the ciliary works. From my research, I'd say that
nobody else is sure either, even if they declare complete confidence.
The more I study the eye, the more amazed I am at how complex it is,
and how hard it is to study in a live human. In dead humans, the eye
decays very rapidly and so medical students sometimes study bulls'
eyes instead of human eyes. (There are detailed anatomy diagrams
of a bull's eye in a human dissection book!)

Some references and opinions on "work to see near OR far":

Atlas of Human Anatomy, Frank N. Netter, MD, 1989, Ciba-Geigy Corp, Summit, NJ:

Plate 83 shows "Anterior and Posterior Chambers of the Eye" and clearly shows "Meridional fibers" and "circular fibers" of the ciliary muscle, which is what controls the lens' focussing.

The ciliary muscle goes all the way from the very edge of the cornea (scleral spur) to the beginning of the optical retina (ora serrata), and all along that expanse, there are zonular fibers (ligaments) connecting the ciliary to the lens and a very large number of angles, connecting to the front and rear of the lens as well as the equator.

[Kip's interpretation: this muscle can affect the shape of the lens and not just how stretched out it is. Also, there may be changes in the cornea shape from ciliary pulling.]

R.V. Krstic, Human Microscopic Anatomy, 1991,
Springer-Verlag, p.512:

"The ciliary muscle is considered to be a single smooth muscle, consisting of interwoven muscle fibers which show some regional variation in the predominant fiber orientation."

[Kip's interpretation: possibility of astigmatic correction as well as further evidence of shape control to correct errors due to cornea.]

"The inner circular fibers ... are probably innervated by parasympathetic nerve endings. The meridional-radial fibers ... are situated closest to the sclera and seem to be innervated by the sympathetic nervous system."

[Kip's interpretation: Nerves act to focus close, and other nerves act to focus far. This is *NOT* simply a pull-or-relax design.]

"Accommodation is the dioptric focussing of the eye, achieved by changing the strength of the crystalline lens, i.e., its refractive power, to get sharp focussing of the visual image on the retina. At rest, the lens is held under tension by the meridional-radial smooth muscle fibers of the ciliary muscle, the whole ciliary body lies toward the back and exterior and the lens is pulled into a flattened shape. The eye is adapted to a far vision."

[Kip's interpretation: a muscle is WORKING, PULLING here to help you see far. This is *NOT* relaxed.]

"When the gaze is directed toward a closer object, the circular muscle fibers of the ciliary muscle contract, pulling the whole ciliary body forward and inward, and so decreasing the traction exerted by the zonular fibers on the lens; as a consequence, the lens becomes more convex in shape because of its elasticity, and the eye accommodates to near vision."

[Kip's hunch: looking near or far compresses one part and STRETCHES the other part, much as your upper arm works as you move your lower arm up and down. You need BOTH motions and both extremes to get both sides toned up.]

Another often-quoted reference that supports the dual-innervation idea is Toates, E.M. 1972 "Accommodation function of the human eye" *Physiological Reviews*, 52, 828-863. He gives a bunch of references to support it, too.

See also, on the web (not necessarily supporting the dual view):

<http://www.yorku.ca/research/vision/eye/ciliary.htm>

(says the choroid (layer between white sclera and retina) acts like a spring and is part of accommodation)

<http://mickey.lcsc.edu/~biology/MIKES/BI253/253out12.txt>

(talks about radial and circular fibers)

<http://retina.anatomy.upenn.edu/~lance/eye/lens.html>

(traditional view, but interesting)

http://www.prio.com/Diagnosing_Treating.html (talks about RPA

"resting point of accommodation" (what I usually call "Dark Focus" or TA=Tonic of Accommodation). RPA contradicts the idea of far=relaxed.)

http://www.prio.com/Research_TOC.html (lots more)

http://vsnet.net/vision_search/v_eye.html (traditional view, but good description of eye parts)

>> Normally, there is a connection or "loop" between your vergence (two eyes
>> pointing to a nearby object or pointed more parallel for a far object)
>> and your accommodation. However, when wearing pinhole glasses,
>> this "loop" is open (the loop being the two-way connection between
>> vergence and accommodation, each one reinforcing the other).

I sure don't know. Wearing an eye patch works around this problem, whether regular one-eye or Kaplan's "two-eyed patch". I think having reading glasses with prisms would make it more comfortable, at times. There have been researchers who have given people prisms too, but I don't recall one that had any success because of it. Alex gave a ref on one of these either on his web page or in Usenet long ago.

My hunch is "variety is the spice of life" so take vision breaks often and vary your accommodation full-range and your vergence full-range, and you'll feel better AND improve your vision. Stretch those muscles in addition to working them out.

Other refs for the nuts out there like me:

I would agree, depending upon what you mean by "be on guard." See below.

At 09:23 PM 11/20/96 -0500, MikeM727@aol.com wrote:

```
>Myopia is simply your eyes mechanism of adjusting to its average visual

>the average back to "normal". It works, no doubt about it.
```

This is pretty much what I used to believe. Then I discovered that I was apparently presbyopic. With a prescription that I could wear and just barely see 20/20 far, I couldn't read! (I had to take off my minus glasses to read.) I had lost my accommodative range, I would guess, from having worn plus lenses and keeping my eyes focussed at infinity so much. (Being over 40 years old didn't help of course.)

So, I started focussing near too, on purpose, including wearing my minus lenses at times. It didn't seem to hurt my progress, and in fact, sometimes it seemed to help. I now have a good accommodative range once again and can comfortably read with minus lenses on (though I usually don't!)

>Plus lenses cannot hurt your close vision. Even doctors who don't think plus
>lenses will help will tell you that it can't hurt. (The condition in later
>life that affects close vision is presbyopia, which is in no way caused by
>pluse lenses!)

Your eye's lens is made of living cells (some have no nuclei or organelles, though) that need nutrients and need to dispose of their wastes. There are no blood vessels, the usual way to supply nutrients and take away wastes, in the lens.

Accommodation massages the lens, and so the fluids on both sides can help here by supplying nutrients and taking out the garbage. The lens is mostly made of very long cells that are interlocked like jigsaw puzzle pieces. I believe that fluids can wiggle in here to supply nutrients and float away wastes.

If you wear plus lenses as an alternative to focussing near (presbyopia), then you won't accommodate as much and some of your lens' cells will die of hunger. This can cause cataracts (milky opaqueness of the lens made of dead cells and waste products.) (Lots of other things can cause cataracts, too. This is a controversial explanation.)

I would also suggest that dead cells, accumulated waste, and lack of lubricating fluids can cause your lens to become stiff. That is, lack of focussing leads to presbyopia. (I'm NOT saying it's the ONLY cause of presbyopia!)

I've heard of a number of presbyopic people who have lessened their presbyopia considerably by eye "pumping" where you focus near then far then near ... and sunning and other Bates-like techniques. One of them is a 65-year old woman who teaches Bates techniques in my town. She can easily read without glasses, as well as see far. She said she cured her hyperopia when she was 39 based upon Bates' techniques and has taught it ever since.

So: "plus lenses can contribute to presbyopia"
But: "plus lenses can be valuable in improving myopia if used in balance with some near focussing."

Thanks for all the energy stuff. I do think we are all supposed to cut down on reading and computer work and go outside and play. That is our addiction, and I think it relates to developing your left brain functions without doing the same with your right. I'm trying to go to books on tape. One book I was lent (I didn't read it, I skimmed it and looked at the pictures) says you can get prana from the earth, especially with your shoes off. And trees can give you their prana if you sit or stand near them. It is nice to be under a big green tree. I'm starting to believe there really might be fairies too, in a sense.

Julie

P.S. And maybe ultrasound was working along the same lines but the research got buried by the massive interest in corneal surgery.

"Investigators in Japan are using ultrasound as a treatment for myopia.

Treatments were usually 10 minutes every day for an initial group of treatments and then less frequently for a follow-up period of variable length. Small reductions in refractive error for low myopes have been reported. The mechanism underlying the effect is thought to be an increase of blood in the choroid or retinal vessels, or a decrease in tonus of the ciliary muscle. The efficacy of this treatment has not been tested in North America." Woo, George D., Wilson, M. Anne, Current Methods of Treating and Preventing Myopia, A Review, Optometry and Vision Science, Vol. 67, No. 9, p725.

Kip and other I_See'ers, got a question for ya.

I have noticed that using plus lenses while reading a book yields noticable improvement. However, using plus lenses while viewing a computer screen does not. Why would this be?

My roommate, who is much more myopic than me, noticed this first. Being more myopic and having more dramatic improvements than I, he could tell what works for him and what doesn't. When he read a lot on a computer, he didn't get any improvement, but when he read a book, he would. I resisted this testimony, because I saw no reason why it should be. Plus, I wanted to keep reading stuff on the computer as part of my therapy.

Now I have found that it's true for me too. I get no improvement whatsoever when on the computer. Now I have to wean myself away from the darn thing and start reading books!

Any explanations for this? Anybody have similar results?

Incidentally, I have an LCD screen (laptop) and he has a common CRT screen. Seems to be true for both types.

Mike

Mike,

i'm not sure if this is the exact reason or not but its probably pretty close... every dot that you see on the computer screen is actually just a projection of that dot from an electron gun onto the monitor screen. did you ever try to do any kind of focusing exercises through a mirror?? things just don't work right when light is reflected(or in this case, absorbed). i'm not sure if i stated this clearly or not... i'm sure that the radiation itself from the screen doesn't help either. for whatever reason, it seems that extensive computer time and good vision do not go together.....
jeff

oh by the way, i have heard that laptop screens aren't as harsh on the eyes as standard CRTs...

Thanks for clearing that up for me, Mike. (Hey, a pun!)
Clear as mud now. :-)

Since I'm myopic (can't see far) with astigmatism, this must mean my prescription is a minus something diopters plus some kind of cylinder measurement for the astigmatism. I'm in the process of finding an optometrist and will find out exactly what my prescription is and will also try to get a pair of "training glass". I don't wear contacts, so I don't know how I would wear plus lenses over my prescription lenses. I've stopped wearing my prescription glasses when I do close up work. I think my astigmatism makes things close up a bit fuzzy though.

Right now, I'm working on palming, sunning, swings, eye massage, eye chart exercises, and also I found an astigmatism chart at the library. That's enough to keep me busy, ey? ;)

Here's something interesting...I dug out all my old prescription glasses, thinking that perhaps I could use a pair for "training glasses". Ha ha. They all make me "woozie"--must be the astigmatism correction in them. I tried each pair on and looked at the astigmatism chart. Wow! Has the eye doctor been changing my astigmatism correction a lot! Every pair has a different correction and not one pair, including my current prescription,

corrects my astigmatism properly. Personally, I would like to totally eliminate the astigmatism correction from my eye glass prescription. I don't get headaches when I don't wear my glasses and I palm and massage my eyes when they feel stressed.

And for those inquiring minds who want to know, here's all I know about the astigmatism chart I have: As I mentioned, I found it at the library. The kit contained a cassette tape of eye exercises and some charts. It's called "Improve Your Eyesight Without Glasses", I don't know the author if there is one, it was produced in 1977 by Wolf Records, a division of Music Farm Inc., 615 E. Pike, Seattle, Washington 98122. Yes, I tried to order it and the local bookstores could not get it.

I've been making a lot of phone calls--ordering catalogs, books, getting eye doc. referrals, etc. I will let the group know what interesting things I find!

Thanks, Mike, for the info on pin hole glasses. I will check out the web sites you mentioned.

Personally, I don't see the benefit of judging things like contacts or plus
lenses good or bad, right or wrong. If those things work for you, great!
Well, that's my two cents worth, butting in on this conversation. :)

I don't know why that is either. But I have found that sitting far away, sometimes with the keyboard in my lap, seems to help. I just use my reduced correction.... It is actually more comfortable and I can read faster that way. I also make sure I look over at my wall calendar regularly, and out the window, too.

Sometimes I use the computer now without any correction, but at those times I must sit pretty close, and I do experience eyestrain sometimes :(

I find that working on the computer puts much much more strain on my eyes than reading. I think it may be because the screen is inherently blurry.

It is impossible to get a perfectly sharp image at any distance, no matter how good your vision, because the screen is composed of "fuzzy" dots.

If you consider the average screen these days is 800x600 pixels, compared to 600 dots per inch on an average laser-printer quality printout...

This means there are about as many dots on your screen as in about 1 square inch of laser-printed output.

Because the screen is blurry, perhaps this puts the eyes into a mode where they are trying to focus and never can completely get there.. thus causing strain?

Now what I'd love to see is an 8000x6000 LCD monitor. The images would be much sharper and I'll bet the monitor would produce much less

eyestrain.

I wonder how far off the technology is ...

Mary;

My guess is that reading a book is at a different working distance than looking at the computer screen (50-60 cm) and that the plus lenses are most often prescribed for the usual reading distance (40 cm). It is probably a good idea to get weaker plus lenses for computer use.

Mari, hello there!

There is an alternative technique called "Baby Mode" which may be just what you're looking for. It worked for me. I don't wear glasses at all now,

and haven't for years. You will find in this technique a strange resonance with the concepts contained in the paragraph you sited.

I have taken the liberty of attaching two files giving the gist of the method.

Have fun! If you sincerely desire to see clearly *again*, you can.

Regards,

Linda Wright

THE WRIGHT METHOD - AN ALTERNATIVE APPROACH TO CORRECTING MYOPIA

Briefly, I wore glasses for almost 20 years, and I have had some remarkable improvement by using the techniques I will describe below. Other programs exist, but I never had much success with them because they were too complex, involving too much discipline. The way I have finally found involves more a gentle change of lifestyle and seeing habits, and seems to get better results.

The Alternative Approach to Myopia is based on the principle that the body, given half a chance will heal itself. This is a fact. It applies to every part of the body, including the brain, as is now being discovered. Why should the eyes be any different?

When you begin to experience this for yourself, you will find that your initial improvement comes as very brief moments of sudden crystal clarity. These moments are called Clear Flashes, and if you have already experienced them then I am speaking to the converted!

Over time, these moments will become more and more frequent, and they will last for longer and longer periods. They will then begin to predominate, until you are seeing very well most of the time. You will still have situations when you can't see quite as well, such as at night, or in dim light, but even that will start to improve.

I am now in the night/dim light phase. I see perfectly out of doors, and now am beginning to see perfectly inside. This would have been impossible for me even a year ago, when I really didn't know *why* my vision was improving... just that it was. Now that I have gotten to the bottom of the Stress Model, I am polishing off the last deficiencies.

But five years ago, I couldn't read the lines in my own palm more than 6 inches away from my face. Today, I do everything without glasses, contacts or squinting. Tomorrow, my vision will be restored to what it was when I was a child, before it was so casually wrecked by slapping crutches on my face.

Here is my story;

When I was 9 years old, it was discovered that I needed glasses. Whether I actually did or not is a subject of some dispute with me, because as I

will explain, what I probably needed more was a break from the stress that had temporarily overwhelmed me and my little world.

It began as boredom in school, and was exasperated by a personality conflict with a teacher who probably disliked me almost as much as I did her. For some reason, she could not see that my rambunctious behaviour was my reaction to the things that were bothering me. My homelife was in a turmoil, another child (my sister) was on the way and my mother was ill. I wasn't coping well, and the class was going too slow for me. I read voraciously to stimulate my mind and escape, and even began reading in the dark under the covers by flashlight. I was a case of lifelong myopia in the making.

My teacher had been writing notes on the board for us to copy for the tenth day straight, and I had had enough. I put my pen down and refused to work. She noted this and became angry. I was headed for trouble and I knew it. When she confronted me, she offered me an out; "Can you see that?" she asked, pointing to her boardwork. I said, "no." She immediately wrote a note to my parents to tell them I needed glasses. By accepting that excuse, I was spared a serious punishment, or so I believed!

Having painted myself into a corner, when I was taken to the eye doctor by my folks, I was anxious to fail my test, because then I would not get into trouble. Now I have to say that failing the eye test was not hard, because I did have a bit of a problem seeing because I was genuinely stressed. But at the time I knew exactly what was wrong, and that I didn't really need glasses even though I did have some slight blurring. I just needed someone to realise that the class was going too slow for me and that I wasn't happy in school.

I got my glasses, and my father insisted that I wear them constantly. I kept trying to go without them (as many mildly myopic children in the same situation so often do). But it was no good. I got in trouble every time my parents caught me without them on, and within two weeks I had a *real* problem. My eyes were wrecked.

Now I see how I contributed to my own problem, but only after having considered the events of that time over almost 20 long years. At age 9, I didn't have the wisdom or the strength of resolve to stand up for myself and say what was really troubling me. The emotional stress I was going through was real however. In relative terms, an adult in the same situation might have turned to drink or drugs. But enough about that.

I never lost the conviction that wearing glasses was wrong. But I was trapped, and for the rest of my childhood I had to pay for my one moment of weakness. I won't bore you with the details of how bad it is to grow up wearing glasses, because surely you already know what it's like.

But the damage was more than just cosmetic or emotional. At age 16 (after only 7 years of wearing glasses) I received a blow to the head which resulted in a torn retina and surgery. Myopia was doing me damage far greater than what I could have imagined. The surgery was successful, but the risk was always there of further injury. I had floaters and white spot flashes, both classic evidences of myopic atrophy of the eye. I got scared.

By age 29 though, I was more or less reconciled to the idea that there was no solution, and that this was my "cross" in life. The news that surgery might fix my nearsightedness excited me only briefly, since I had already had one operation and didn't look forward to another. I always longed for a cure though. I never gave up hope.

I tried contacts for a while, because over the years, my perscription was getting stronger and stronger. Unfortunately I don't remember what it was, but my eye doctors looked grim whenever I asked them if things were getting better. I suppose I really didn't want to know. In talking to ophthamologists since, we've worked out that it was probably about -10 to -12 diopters at its worst. Very bad.

Then, shortly before my 30th birthday, I had a lucky accident. I broke my glasses, for the umpteenth time, but this time, it was over a holiday weekend, and there was nothing I could do. My contacts were not in any state to be used as a substitute. I was in trouble, or so I thought at the time.

I was virtually blind without my glasses. I couldn't see clearly more than a few inches in front of my face. How was I going to make it through the weekend? I was afraid of getting hit by a car, or falling down stairs.

Wandering around the streets, trying to keep from getting hurt, I ended up playing safe by going into a fast food restaraunt. I was feeling very sorry for myself. Munching on my burger, I happened to glance across the street. I read a sign for a sale, then went back to staring at my food. All of a sudden, it hit me; I shouldn't have been able to read that!

I looked back up at the sign, but once again it was just a big orange blur. Too late though, I had caught my eyes in the act of focusing!

I was shocked! There had been a brief improvement, and contrary to the orthodoxy that I had been taught, this shouldn't have happened!

I had discovered quite by accident that my vision was not set in cement, but that it *varied* slightly from hour to hour. A slight variation, to be sure, from extremely disfunctional to very definitely disfunctional! But it had changed.

The fact that it *changed* was the point. Until that time, I didn't believe it could. Right then I swore off glasses for life, and decided I wouldn't replace the pair I had broken. I went home and I threw out my old contacts and everything that reminded me that I had once worn glasses, save one photograph, which I kept for other reasons. Since that day, I have never put another pair of glasses on my face, and never will.

It wasn't easy going cold turkey. I believed that my vision would improve naturally, out of the influence of my glasses, which I had suspected since childhood had been the cause of my problems all along.

In the time that followed, I realised that my eyesight wasn't going to improve in a week or two. I honestly didn't know why it should take so long, but I tried to find out. It was a slow process of discovery, discarding one wrong idea after another, until I finally had the whole picture of what was holding

up the show. Eventually I discovered some basic principles that I will share with you;

- 1) Ordinary Myopia is caused by stress, and stress is the main factor inhibiting its improvement.

Not only emotional stress, but environmental stress. Bad seeing habits like squinting, reading in bad light etc. Wearing glasses of the wrong perscription. This and almost any number of like things can contribute. All of these things, as well as childhood emotional trauma played a part in my myopia, beginning at about age 9. And even after I stopped wearing glasses, in my ignorance I was continuing to generate stress by being anxious to see clearly again. I gave myself a very hard time! This was the wrong thing to do, since it inhibited my progress.

- 2) If you get rid of the stress, you stand a better chance of improvement. It's largely what the *eyes* consider to be stressful that is the important thing.

Do you suffer from eyestrain? If you are familiar with eyestrain (and I've never met a myope who wasn't) then you know what stress means to the eye. The mind is willing to go on, but the eyes are not, and so we push our vision past the point where it is able to function normally. If we were lifting weights with our arms, our wills would not be strong enough to push us past the limits of our muscles, but because the eyes are small, they are easily overcome.

The tension of eyestrain is only the grossest form of stress on the eye. There is also what I call "ambient stress" which only myopes seem to have, and that is the stress and strain of the eyes having to stay fixed so that they can see through glasses. This is a technical fact, that when you wear glasses, your eyes must *work* to keep your eyes in place.

Now here's an ill-kept secret; if you've been wearing glasses every waking hour for 20 years, then your eyes have actually atrophied in place, just as if you had worn a cast on your leg for the same amount of time. If you wear a cast on your leg for 3 or four weeks, then when it comes out of the cast, the muscles will have withered away to virtually nothing, and you won't be able to bend your leg without extensive therapy. Why should your eyes be any different? What do you imagine would happen if you wore a cast on your leg for 20 years?? You'd be surprised to find a leg left at all!

So your eyes, having been kept rigid for years by wearing glasses will need to be gently worked back into shape so that they can function normally again. This will take time. However, if you just launch into a program of exercise for your eyes, you may only be inadvertently straining them again. The thing that the eyes need to do is learn to relax, and the chief lesson for the eyes to learn is that *the glasses aren't there any more*!

I discovered that if you could *defuse* this remembered stress and tension, instilled by long years of wearing glasses, you could begin to make rapid progress. How do you do that? That is the question, one that took me a long time to answer. I will give you the answer for free, so you can get

started straight away, but first I have to explain a few things;

You can't just tell the eyes to relax. Nor can you simply relax them like any other part of the body. The eyes, when they are perfectly relaxed don't focus at all! This fact adds to the problem of learning to deal with visual stress so as to see better. It poses a paradox, the existence of which explains why all the relaxation techniques in the world will not take your visual improvement more than a couple of diopters in the right direction at best. There is an element of dynamism involved that is missing in the idea of relaxation which is added to the technique I am about to describe.

BABY MODE

It took me a long time to discover *the actual active ingredient* in my improvement. I thought that it was simply a matter of spending time out of doors, looking around, not squinting etc. But there was an exact principle that it took me 5 years to define. Based on this principle, and in conjunction with my Stress Model, I now have worked out a technique which anyone can do, which doesn't involve exercise, and which is the single most effective thing I have ever tried.

I call it Baby Mode, though it is based not so much on how babies see, but on how young children up to the age of 5 look at the world.

It's quite simple. It involves the practice of looking at the world as a child does. That is all. How do you do that? By understanding how a child looks at the world!

What follows is very important and should be considered carefully and understood fully. A child's visual practices are quite distinct from a myopic adult's.

A child;

- Next to never fixates on any single object.
- Their eyes are naturally relaxed, all the time, not tense as myopic eyes tend to get.
- They blink in liquid motion, not forceably.
- They look at things because *the objects of their attention are inherently interesting*, ie, the world is (still) a fascinating place to them.
- They look to learn (a myopic adult is trying to learn to look!)
- Their attention span flits around a lot. They see many more things in the same amount of time. Myopic adults miss seeing many things, even when they are wearing their glasses!
- They look at the whole of any scene, and see it in greater 3D depth.
- They look at things to learn about them (adults already familiar with the world look at things to IDENTIFY them, thus they never really see the thing once they get the ID. Focusing is curtailed.)
- They don't squint, except of course in strong light, and even then, only rarely.
- They don't read in the dark, or in dim light. It puts them to sleep.
- They yawn a lot, and clear their vision by looking away whenever they get tired.
- They never get eye fatigue because they never force themselves beyond the point where fatigue begins to set in.
- They see clearly without even being aware that they are doing so. They never give this autonomic function so much as a moment's thought.

Observe children closely, and you may pick up a few more pointers. Or better yet, *remember how you used to do it!*

The main idea here, and this is the key to practicing the technique is to remember how *you* used to look at the world, and put your vision back in its original state. You *used* to do it like this, if you were ever non-myopic. Then you stopped. You need to go back to doing it that way. That's the essence.

Whenever I can't see as sharply as I ought, I remind myself to go back to Baby Mode, and my vision clears immediately.

All the other complex ideas concerning how the eye actually works are interesting, as theories, but if they don't yield a practical therapy, then they are simply academic excursions. I have a model of myopia, called the Stress Model. The Stress Model yielded the Baby Mode technique. It works well, and is theoretically *sound*. But you can practice Baby Mode without really knowing how or why it works.

The only trick to Baby Mode is learning how to put your eyes into that state, and then remember to keep them that way. You'll see results. Of course, it will take time, but I've tried everything of which I am aware, and this is the safest route to steady rapid progress that I have so far discovered.

MORE ON BABY MODE

* How to Get Into Baby Mode the First Time

First, by remembering its characteristics from your past, then by putting your eyes *back into their past mode of operation*. When I first started doing it, I used to remember my childhood, and the innocent way in which I looked at the world as if it were brand new and made just for me.

Here are two ways to do it;

- The easy way; Cast your mind back to when you were a child and could see clearly. Put yourself back in time and *feel* how it was for you. Have no fear, the flesh remembers. Recall the sheer delight you felt in looking at all of the bright colours, the play of the light on things, etc. See the world in the round, afresh. Discard the tension around your eyes and set aside your adult cares and concerns.

- If you can't remember what it was like to see as a child, then do it like an actor would, as if you had been asked to give a very convincing performance. BE a child for one brief moment, and set your mind in the frame that a child would have. It's not about personality, or being giggly. It's about the way you see the world.

* How can you tell if you're in Baby Mode?

You will know immediately, because when you are in Baby Mode, you will notice an improvement instantly. It may only be slight, but the fact that it has changed in a positive direction is the indicator. Note how above I said that when I remind myself to get back into Baby Mode, my vision clears up immediately... that's the clinical indicator.

* What about Clear Flashes? How does Baby Mode relate to these?

Baby Mode may or may not induce a Clear Flash every time you go into it, but overall, you will see more Clear Flashes the more you stay in Baby Mode. A Clear Flash is an inadvertent jump into perfect Baby Mode. Baby Mode is a conscious thing you practice till it becomes the unconscious norm. Clear Flashes begin to come more frequently, and last longer.

When I began practicing Baby Mode (the discovery of which was inevitable once I worked out the Stress Model) I started seeing things again that I saw every day as if it was the first time that I had ever observed them. I was startled! Colours became brighter, things got "rounder" and fuller, and lo and behold, sharper! Anything that attracted my attention got it, only I found I wasn't staring at things so intently as I would have before.

But then I would suddenly realise that I was seeing clearly and my *focus* shifted from what my eyes were seeing to what was going on with my eyes. I fell out of Baby Mode and the clouds came over again. No problem... I knew I was onto a good thing. I just slipped back in again, without sweating it, and the same effect occurred again and again.

* Are there any other characteristics of "Baby" vision I should know about? Yes. Children do not constantly check their vision to see if they are seeing clearly.

This is something that myopes tend to do obsessively. It is typical in fact for a child to have a vision problem for weeks before it is picked up, and comes as something of a surprise to them. This is because they give seeing *no attention at all*. It is just something they do automatically.

Its like the situation where most healthy people are not aware of their heart beating, except when it is brought to their attention. A heart patient on the other hand is aware of little else. One can say that even with 20/20 vision, a recovered myope is not cured until seeing no longer absorbs any of their conscious attention. I am almost at that stage after practising Baby Mode. When I've reached it, I'll probably write down everything I know about correcting myopia naturally and then disappear off the scene, back into the normal world!

UPDATE

If you keep it in mind that young children with perfect vision are constantly in Baby Mode, and myopic adults are next to never in Baby Mode, you'll realise there is quite a gap to be bridged.

Once you know what it feels like, there is minimal effort or disciplined involved. It is now habit and routine for me. At first it required some conscious thought, but now it only takes a moment of remembrance to set things right again.

Don't think though that when you've done it once or twice, that's it. It's not a magic wand. The rule is that if you think you are doing it, but you aren't experiencing an instant improvement, then you are not doing it! Don't then become obsessed with it again. Just remember to do it right whenever you realise you can't see clearly, and the habit will soon become engrained. That is my last piece of advice.

Soon I will no longer be involved in this field, for the simple reason that myopia will not be an issue for me, and it is better that I stop putting my attention on it. This is one of the principles of Baby Mode, and I know of no other approach which has as its aim the complete elimination of the problem.

You will soon get to this point as well when you are "in the groove" with Baby Mode. Before you leave the scene though, you should pass on this information to others who may be helped by it.

I envisage a time when glasses are no longer prescribed for myopia. Instead, when myopia is detected in both children and adults, a trained person will gently lead the affected person into the (restored) practice of Baby Mode, by getting them to do again what they once were doing, and stop doing what it was that caused the problem in the first place. That is my dream.

But I have no plans of starting a one-woman movement to effect this. This method will live or die on the basis of its results and ease of application. Consequently, if this works for you, if you understand it well and apply it consistently so that you get results, you have then an obligation to reproduce it in others who are in need. One becomes two, two become four, and so on until it becomes common knowledge, and no one would ever *think* to give a child glasses for myopia or operate on corneas again.

BABY MODE CLARIFIED

There has been a fair bit of discussion on how to get started with Baby Mode, in particular, concerning the problem of how to remember how you once looked at the world.

I would not want to see the demonstrable benefits of using this technique limited to only those who by some good fortune are able to remember their childhood clearly, thereby excluding those who do not or cannot.

Therefore, I have to correct any mis-impression there might be surrounding the principles of Baby Mode and the supposed need to "remember" one's childhood in order to do it.

Very simply put; It is not necessary to remember one's childhood in order to initiate Baby Mode. The actual active ingredient in Baby Mode is the restoration of the original mode of seeing. Remembering your childhood is but one way of helping in this regard. Memory is a fickle friend, and even those who remember their childhood perfectly do not as a consequence experience Baby Mode. That is because memory remembering your childhood is not the trick.

I don't want this to seem at all cryptic. Please recall my original post introducing Baby Mode. I wrote;

> I call it Baby Mode, though it is based not so much on how babies see, but on how
> young children up to the age of 5 look at the world.

> It's quite simple. It involves the practice of looking at the world as a child
> does. That is all. How do you do that? By understanding how a child looks at
> the world!

Simply by *understanding well* how a child looks at the world, you can accomplish
Baby Mode. That is the core principle. Only later on in my post did I
introduce the idea of "remembering" how one used to do it. Remembering is a
shortcut to understanding, if you can accomplish it. What I am saying is that
all that is necessary is adequate understanding and an act of will.
It still can be done, and rather easily, even by those who remember nothing of
their early years.

I went on to say,

> What follows is very important and should be considered carefully and understood
> fully. A child's visual practices are quite distinct from a myopic adult's.

This is the basis of what must be well understood. In detail, in order to give
people a headstart, I enumerated the key points...

> A child;

>

> - Next to never fixates on any single object.
> - Their eyes are naturally relaxed, all the time, not tense as myopic eyes
> tend to get.
> - They blink in liquid motion, not forceably.
> - They look at things because *the objects of their attention are inherently
> interesting*, ie, the world is (still) a fascinating place to them.
> - They look to learn (a myopic adult is trying to learn to look!)
> - Their attention span flits around a lot. They see many more things in the same
> amount of time. Myopic adults miss seeing many things, even when they are
> wearing their glasses!
> - They look at the whole of any scene, and see it in greater 3D depth.
> - They look at things to learn about them (adults already familiar with the
> world look at things to IDENTIFY them, thus they never really see the thing once
> they get the ID. Focusing is curtailed.)
> - They don't squint, except of course in strong light, and even then, only rarely.
> - They don't read in the dark, or in dim light. It puts them to sleep.
> - They yawn a lot, and clear their vision by looking away whenever they get tired.
> - They never get eye fatigue because they never force themselves beyond the point
> where fatigue begins to set in.
> - They see clearly without even being aware that they are doing so. They never
give
> this autonomic function so much as a moment's thought.

>

> Observe children closely, and you may pick up a few more pointers.

You see? Anyone can come to understand the essential principles involved, by reason alone. There is nothing mysterious or complex about it.

Once you understand it, all you need to do is do it, that is to say, all at once, put your visual behaviour back into that mode. Not by thinking about a list of things to do, but by seeing the world as a child does, as you once did. In short, be a child again in the way you see.

Bad vision is a **habit** for most of us. The old bad habits need to be replaced with new good habits. How do you do that? That is the secret of Baby Mode. That is what Baby Mode essentially accomplishes, far more quickly, painlessly and easily than most other methods I've seen. But the key is understanding, not memory.

The practice of Baby Mode is analogous to realising that you have the habit of frowning all the time; When you first realise this, and that you look far more attractive when you smile, you must for a time remind yourself to start smiling again.

Initially it will be difficult, because it won't seem **right** and it won't look genuine. So to get it right, you have to smile sincerely from within, by thinking of something worth smiling about.

Now you can **remember** something worth smiling about, or you can **contrive** something worth smiling about. But only when you've got it right in your mind will it work on your face. You will fail many times, and slide back into frowning for weeks yet. But

you will get it right eventually, and then smiling will be effortless and natural. That by the way is an almost perfect analogy of how Baby Mode actually works.

Incidentally, just as you can't force a sincere smile, so you can't force Baby Mode. Force and effort are antithetical to both smiling and seeing. Only three inches separate the muscles that perform both functions... isn't that interesting!

As well, and some of you have already realised this, Baby Mode is NOT just another relaxation technique. Relaxation will only take you part of the way, a very short distance in fact. Relaxation may prevent your eyes from getting worse, and you may get early improvement from it, but it will not take you the rest of the way. Before I discovered Baby Mode, I was one of those people who'd gone 90% of the way to 20/20 and spent at least two years trying to fix the last 10%. I needed Baby Mode to finish what I had started in throwing away my glasses.

Why is Baby Mode different to the general relaxation techniques we have all been trying to follow with mixed results? Because relaxation is passive, and Baby Mode is active. A **totally** relaxed eye will not be able to focus. The eyes are active organs, constantly in action. They **have** to move in order to work. That's why relaxation is not the entire answer.

SUMMARY

This, then is the full context in which I wrote the line

> Or better yet, **remember how you used to do it!**

Of course, if you can remember, then great. But I must say clearly now, that remembering how you saw as a child *by itself* will accomplish absolutely nothing. I know, because I spent many many hours doing exactly that. Only when I realised that I could put my visual behaviour back into its originally perfect mode of functioning by a conscious act of will did I then directly experience change under conscious control. That one realisation, *that I could do it* was the key. It worked the instant I got it right.

>From that initial success, I persisted, making the rule,

> Whenever I can't see as sharply as I ought, I remind myself to go back to Baby Mode,

> and my vision clears immediately.

There you have it. Rememberance is nothing without the conscious action of the will to restore the vision to the original mode of operation. That you can do by reason, aided by memory, but not by memory without reason.

Finally, in this vein I wrote,

> All the other complex ideas concerning how the eye actually works are interesting, as

> theories, but if they don't yield a practical therapy, then they are simply academic

> excursions.

I would not like Baby Mode to become an academic exercise or a magical mystery tour. It's not a navel-watching thing. It's something that anyone can do. As soon as you've done it once, you'll never forget it or forget how to do it. You will see an instant difference in your vision the minute you've done it. It then becomes a simple matter of remembering to do it again, every time you become aware that your vision is not 100%. After a few weeks or so, as with correcting a permanent frown, it will become second nature, and your advancement will be steady and predictable.

Of course, if you were never confused about how to do this, and you've already done it for the first time, then there is no problem. But if not, or if you are struggling a little bit, this should hopefully help you get on track.

Nothing in all the world would please me more than to know that you have won your well-deserved freedom with this technique.

Linda, Thank you for the "Baby Mode" info. Mark Jones had generously sent me the info previously. So group, anyone else out there currently using this method? How's it working for you?

I may be over simplifying the method, but, to me, the gist of it is talking about experiencing a paradigm shift in the way we see our world. I remember this type of thing happened to me when I was taking a drawing class. Even things like the dull pavement became fascinating to me, because I was really seeing it for the first time and noticing all the details of it. (Check out the book, "Drawing On The Right Side of The Brain", by Betty Edwards for more on this.)

I printed out the list of how a child sees the world and will post it where I will see it every day as a reminder.

~Mari

This bit interested me greatly.

"as a myope i can converge but I can't diverge. I find it easier to do my divergence exercises with the pluses on."

For some reason I had thought that although looking into the distance required accommodation and divergence, that it was the accommodation problems that caused myopia. Does myopia always come with divergence problems too? Can it be one without the other (eg just divergence and no accommodation problems?) Can you test for yourself which it is?

Can anyone point me to divergence exercises? (Looking into the distance presumably counts. Does the buttons/knots on a string exercise?)

Caroline

I also experience some eyestrain using the pluses. I think they're meant only for reading, to relax your eyes so you can see far away naturally again. The convergence/divergence explanation makes perfect sense: as a myope i can converge but I can't diverge. I find it easier to do my divergence exercises with the pluses on.

Do ya think?? This is something I've been considering.. not actually quitting my job, but taking a long vacation, not using the computer at all, not reading... just relaxing and playing ... with no visual correction.

I am trying to go as much as possible without vision correction and I've started marking the days on my calendar with a big N.C. (meaning No Correction) when I can manage to go the whole day without correction.

I've gone 4 days straight lately. I've had a few noteworthy clear flashes.

Today I was able to read a license plate at 45 feet. Since the letters on the plate are about 3 inches tall I gather this is about 20/50 unaided vision ...

The license plate was not crystal clear 100% of the time, but

I could clear it at will.

I find that working on the computer puts much much more strain on my eyes than reading. I think it may be because the screen is inherently blurry.

It is impossible to get a perfectly sharp image at any distance, no matter how good your vision, because the screen is composed of "fuzzy" dots.

If you consider the average screen these days is 800x600 pixels, compared to 600 dots per inch on an average laser-printer quality printout...

This means there are about as many dots on your screen as in about 1 square inch of laser-printed output.

Because the screen is blurry, perhaps this puts the eyes into a mode where they are trying to focus and never can completely get there.. thus causing strain?

Art Blake -> art@blakesys.com

For me, using a DOS based, blue screen background program (such as Word

Perfect) is MUCH easier on my eyes than trying to look at thin black letters on a glowing white background in Windows.

Tim

I think I can partially answer this one. My husband is even more of a myope than I, yet he immediately was able to "see" the hidden 3-D pictures in those Stereogram picture books. I, however, could not at first. Eventually I was able to see them in "reverse" by crossing my eyes and gradually letting them uncross.... After about a week of trying for a few minutes twice a day, I was able to get the "right" picture by looking beyond the top of the book, then letting my eyes drift down.....

So it seems some folks with myopia have little trouble with divergence (like my dear husband Steve). Others might (like me). I have since become skilled at seeing those pictures - all it took was learning what it felt like. Hope that helps... maybe others will share their experience.

Mary

Does anyone else have any info on those stereograms?

I saw some in a catalog that were supposed to be for myopia. But I had read that the way you actually see the stereograms is to converge your eyes. But yet when someone was trying to teach me to see them, they said to relax & see "beyond" beyond the picture, much like what you do when you use the accommotrac.

So now I'm confused. Is it possible that they make some stereograms to work with convergence and some with divergence? What actually makes them work?

Should I go out & invest in some stereogram posters to work on my divergence?

Thanks 8-)

So far, the exercises I have been given include watching people on the
street as they pass by and looking at the space "between" people. I assume
they're divergence exercises...I'll ask the therapist tomorrow.

In a message dated 96-11-26 13:44:41 EST, aeulenbe@indiana.edu writes:

> Actually, reading glasses with prisms have been made for that very
> reason. The idea goes back at least as far as the 1930s.

I don't know, Rehm says no glasses can eliminate all three: accommodation, convergence, and stereopsis. I suppose it's the latter that cannot be eliminated by plus lenses even with prisms. There's always going to be a significant difference between the angle each eye sees an object at a "close" distance. I don't know if it really **needs** to be eliminated, though. Rehm claims it does. I suppose it has to do with the instinctive connection between the three. When you sense stereopsis, the eyes are used to accommodating and converging.

> Note that if you put a patch over one eye when you read, this will also
> cause your eyes to diverge, probably.

I don't know about that either. The visual system has been trained all its life that when you look at a close object, the eyes need to accommodate and converge. I still think that, even with one eye patched, the other eye will converge when looking at a close object. After all, that's what it's "supposed" to do, right?

Patching has been mentioned a lot on this list, in this and other contexts.

What is the supposed benefit of patching? What about the fact that patching, lid-suturing (sp?) or otherwise occluding the eye CAUSES myopia in experimental animal models?

Hi Everyone!

Hope you all had a great Turkey weekend!

Has anyone with high myopia (I guess I mean anything over -6.00) had any positive results going cold turkey without ANY correction?

I also took advantage of the long weekend (five days) to try a cold turkey experiment. Starting Wednesday, I used nothing but pinholes for correction while at home, and when I had to go out in public (Thursday & Friday) I wore -5.00 glasses (I started out with a glasses prescription somewhere over -9.00, but since starting accommotrac, my vision has improved just over 0.5D).

I'm beginning to think that this experiment was a big "No-No" for me! I don't notice ANY improvement (I realize 5 days isn't much, but I can't do this when I have to work), and actually not wearing anything (the pinholes don't really correct my vision, they only prevent bumping into walls) and not being able to see just made me frustrated! I feel as though I just wasted the time, when I could've been out doing something more productive!

>I am looking forward to going without my glasses for a couple of
>weeks straight this holiday season, when I don't have to work.

>Art Blake -> art@blakesys.com

An interesting finding relating emotions to vision....

While working with the accommotrac the other day, I discovered that I could alter the feedback sound based on what I was thinking. If I thought about something sad, the sound became lower/slower (showing that my eyes were'n't relaxing), but if I thought about something happy, the sound immediately became more positive.

There are other things I can do to "manipulate" the results from the machine, suggesting that simply "relaxing" is not enough to stop the over-accommodation.

Has anyone else tried anything like this with any results?

Dawn 8-)

I have had some good results.. The worst I ever was was -6.50 D in both eyes. Going without glasses at -6.5 is pretty rough. I'm now at -4.5 and it is not quite so bad. I can imagine how hard it would be at -9.0!

It's important to try not to expect an improvement.. you have to learn to just take what your eyes are giving you at the moment, without any thought of improvement .. you can't force it to happen, because part of the problem is that you are trying! You have to just "be" not do.

This is kind of a big point ... you have to get to the point where you can not wear your glasses, and not let it bother you at all. Just accept whatever images your eyes give you, as they are. If you feel frustrated or stressed, you will not accomplish anything, and may even cause more damage. You have to sort of "love" your blur. With such a high prescription, you might be better off to start with a reduced prescription if it is just too frustrating.

Another thing you could do is go to a good movie you have already seen, and watch it through without your glasses, making sure to blink often and stay relaxed.

I tried this once (though on a movie I *hadn't* seen before) and found that I actually enjoyed the movie and could tell what was going on.. even more so, I could see better when I came out of the movie! Bear in mind I'm at -4.5 and sat in the front row. I think a true movie screen is much easier on your eyes than a television .. because the image is much clearer and originates from a clearer, more pure light (as opposed to a scanning electron gun in a TV picture tube.)

Do not worry that the images you see are a big blur, just let your eyes go and enjoy the soft images you get..

Also, don't worry about the sharpness so much, but maybe try to notice the colors more... notice your peripheral vision more.. Don't notice what you CAN'T see, notice what you CAN see! And when you have your glasses off, colors should

be much brighter, and your peripheral field of vision should be much more opened up. Take this opportunity to enjoy the wider field of vision and better color perception, and don't worry about the blurriness.

I can actually see better in many respects without my glasses than with.

For example, if I am about 100 yards away from a stop light, I can easily see if it is red or green without my glasses, and the red, green and yellow colors are unmistakable. But with my glasses on (reduced prescription), I cannot easily and instantaneously tell the color differentiation even though the image is a little sharper.

Excellent books to read:

"Take off your glasses and See" by Jacob Liberman
"The Power Behind your eyes" by Robert-Michael Kaplan

Now while reading, don't wear your glasses either. What I tend to do is hold the material the maximum distance away that I can still read it, without putting extra strain on my eyes. Even if you have to hold the material quite close, it is much less of a strain on your eyes than reading with the glasses on ..

> >I am looking forward to going without my glasses for a couple of

BTW, I didn't get to go as long without my glasses over the holiday weekend, as I wanted to because I was looking for a new apartment. Maybe over Christmas!

Cheers

When I started on the accomotrac, the therapist told me to think of something stressful. When I did, the sound instantly got lower pitched. Then she said stop thinking that. The sound returned to its higher pitched tone. Then she said think of something happy, this correspondingly raised the tone.. so yeah, I got the same effect..

Another therapist had a good sense of humour, and when he could make me laugh on the machine, my numbers rose as well!

So .. yeah, the machine pretty much refelcts your level of happiness or sadness, which reflects your level of stress, and therefore blood flow to the eyes ... I wonder if a mood ring would work too :)

Here's a web site especially for parents. Visit the site of Parents Active for Vision Education (PAVE). There is info on vision therapy and vision related learning disorders. They have a recommended reading list and a way to contact the national office and local chapters.

I noticed a MAJOR improvement in my vision, especially the astigmatic part, this last week. I had a few days to myself (husband and daughters on family pilgrimage - I stayed home to watch new puppies). During that time I did pretty much what I wanted (hit three big bookstores, two eclectic hole-in-the-walls)! I also had enough psychic quiet to come to the decision that I will pursue a healing career (homeopathy, mainly). That is when I got the clear flashes - more like a veil lifted.

I have always had an interest in the healing arts. I formerly read the Merck Manual for entertainment - mesmerizing stuff. But the treatments didn't match my philosophy. I have finally found a modality that does, and I seem to have a knack for it. Even better, my mate is very encouraging - he thought I should do this last year :) My daughters have always thought I could work miracles, so I have much support. Seems the only one lacking was ME! As I am typing this I realized how right this all is, how happy it makes me.... and I look around the room and see everything clearly, with my reduced perscription. Think I'll go trade that last box of disposable lenses for another reduced perscription!

Part of vision improvement for me was to get comfortable with not "doing something constructive" every once in a while! I used to read compulsively (the newspaper, cereal boxes, deodorant labels), watch TV too much and use the computer the rest of the time. I was physically uncomfortable during times when I wasn't using my eyes for close work.

I took up juggling for those times when I had to wait (I usually read a book). Not only is it fun, good exercise for body and eyes, but it also allowed me to be more social. People are at ease talking to me, and I am comfortable talking with them (this doesn't happen with a book). Now I sometimes just sit and have conversations, without the juggling 8)

Another side effect is that I have come to value what I feel/think/believe more than what I read! I am trusting MY perceptions, instead of relying on the written word to tell me what is out there. I also find it easier to try on new ideas and question old ones. I still check out a lot of library books, but now I read the part I am interested in and skip the parts that rub me the wrong way. It is more fun, and I get more of what I value accomplished 8D)

Acupressure"s Potent Points, a guide to self-care for common ailments by
Michael Reed Gach
ISBN 0-553-34970-8
Bantam new age Books

Its still in print I saw it recently at Barnes and Noble in the US.
I highly reccommend it I use it all the time. It has a section on eyestrain.

best of luck
alexandra

I reported this phenomenon in my book Seeing Without Glasses. While guiding my clients to see more clearly on the eye chart, I would say things to them to see if their perceptions would change. I was amazed at how simple words could alter their visual acuity by sometimes as much as 3 lines. I continue to use this method with other vision practices. Just this weekend, a post surgical farsighted person was able to turn on his right eye perception while using a fusion type activity when he said; Be Open!. This natural biofeedback use of our eyes never ceases to amaze me.

Enjoy,

Thanks for the reference!

I have that book, too. I've been doing those exercises for almost a year now. I'm pretty much addicted. I also learned a similar one: you make circles around your eyes (up the insides of your nose, across the eyebrows, down the sides of the eyes, and across the top of the cheekbones back to your nose) with your fingers, making the circles about an inch wider every five or so circles. When you get to the outer limits of your face, you can massage your head & shoulders. This practice is supposed to get the same points as the Chinese exercises, plus a few extras.

Good luck!

dc 8-)

I really enjoy the facial massage exercises and neck and shoulder ones as well. Janet Goodrich's also has some good ones too. I also read about this one exercise where you put hands over your ears and apply pressure gently and make circles. This really is relaxing for me.

I am aware that you are in the -9.0 area. My latest prescription was left eye -7.5 and right -6.75 and I am only 14 years old. I only wear my -5.5 glasses when I am at school. The rest of the time I go cold turkey. I used to always "check" my vision constantly. I know its hard especially since

you can't see farther than 4 inches away, and that is pretty inconvenient when reading or doing close work. You always have the paper very close to your face. What I have learned though is to not look at the world but rather let the world look at you. Like many others mentioned on this list, the key is not put any effort into it.

The reason I like this group is it provides support, encouragement and new ideas, people can express what they feel, which is helpful.

A very important factor in getting clearer vision is having someone to lean on in those difficult times. It can get tough, and sometimes even feel impossible throughout Vision Therapy.

Good luck on your journey to clearer vision,

-Peter

Dawn, I can relate to what you said about feeling frustrated. I think I first got started with this vision therapy stuff about a month ago. It's easier for me to go without my glasses now. At first, I would notice I got irritated because I couldn't see clearly, especially when I was looking for something. Gradually, I've "let go" of wearing my glasses more and more and I'm surprised at how much I *can* see. (I have my glasses hanging on a chain around my neck, so I can slip them on anytime I need to see clearly.) I still get frustrated when it's high stress situations like when I'm really busy at work. If I notice myself straining a lot, I put on my glasses.

After about a month of this, I think I may be seeing the eye chart a little better and the lines on the astigmatism chart are more balanced, which means my astigmatism has improved. Also, it's easier to read without my glasses. But that's about it for improvements. Is this the normal rate of improvement? I realize that being new to this stuff, I probably haven't been doing the actual eye exercises very much. I've mostly concentrated on eye massage, palming, swinging, some chart work. I'm just wondering how much time per day is everyone spending on this? What is your regular daily routine for vision therapy? What exercises do you do and how do you fit them into your daily activities? Any suggestions for me? Thanks, Mari

As I see it, there are two kinds of "daily activities" for vision improvement.

One is changes in your visual habits. That is, you do the things you always did, but you use your eyes differently. For example, taking vision breaks from reading or TV or computer to focus far on something and see it as detailed as you can. Another example might be using idle time such as at a traffic light or in an elevator or whatever to practice focussing near and far ("pumping"), stretching your outside eye muscles by looking far left, right, up, down, diagonals, or tracing distant objects' edges. These things you do for the rest of your life. These don't take any "time" from your day.

The second is active work that does take time. This would be studying an eye chart, sunning, palming, trying to read as far away from your eyes as possible (using plus lenses on top of or instead of regular glasses if necessary), more intensive pumping or other exercises.

I certainly don't know the ideal mix of time spent on all these. In "Improve your Vision without Glasses or Contact Lenses" by Beresford, Muris, Allen, and Young, the authors call the second activity "Booster Techniques" and suggest 1/2 hour a day for

30 days. You can then stop them (but continue with the new visual habits) and resume them some other time for another boost in vision. The authors suggest that your improvement will be in bursts with stable times between the bursts.

You can be creative in finding ways to embed vision therapy components in your regular life. An important part of that, of course, is maintaining normal relationships with others, who might think you're behaving a bit strangely. If you are stuck on always looking completely normal, you might miss out on some good ideas. Think of yourself as being on the leading edge of a revolution in how people see. Part of that involves educating yourself and others so you and they can accept your new behaviors.

Hi there,

I've been reading the list for a while although have only contributed once or twice as I have not been as dilligent in my quest to elliminate my myopia as I would have liked. anyway i thought I'd tell you what happened the last time I visited my optician.

My prescription at the time I had the check-up was L:-1.75 R:-1.25 and I found when wearing my contact lenses (which I only wear a couple of evenings a week when going out) that my left eye had virtually no blur and my right eye was slightly blurry. The optician tested my eyes and determined that I needed a stronger prescription of L:-2.25 R:-1.75. After he had tested my eyes I asked him what my new prescription was and he seemed reluctant to even tell me, saying that its not important - (he used the analogy that its just like a shoe size!). I explained that I was concerned about my vision deteriorating further if I was given stronger lenses and was told that myopia is purely genetic and the effect of the natural 'growth' of the eyes. I mentioned that I had been investigating the possibility of vision improvement and was told that it was all 'absolute rubbish'.

I don't know why but at the time I believed him - I took the view that he must know what he's talking about if he's been trained in ophthalmology. So I got the stronger glasses and wore them that evening. I found however that my eyes felt very uncomfortable in the new glasses - I must mention that I usually get around without my glasses, using them only for lectures, tv, driving and such activities. I was convinced that the glasses were too strong so I went back to the opticians asking if I could revert to my old prescription. I was told this was not possible and my only course of action was to have another checkup. During this checkup I explained that I don't usually wear glasses for the majority of the day and I really need them as a boost to my vision, not necessarily giving me absolutely crystal clear

vision when I wear them. He 'strongly advised' me to simply wear the new prescription until I got used to them. (This alarmed me - it didn't seem right that my eyes should adjust to the glasses - surely it should be the other way around!). I explained that my contact lenses were fine, in the left eye and that they probably needed a very small boost in the right, and asked if I could revert to my old prescription with that adjustment. He argued that if I changed the prescription in my right eye (from -1.25 to -1.5) then I should also change the left to match (-1.75 to -2.00) which seemed ludicrous to me as the vision in the left eye was fine anyway and I was actually bringing the strength of the two lenses nearer to each other which seems more natural. Well I had completely lost faith in the optician by now and asked outright for a prescription of L:-1.75 and R:-1.5 which he very reluctantly prescribed, making a long note on his pad and calling the idea 'daft'. Since wearing these new glasses I have found that they are perfect for my needs, only giving a minute blur at long distances, also any difference in clarity between the two eyes (with the lenses) is inperceptible.

I thought that I would tell you this story in the hope that anyone who has a similar experience might be wary of what any optician might recommend, against the gut feeling of the 'patient'. I'd love to hear from anyone with a similar experience.

Regards,

Rob (21)

Hi Mari!

I started reading about vision therapy about a year ago & started doing
massages (Lieberman ones, every morning & nite) & easy stuff. When I went
to my eye dr, I begged him to lower my contact lens prescription, the best I
could do was -0.5D, which wasn't much lower because it turned out my contact
lens prescription was higher than it should have been. To get it lower, I
complained that it hurt to switch between my backup glasses & my contacts.

Now I'm doing the accommotrac through a very educated doctor and an
extremely sensitive vision therapist (yes, it's expensive :- (). Within
two weeks, I had very clear vision with my old "reduced" contacts. Now I do
palming with my eye pillow (thanks for the idea, guys!), plus lenses over my
contacts and over nothing (only for a few minutes at a time, one eye at a
time--I use the pluses to look at a chart & sway back & forth to see if I
can make it clearer), and divergence exercises (previously described). Last
week's attempt to go cold turkey was a failure, I'm back to only -5.00's
(glasses) at home and last week received a pair of -7D(L) -6(D) lenses for

work (it was hard at first!). I still can't read without my glasses, but I use plus lenses for both computer (-1,00D) and reading (-2.00) over my contacts. They seem to produce the most immediate results.

The most effective thing ever was changing how I use the computer & read. Also just generally moving my eyes around (Goodrich: using your nose as a pencil & outlining things--this is especially fun on the NYC subway, now I fit right in!). When I get tense, I move my eyes in various patterns to each far corner & along the sides of my vision. Normally, my eyes progressed -1D every year to year & half. I know for certain they haven't gotten any worse.

As for actual time per day, it depends, because I can't really do much at work (I work 10-12 hours per day, and most of the time I work with bank CEOs & stuff, so I have to be 100% focused on them), but I try to be constantly aware of how I'm using my eyes. At home, it's 10 min here, 15 min there, maybe a total of an hour a day, more if I'm not working, but it's not really concentrated effort, except that it's hard to see with the reduced prescription (it's almost half). When I tried to go cold turkey, there wasn't much else I could do!

Hope this helps!

Dawn :-)

> My eyes have improved a quarter of a diopter by patching alone (from -0.5
> and 01.0 to -0.25 and -0.75).

Really? You didn't do **anything** else? Not even wearing your minus glasses less?

> As I understand it (very imperfectly but here goes), the benefits are:
> 1. The patched eye is given a rest.

Is it really? If something, like a patch is stuck in front of an eye, isn't it being forced to accommodate?

> 2. The unpatched eye is given a chance to work alone and if weaker than the
> patched eye, given an incentive to improve itself instead of relying on the
> better eye.

Well, couldn't you do that with plus lenses alone? If you read at the blur-point, the radial fibers of the ciliary muscle promote "active relaxation", or actually working away from accommodation. But if you read at the far-point, you ciliary muscle will simply be relaxed. If you had eyes that had different degrees of myopia, you could just hold the reading material so the "weaker" eye is at the blur-point (working) and the other eye is at the far-point (relaxing).

> 3. My behavioural optometrist mentioned something about improving
> flexibility. Not sure if this is rate of accommodation or what.

I dunno either.

> 4. Improved peripheral vision since the other other eye is 'missing' -
which
> (but I'm not sure how) is supposed to reduce myopia.

I dunno that either.

> 5. Eliminates convergence/divergence problems from seeing and allows the
> eyes to practice focussing alone.

I'm not convinced that it does eliminate convergence. I think when the eye looks at something close, it converges, as it has been trained all it's life to do. It's a factor of distance, not whether or not both eyes are being used. (Unless a person had monocular vision all his/her life, then they eye would have never been trained to converge in the first place.)

> >What about the fact that
> >patching, lid-suturing (sp?) or otherwise occluding the eye CAUSES myopia
> in
> >experimental animal models?
> Tell us more!!

There are hundreds of studies where myopia has been experimentally induced in animal models by, one war or another, restricting it's visual environment. This has been done by lid-suture, restrictive hoods, translucent occlusions, or negative lenses.

That's why I thought patching might be bad. However, the key might be the absence of light during patching. If you had something, anything, restricting your vision, that would cause excessive accommodation, which is bad. However, if your eye was deprived of all light, the ciliary muscle wouldn't even try to focus, and would just go into it's most relaxed position. (I think Kip calls it the TA, Tonic of Accommodation.)

So, I guess, as long as you keep all the light out when patching, it's OK. I still think you'd get more "active" improvement by reading at the blur-point. It makes your eyes *work* at focusing far, and that's the whole goal!

Mike

If I were you I would get a new doctor! There are plenty of eye doctors who have heard of natural vision improvement and are perfectly willing to help us in our quest for improved vision!

It's a simple matter of making a few phone calls, and asking a few questions.

You can tell pretty quickly if the doctor is receptive or not.

It is a fact that these techniques work. I (and many others on the list) can personally vouch for this with my 2 D of improvement!

Good Luck.

-

Recently, Dr. Kaplan wrote:

>>Just this weekend, a post surgical farsighted person was able to turn on his right eye perception while using a fusion type activity when he said; Be Open!. This natural biofeedback use of our eyes never ceases to amaze me.<<

I find this very interesting as my quest involves "turning on" my left eye.

Me: 36 year-old wife and Mommy of five. Strabismus as a baby (about 8 months age), first crossing, then after 2 operations, divergence (left eye looks up and out).

Very little central vision in left eye. I keep telling myself that my eye is perfectly fine (which is what ophthalmologists and optometrists have told me) but that it is one small area of my brain that needs to "turn on".

I am amazingly functional (if I don't count not seeing stereograms as important...), but, of course, I worry, what if anything ever happened to that right eye. No more driving (God help my kids), no more reading or, dare I say it...COMPUTER!!!!!! Ugh!

So, every night I scan the room with my left eye (edging objects) and relaxing and hoping that it will register in my brain.

Somehow, the dim room allows me to perceive the edges of objects (the doorway, windows) as dim shadows because there is less distraction peripherally(?). The more contrast there is (bright lights), the harder it is to see the edges. It is just a dark spot.

You might imagine, I would really like to find a person just like me to

compare notes. I really have to work to explain what it is I am perceiving. So, if anyone has central blindness in one eye (or both, God forbid!), let me know!

To the group: Everytime I think I need to unsubscribe myself because the amount of mail generated is pretty high, you all are so interesting I just can't do it!

Thanks! ;-) <squinting eye???

The challenge in post surgical situations like yours is the residual scar tissue, trauma from the surgery and the brain and mind still being wired for a turned eye condition. The metaphor I see in your case is the need, perhaps, to diverge more in your life. I wonder what that means? Good vision and if I can be of any more help please let me know.

Hello fellow memebbers.....

I've noticed the following phenomena: during the WEEKENDS my vision actually improves dramatically and during weekedays my vision sort of sucks. It's goodish in the AM, but after 10 hrs of CRT it's out the window....

I do not use a computer during weekends and I barely watch TV.

I have also noticed that most of my fellow computer users (especially on the unix side) tend to be near sighted....

Any ideas anyone?

I can understand why computer use should be restricted. It's hard to sit very far away from the screen - but what is wrong with a television if you sit the other side of the room? Is there something more than the focusing distance involved here?

I think the problem might staring, not blinking as much and maybe holding your breath. Television provides a perfect environment for those bad habits, but it isn't alone.

Have fun,

-Peter

When I first heard about vision therapy I called around to optician shops to find out if I could get 20/40 lenses. No one had heard of vision therapy. A few had heard of pin hole glasses. I ended up making an appointment with my own eye Dr. who's secretary said "Oh, that's the old school." Well, I had a conference that day that started at 8:30 and my Dr appointment was at nine.

So I cancelled the appt. and wrote my own prescription down by 1/2 diopter on each side. I'm an M.D. but I actually just whited out an old Rx from 1989 instead of rewriting my own. I did the therapy on my own and got another lower prescription. After I could tell from the wall chart in my office that I had improved by one diopter on each side I made an appointment with a behavioral optometrist. She confirmed this improvement. At this point I was kind of mad that no M.D. had ever advised me to try a vision therapy program.

I had dinner with an ophthalmologist friend and went over my experience with him. I think he thought I was a loon from outer space and I thought he was a brainwashed zombie. He said I must be squinting. I may not be a specialist but I can tell whether I am squinting or not. He also said the optometrist was biased in her measurements. He seemed not to realize that I as the patient was not a lab animal and would know whether I was seeing better or not. He's the one who was biases. I'm tired of them all.

Julie

Subject: Food Irradiation?

Food & Water Action Alert: Hormel Foods Considers Irradiation Technology

Hormel Foods recently attended a pro-irradiation symposium in Austin, Texas. Concerned that Hormel's attendance might indicate that the company supported irradiation, Food & Water asked Hormel whether or not the corporation intended to pursue the technology. But Hormel refused to reveal the corporation's policy regarding food irradiation.

Since that time, Hormel has said that, although it does not currently expose its products to radiation, it might consider using irradiation if consumers would accept the technology and if the company decided that irradiation would make its products "safer."

Hormel is one of the largest food processors in the United States. If Hormel condones food irradiation and decides to use the technology, the doors will be open for a wide range of food processors, from fruits and vegetables to meat and poultry, to "follow the leader" and expose their foods to irradiation as well. Now is the time for

everyone concerned about food irradiation to take action.

-- Call Hormel at 1-800-533-2000, extension 5269.

-- Let their corporate representative know that you are aware of the dangers associated with food irradiation.

-- Tell them that you will only support companies that give assurance that they will not knowingly expose their products to radiation.

-- Ask them for a promise that Hormel Foods will not expose their customers to the unnecessary risks of food irradiation.

-- Tell the corporate representative that you will not be satisfied until you see an official Hormel policy rejecting irradiation. Tell them you know that Hormel Foods, as a leader in the food industry, has the ability to ensure that the company will not use irradiation in the future.

-- If Hormel responds to your call with unusual comments that you think we should know about, call us at 1-800-EAT-SAFE and let us know. We'll pass the information on to future callers.

The Problems with Food Irradiation

-- Food irradiation exposes food to the equivalent of 30 million chest X-rays.

-- Irradiation creates new chemicals in foods called radiolytic products. Some of these products are known cancer-causing substances (like benzene in irradiated beef). Others are unique to the irradiation process and no one knows what effects these have on human health.

-- Irradiation destroys essential vitamins and nutrients that are naturally present in food. No studies have been done to show that a long-term diet of irradiated foods is safe. Safer, well-tested alternatives to irradiation exist.

-- Irradiation plants pose environmental threats to workers and surrounding communities. The transportation of nuclear materials to irradiation facilities also poses severe public health risks.

For information about Food & Water, or for hard copies of this Action

Alert, call us at 1-800-EAT-SAFE.

Is This Why FDA Commissioner David Kessler Quit?

NUTRASWEET RECALL DEMAND BASED ON KEY RESEARCH INFORMATION THAT IS
RECENTLY REVEALED BY A FREEDOM OF INFORMATION ACT REQUEST !!!

ATTENTION: Assignment Editors and Producers for
IMMEDIATE RELEASE

Contact: Betty Martini
Mission Possible
(770) 242-2599

In 1981, aspartame, the artificial sweetener also known as NutraSweet, was approved by the FDA. Of the 112 papers submitted to FDA by Searle Pharmaceuticals (in the FDA Index of Master file No.134 for Aspartame), 15 studies were designated "PIVOTAL". One of those studies was E-32; a "52 Week Oral Toxicity Infant Monkey Study (SC-18862)."

The researcher and author of the monkey study notes a significantly high

level of phenylalaine in samples of blood serum. Aspartame is made up of three components. Phenylalaine which makes up 50% of the formula, aspartic acid is 40% and methanol is 10%. The study concludes that:

"The convulsions in the monkeys are correlated with and can be attributed to high serum phenylalaine levels"

It is often difficult to review every page of every study so submitted to the FDA. On page 3,197 of the aspartame application, this study reveals:

"All animals in the medium and high dosage groups exhibited seizure activity. Seizures were observed for the first time following 218 days of treatment....The seizures were of grand mal type....."

The study correlates the seizures with the high amount of phenylalaine ingested by the monkeys. The author of the study noted:

"Following the termination of treatment, medium and high dose monkeys were kept under observation for 3 months on powdered Similac. No further convulsions were detected during this period."

Dr. Robert Moser, NutraSweet spokesman, declared no scientific evidence was ever found to implicate aspartame as the cause of seizures?! Here was the PROOF that should have resulted in an ASPARTAME BAN! HOW WAS IT MISSED?

As a group of citizens around the world we demand that ASPARTAME (NutraSweet, Equal, Spoonful, etc.) be immediately and forever banned. It is a chemical poison when ingested causing seizures, depression, brain damage, memory loss, headaches, blindness, tumors, birth defects, infertility, etc. Mission Possible and the partial list of doctors and organizations that are attached support this recall:

IS THIS WHY FDA COMMISSIONER DAVID KESSLER QUIT? NUTRASWEET RECALL DEMAND!

Two weeks before Kessler resigned Dr. Robert Moser, NutraSweet spokesman, declared no scientific evidence was ever found to implicate aspartame as the cause of seizures. An Atlanta activist group, Mission Possible, announced Tuesday FDA had conclusive evidence all along, but chose to ignore it, and Kessler approved NutraSweet as a general sweetener for all foods in June. But now it appears that the S.S. NutraSweet has hit the iceberg and First Mate David Kessler has just jumped overboard. FDA designated 15 of the studies upon which NutraSweet approval was granted as "Pivotal Studies". One study proved Dr. Moser wrong.

"A 52 WEEK ORAL TOXICITY INFANT MONKEY STUDY"
(SC-18862)

Seven monkeys were divided into 3 dosage groups.

"52 Weeks" was actually 204 to 364 days.

Data was "lost" on the monkey which died

One monkey, P53, had "congenital physical deficiencies" resulting in "poor growth due to inappetance."

Data on this one was also "lost".

"limitations in adequately skilled laboratory personnel contributed to our decision to eliminate the requirement of a control group in this study." says the report.

What happened to the little monkeys?

"All animals in the medium and high dosage groups exhibited seizure activity. The seizures were of the grand mal type. One monkey, M38, died after 300 days. The cause of death was not determined."

The report continues: "Following the termination of treatment, medium and high dose monkeys were kept under observation for three months on powdered Similac. No further convulsions were detected." The study makes this conclusion: "The convulsions in the monkeys are correlated with and can be attributed to high serum phenylalanine levels." This Pivotal Study proved aspartame triggers gran mal seizures in monkeys. The seizures stopped when aspartame was discontinued. They took the "No-Aspartame Test and got well. You're the monkey now, as this poison is fed to earth's human population.

The late Dr. Adrian Gross, FDA Toxicologist, summed up separate test, on rats, and listed 14 blunders, including:

Unreported tumors. Incompleted examinations.
Missing batch records. Hiding deaths.
Destroying rats before they could be completely analyzed.
Mixing foods so rats could avoid the aspartame.
Resurrecting dead rats on paper.

Dr. Jacqueline Verrett, FDA toxicologist testified in 1987 in U.S. Senate hearing that the tests were a disaster, should have been thrown out; and data in the study was worthless. She said: "(aspartame) was too unstable to be used in hot preparations, hot liquids and also diet drinks."

The soft drink companies knew in advance aspartame degrades into toxic components, and protested to Congress in 1983. Five pages of their objections were printed in the Senate Congressional Record on May 7, 1985:

"OBJECTIONS OF THE NATIONAL SOFT DRINK ASSOCIATION TO A FINAL RULE PERMITTING THE USE OF ASPARTAME IN CARBONATED BEVERAGES"

"Objection One: Searle has not demonstrated that aspartame and its degradation products are safe for use in soft drinks
... Aspartame is inherently, markedly and uniquely unstable"

However, the greatest evidence is in the bodies of thousands of aspartame victims, well known to the FDA. In 1995 FDA listed 10,000 complaints with 92 symptoms including seizures, blindness and death. 75% of all complaints to the agency on additives are on aspartame. This report is available only through Freedom of Information as FDA conceals anti-aspartame data.

FDA Commissioner Arthur Hayes, Jr. who approved NutraSweet, overruled the Public Board of Inquiry established to investigate the safety of the product. Hayes later resigned to work for NutraSweet's (Searle) public relations firm while he was under investigation for accepting gratuities.

The fraudulent tests that ended up approving NutraSweet were so corrupt that Federal prosecution was initiated against Searle. But the government prosecutors switched sides to hire on with the defense attorneys and the case died when the statute of limitations expired. NutraSweet was bought by Monsanto in 1985.

The foregoing depressing events are but the scum on top of the cesspool of scandal surrounding aspartame, a recognized neurotoxin that now finds a place on every restaurant table and in millions of homes worldwide. It must end. We must proclaim it from the housetops, one to another until the bell of freedom from the scourge of aspartame rings clear in all lands.

We, citizens of the world, to defend the lives and health of all mankind, hereby demand that ASPARTAME (NutraSweet, Equal, Spoonful, etc.) be immediately and forever banned. It is a chemical poison. It causes seizures, depression, brain damage, , memory loss, headaches, blindness, tumors, birth defects, infertility and abortions, is escalating Alzheimers and causes DEATH! Murder by chemistry must fall!

A partial list of doctors and organizations supporting the recall of aspartame (NutraSweet) is attached.

To get more information on aspartame, email betty@pd.org as follows:
Subject: sendme help The subject line must be typed exactly like the above line. Betty Martini 1. Take the 60-day No-Aspartame test Mission Possible and send us your case history. PO Box 28098 2. Tell your doctor and your friends. Atlanta GA 30358 3. Return Aspar-Poisoned foods to the store. USA (NutraSweet(tm), Equal(tm), Spoonful(tm), etc)

We are dedicated to the proposition that we will not be satisfied until death and disability are no longer considered an acceptable cost of business.

Someone on the health newsgroup just posted something about algae (e. g., Cell-Tech) having been found to be bad for the eyes.

Since there has been a recent discussion here about blue-green algae (Cell-Tech, Synergy, et cetera), has anyone here heard anything about this?

Thank you very much for any information anyone can provide.

Best regards,
Virginia

A friend of mine has a relative from China staying with her. The woman has a degenerative eye condition that has been stabilized, and her ophthamologist told her to take 15000 units of vitamin A with palmatate (not beta carotene) each day.

Is anyone familiar with this? Can anyone tell me why it would be preferable to beta carotene (and under what circumstances it would be)?

Thank you very much.

Best regards,
Virginia

Hello I_seers,

I had an interesting awareness experience. First I always thought that if your myopic that whatever you focus on is blurry and that your peripheral vision would be equally blurry or more blurry. For me, I just became aware that i can see fairly well but also a lot better with my peripheral vision than what i focus on.

How come if my "eye is too long" that my peripheral isn't worse than what i focus on ? If the eyeball is elongated, how come the peripheral vision and what i focus on are not blurred equally from what they were before? Could this be because minus lenses encourage you to look through the center of your lenses, resulting in staring and using only one part of my retina while barely using the outer part of the retina.

Am I right here, or am I not "seeing" something? :)

Have Fun,

-Peter

Gee whiz, what else could it *possibly* be??

>I may not be a specialist
>but I can tell whether I am squinting or not.

You mean you *don't* have to go to school for an additional two years for
that sort of information? Based on the prevailing attitude (of eye doctors
in my experience) I couldn't POSSIBLY have a clue as to ANYTHING having to
do with my eyes.

>He also said the optometrist
>was biased in her measurements.

Jeez. He knows her? He was there? This sort of stuff makes me want to shriek.

>He seemed not to realize that I as the
>patient was not a lab animal and would know whether I was seeing better or
>not. He's the one who was biased. I'm tired of them all.

>Julie

Darn it. You should've been an eye doctor. I'd fly across the country every year for a checkup if that's where you were. I've just been to three boneheaded eye guys (one was an eye gal, actually) in as many years; they were all recommended to me and they all had the attitude you describe. I couldn't ask a question more complex than "where's the restroom?" without getting strange looks. The attitude was that if I wanted to understand the Meaning of Lenses, I had to go to school for that -- it wasn't in the doctor's job description to explain anything to me. (They're just my eyes, folks, it's okay!)

I decided about 10 years ago that mom, grandma and the eye doctor were completely wrong, as I had noticed that my eyes went downhill more slowly when I only wore my glasses for distance reading and driving. I tried to explain to one of the doctors that I wanted her to write an undercorrected prescription and she didn't even understand what I was saying. I think it was so far from her experience that she couldn't even *hear* me.

So how likely is an eye doctor to return your phone call and answer your questions? Other than my pediatrician (who is now my son's pediatrician) I have never met a doctor who thought he had time for that sort of thing. Should I just start calling around? Send letters? I don't want to take any more recommendations if the darn doctor hasn't got time to do much besides get the cash and insult any form of therapy besides surgery.

I'm not happy to hear that other folks have similar experiences and reactions, but it's reassuring in a way to know that at least I'm not the *only* one who's got wacky ideas.

:)

Hello I_seers,

I was going through some of what is posted at the I_see page, and read something i not to sure about.

Alex wrote that minus lenses bring the picture closer to you and the higher the degree of myopia the closer the picture is brought in. Am I right then in saying, that if you have -8.00 lenses on and are focusing at something at twenty feet away, that the picture is brought in within your 12.5cm range. So you may see twenty feet away, but are truly only focusing within that 12.5 cm range.

If this is true, which i am not sure and am asking, that could explain why myopes become progessive, they are limited to what distance they can focus at, causing strain in the cillary muscle.

Comments, Question or Answers appreciated,

Have fun,

-Peter

```

Here's a trick you can use to get a reduced prescription from an eye doctor (OD) without having to discuss things that the OD "can't hear." (I've also noticed that selective deafness.)

"Ok, this minus prescription does seem to allow me to read that far-away chart just fine. However, I've sometimes had trouble reading close. Perhaps I'm getting old or getting early presbyopia, but when I put on plus one reading glasses on top of my regular glasses, I can read much easier, and I'm more comfortable in front of the computer, too.

"Would it be possible to get a separate prescription for reading glasses for me? I think one diopter less minus would be just right."

(Eye docs can hear "diopter" and "presbyopia" without thinking you're a vision improvement freak.)

At that point, the OD might get out the tiny type reading chart and put it about 14 inches in front of you and experiment

with "how does this feel?" If you say "oh, that's much better" at the right time, you'll be all set.

Whether plus one diopters is right for you or not, only you can say, but it would be wise for you to have some familiarity with which amount of plus to add to your regular minus prescription BEFORE you go in to see the OD. (Hang around the reading glasses section of the drug store for a while, trying on different pairs of reading glasses over your regular glasses or contacts.)

Bates would suggest that you might need improvement in "Central Fixation" to improve your vision. I sure don't know. You should probably check out Bates' suggestions to see if they work in your case.

Another perspective:

A child's eye is approximately spherical like an adult's eye is. However, the lens/cornea focussing component must be much more powerful in order to bring distant images into focus on the closer retina. As the eye grows, the power of the lens/cornea reduces to keep things still in focus.

A myope with a lengthened eye has a LONGER eye, but not necessarily a LARGER eye. That is, the shape is distorted. This is not the same as simply having "too much plus" in the front of your eye.

Most people assume that if -3 Diopters of minus lenses correct your vision, that means that your eye is simply +3 D too plus. This is nice and simple, but it ignores the distortion in shape.

The sides of your retina may be closer to the lens than the

center of your retina, and so images are more in focus there. Unfortunately, the sensors in your retina (rods and cones) are not as dense on the sides, so even if the image is clearly projected on the retina, you won't see fine details.

In your other note, you asked:

>Am I

>right then in saying, that if you have -8.00 lenses on and are focusing at
>something at twenty feet away, that the picture is brought in within your
>12.5cm range. So you may see twenty feet away, but are truly only focusing
>within that 12.5 cm range.

Yes, the -8 D lens makes a "virtual image" of the distant object appear at 12.5 cm. You're living your whole life inside a 12.5cm box, never looking further away. The orthodox perspective is that there is a hard solid stop to your focussing ability at your far point, and so there's no need to ever try to focus beyond that. If you put on +1 D reading glasses on top of your -8 D glasses, you've made your box grow to 14.3 cm instead. Ahh!! Some breathing room.

```

A dioter is $1 / (\text{the focal length in meters})$

so $-8D = -1 / (1/8 \text{ meter focal length})$

or the focal length is $-1/8 \text{ m}$ or -12.5 cm

is that how you got 12.5 cm ?

what is the significance of the lense being plus or minus in calculating the amount of compression of space that is occuring? If someone is far sighted, does that mean they are expanding too much as opposed to compressing like a myope would ?

Also, if a -8D myope is viewing everything at a 12.5 cm range, why do the images still *look like* they are just as far away as they really are when wearing correction (as opposed to appearing to be at 12.5 cm.)

hmm... I just did a quick check (I'm not wearing any correction) of how far away from the screen I am reading. At 17cm I have perfect clarity.

At 21 cm I can still read the text, but can't really read it any farther away (its very small text on a 17" monitor at 1280 x 1024 pixels...)

this corresponds to -5.88D for full correction and -4.76D for reduced correction... These are very close to my actual measurements (I wear -4.5 correction.)

I wonder if this is a fairly valid way to measure your correction ... ?

Any doctors care to comment?

PS. I tried looking at 12.5 cm and it feels like I am way too close (even though it is only about 5cm closer!)

Hi. After a year of trying to find alternatives to bifocals, "visualizing" optimal sight, which often works very well for me, I obtained glasses. As a person who strongly believes in alternate methods, I've been disappointed by the paucity of alternative treatments for presbyopia.

My sister-in-law, a few years younger than I, embarked on a course of vitamins-C, B complex, lecithin and perhaps some others.

Do you know of this approach, or of any references for this and other approaches?

Thanks
jlartin@epix.net

```
> If this is true, which i am not sure and am asking, that could
> explain why myopes become progressive, they are limited to what distance
> they can focus at, causing strain in the cillary muscle.
```

BINGO! That's exactly what happens. The minus lenses force even more accommodation which exacerbates the ciliary muscle spasm. The ciliary muscle constantly pulling on the outer coats of the eye causes the elongation known as axial length myopia.

It is interesting that studies on one species of primates shows that when accommodation is eliminated, the elongation of the eye (progression of myopia) ceases. However, on another species of primate, the constant close focusing still causes elongation even if accommodation is eliminated. This suggests that axial lengthening is controlled by higher level neural inputs from the retina. Perhaps in humans it's a combination of the two. Either way, excessive close focusing, which is aggravated by minus lenses, causes progressive myopia.

Mike

-

First let me report a small success! My prescription is -5.75 in both eyes plus some astigmatism. I also have an exotropia that I am battling at the same time. In fact my main goal is maintain what stereo vision I gained when I was doing supervised VT.

Anyway, I tried going without any glasses at all to see if 1) I could and 2) see if the eye exercises I read about make any more sense that way. I'm pleased to report that I was able to go at least 20 minutes before I "had to" put my lenses on. It isn't easy, but I was pleased with the small progress I had made. Back to the questions:

I'm confused about the concept of the blur zone. When I don't wear lenses, it is clear enough where the blur zone begins (very close to my face). With my lenses, my blur zone appears not to exist. The problem I have is should I do eye exercises with or without my lenses? If with, then I'm not sure about where the near point and far point should be. If I do them without lenses, The near point is clear, but the far point either needs to be relatively close (so I can make it out without straining) or I need to strain and squint, neither of which seem right. any help out there?

Stereo-grams: I have placed them on my cubicle wall, above and beyond my computer. I have two of them, one I have never been able to do at all (thats my goal, to see the planet). The other one I can do at normal reading distances, but when its at the wall (3 Ft away) I can't really seem to hold it. Almost, but not quite. The question is: should I be able to do it at any distance?

Plus lenses: Since I have bifocals, do I still need plus lenses (for stress reduction) or can I merely use the bottom part of my lenses.

Thanks in advance.

Barry

I understand what your saying, but how come people who are severly myopic, lets say over -15.00 aren't constantly cross-eyed because their focus point is 6 cm away? What do you think the "breathing room" should be in terms of mesurment? or would you just knock off a diopter?

Have fun,

-Peter

Do glasses perhaps allow for focusing using a different level of accommodation, but with the original level of divergence???? If so, you wouldn't go cross eyed.

Caroline

Does anyone have any information about using light in vision therapy? Many of the vision therapy books available talk about the benefits of full-spectrum light (sunlight) and doing exercises with it. I saw a mention of the use of "full-spectrum" or "blue" lightbulbs that could substitute.

Does anyone know how effective these "full-spectrum" lightbulbs are?

What makes them different from regular lightbulbs?

Where can you buy "full-spectrum" lightbulbs?

As always, thanks for your help!

Have a great day!

Dawn 8-)

 - *Date:* Wed, 11 Dec 1996 09:31:43 EST
-

My dilemma is: I use Ortho-K lenses to correct my myopia, but would like to use plus lenses to permanently correct vision (a la Vision Freedom). I have had very favorable short term results using plus lenses, but then my OrthoK contacts feel weird, and I feel an eye strain while wearing them.

Using OrthoK contacts (which maintain my eye shape) conflicts with using plus lenses (which change the shape of my eyes). If I chuck my very expensive Ortho-K lenses, would my eyes revert to their original state (20/400 R, 20/175 L) ?

I saw a letter on the net from a Commander Gray, who was in a similar situation about a year ago.
My goal is 20/20, with no lenses.

Any suggestions would be much appreciated.

Sincerely,
Tim

Your eye's optics have "axial chromatic aberration", which is comes from your lens and cornea focussing blues and reds differently. (Blues focus closer to the lens, reds further away, so myopes could see reds easier than blues.)

Depending upon where you focus on a white spot, your retina would have a blue dot surrounded by a red circle or a red dot with a blue circle. (I'm simplifying and ignoring greens, yellows, etc. in white light.) Some researchers think this is how your eye knows whether to go "in or out" to clear up a blur. Some also think that if you're not exposed to full-spectrum light your focussing won't develop correctly.

The human body isn't so simple, though, to have one mechanism for something as important as this, so even when they put special lenses in front of the eye to cancel out the chromatic aberration, the eye can still focus. That doesn't mean it's not used, just that it's not the ONLY way you know where to focus.

>Does anyone know how effective these "full-spectrum" lightbulbs are?

Here's the spectra for "cool white fluorescent" and "full-spectrum fluorescent" bulbs (I don't know whose bulbs or how truthful this is):

<http://www.cybergate.com/~lovelea/11.htm>

You can see on that spectrum that sunlight has a very smooth spectrum, but that the "full spectrum" bulb has sharp spikes at certain colors. Who knows how your eye deals with this.

As for how effective they are, like most vision-related studies, you'll find them on both sides -- valuable and useless. My feeling is that you should get a good dose of natural sunlight every day possible. Getting a VARIETY of light, brightness, distance, nutrition, etc. is more important than trying to get a lot of the "right" thing.

>What makes them different from regular lightbulbs?

Every kind of bulb would have a different shape spectral curve. The curve is the amount of light emitted in each color region. Your eye is lousy at seeing the real spectrum, so you need more tools. You should ask to see a spectrum chart before spending big bucks on a bulb, and if they don't have one, don't buy it. Anyone selling a "good" full spectrum light would have measured the spectrum and would be proud to show how superior their bulb is compared to others. It's possible, though I haven't seen it, to have a collection of colors on paper that would tell you if you have full-spectrum light by looking at the colors. That is, you could make a paper-based spectrum detector. You'd need a lot of special dyes, though, and not just mix three "primary" pigments.

Incidentally, your lens absorbs a lot of blue and UV (ultraviolet, the normally invisible color just beyond blue-indigo-violet) light. However, your retina can still see into the UV. So people who have their lenses removed can actually see more colors (deeper into violet, I suppose) than you can. (Not that I've experienced this...)

Greetings, Visioneers!

I just got my Inter-Library Loan copy of Lisette Scholl's *_Visionetics: The Holistic Way to Better Eyesight_* (New York: Doubleday, 1978), ISBN 0-385-13279-4. It looks quite good.

There is an address at the beginning where one may write the author to request a brochure describing a series of tapes. Since this book is from 1978, I don't know if the address is still good. Does anyone know if Lisette Scholl and/or some group of people carrying on her work can be reached anywhere? I'd like to get a copy of this out of print book and see what they offer. The address in the book is

P.O. Box 596
Templeton, CA 93465

Did anyone ever figure out what the Vision Care product was? In my
(behavioral) optometrist's office the other day I found a brochure for a
Biopter by Steroe Optical (Products for Better Vision). The picture looks
like the animal you described. The Biopter is a hand held device with
pictures at one end and eye-view thingies at the other end. It doesn't look
like a plastic thing, but it is on a slide. Here is the description:

"Hand held model No. 1 offers a quality home-training unit at
moderate cost. Precision glass optics...designed for ease of use and
durability. Office Model No. 2 in addition to the above, offers 2-lamp
illumination, adjustable table elevation, and special clips to hold
auxiliary lenses, prisms or occluders. Metal plate also provided for
cheirosopic tracing [?]. Biopter test consists of 10 full-color targets in
unique flip-up binding to test phorias, acuities, stereopsis, color
discrimination, etc."

At 11:09 PM 11/18/96 +0000, you wrote:

We need to look at the etiology of blurred vision in order to evaluate the potential effectiveness of Homeopathic treatment . Congenital or structural defects are less likely to respond compared to an acute condition which will have a more favorable response. I have noticed a slight improvement in my refraction (-4.50 to a -4.00) after constitutional treatment. This is about a 10% improvement unexplained by allopathic theories.

Let us look at the different etiologies of blurred vision.

Axial refractive errors.

This is were the eye is normal except for an abnormal length, either too short or too long. It is unlikely that Homeopathic treatment can alter this

structural problem.

Curvature refractive errors.

This is due to changes in the curvature of the cornea or the human lens. Swelling of the cornea due to injury, dehydration of the cornea, cataract formation and keratoconus are examples in this group. Homeopathic treatment can be very helpful in many of these conditions especially if the problem is acute.

Change in the index of refraction

This can be caused by a chemical imbalance in the body and due to the side effects of many allopathic medications. For example in diabetes there is a disturbance in the water balance of the lens which can change the index of refraction. Cataracts can also cause a change in the density of the lens with a change in the index of refraction. Homeopathic treatment can be helpful in this group.

Change in the position of the lens

This can be due to trauma , infection or inflammation of the eye. Homeopathic treatment can be very helpful.

Accommodative spasms/ Migraine

These refractive problems are due to either vascular spasms or muscular spasms. They are very responsive to homeopathic treatment.

As in all cases it is important to look at the totality of the case. We should not limit ourselves to the remedies listed in the EYE and VISION section of the repertory. I have found that there are deficiencies in this section. Hopefully with time, those of us with an interest in the eye will be able to update this section.

Sincerely, Ed

A while back on I SEE, mention was made of the recently published book "Improve Your Vision Without Glasses or Contact Lenses: The AVI Program" by Steven M. Beresford and some other optometrists. Julie Ralls writes:

-----Begin Forwarded message -----

Date: Wed, 11 Dec 1996 15:43:42 -0500

From: JRalls7959@aol.com

Subject: more to book

After reading Beresford et al.'s book I wrote to them in a helpful way telling them how to improve their book. I suggested they add some scholarly reference to back up the material in the book. References from learned journal and all that for skeptical scientists. It turns out that that was their original intent but the editors at Simon and Schuster edited the list out. I will try to send it now as an attached file. I am told it is in WORD 3.0. Feel free to pass it around.

Julie

----- End Forwarded Message -----

I have unattached the file (a Microsoft WORKS file, incidentally), converted it into text format, and append it to this message. --Alex

introducing myself/questions

-

Hi. I just got on this list so I want to introduce myself and ask some questions along the way.

Anyways. I am only 16 years old and have *bad* eyesight (at least for someone my age). I started wearing glasses in gr. 3, and every year I had to change prescription for stronger glasses. By now my eyes are about 7.25 diopters. =(It's really inconvenient to wear glasses and I hate them, but I don't want to wear contacts either because I know lots of people got infections this way. I've always believed that my poor eyesight would heal itself any minute I begin to try, but i never knew what to do. Then, by chance, I found a book in the library about the Bates Method, and I read 3-5 books on VT now. I think the HypnoVision one was the best. I had the best improvements from it but unfortunately, I am not someone who can patiently stick to a schedule, and my eyesight very soon went back to the way they were. Then I accidentally stumbled onto the I See homepage and came *here* immediately. I used to read a lot but after a while I got scared of reading (this is before I learned about VT) and didn't read as much as I used to. I've noticed that after swimming and riding on roller coasters that your eyes get better a bit! This may be because you have to take glasses off to do them but it has to be more than that. With the swimming I think it's also because of the exercise you get (ie. blood circulates to the eyes), and with the roller coaster, well all I can say is it works too. It's really annoying wearing glasses because I have to worry about them breaking or the screws coming out. It's inconvenient and a drag. The bad thing is it gets me down. Sometimes I can't do some things (at concerts/parties) that other people can because I have to worry about my glasses. It already discouraged me in many ways, but I am here and I want to make my eyes better again. By telling the world my goal I hope to make it true. Goal: to have better eyesight and vision by January. (That's when I have to go to the optimist and I don't want to get stronger glasses) So I hope I have the support here

to discard my glasses, I can't be open about this anywhere else, and I guess not much of you would care anyway but I'd like to ask a few questions now:

1. Does anyone feel really insecure without glasses on, esp. in a public place? I'm not comfortable without glasses at school/ on the bus... I feel like since I haven't even seen my own face clearly yet, I don't want others to see me w/o my knowing what I look like.

2. My family does NOT believe this can work. This gets me very discouraged. My bro keeps on bugging me and telling me to put my strong glasses on. My dad is against it too. They feel I'm just too stupid to know what's good for me. They think the optimist people knows everything and I'm just reading some books about eyes with no importance. Anyone knows what I should do to sneak some eye exercise in? Talking to them about it is out of question because I've already tried it with a 2 weeks fight and it got nowhere (the same as my wanting to be a vegetarian).

3. As I've said before, I have little patience to sit and palm for half an hour every day. The longest time I've palmed was 10-15 min and I almost fell asleep. Any advice on what kind of exercise to do, how to do them, schedulings, etc? BTW, I have myopia and astigmatism.

4. yeah, is it OK to wear a much weaker pair of glasses in front of a computer? I don't need to squint but I do have to lean forward a little, although now I can sit up further from the screen as time goes on. I guess it helps the eyes too as long as you rest a lot. Just wondering if it can do any harm to my eyes.

5. I've tried VT a little before but it's very discouraging when your eyes get a *little* better for 1/2 a day and then get worse again. Should I be aware of some things that I might have been doing wrong? and anyone with success please tell me about it and how you did it. I know some are in the archive but I'm still trying to sort through everything.

6. Does playing piano cause any problems to the eyes? I've read somewhere it can cause strain to eyes unless you change you attitude toward piano (or whatever hobbies/things you have to do).

Anyways, I've wasted all your precious time with this pointless post and I'd like to thank you for reading this. Hopefully some of you can take the time to answer me. You can just email me back privately so we won't annoy anyone with stuff everyone already knows. Any help is greatly appreciated. My address is macy@ipoline.com .

Thanx in advance.

macy

Hi Caroline,

The last time the salesman spoke to me was that they didn't appoint an agent in Australia so you can't get one there. But yesterday he called me and said that he would courier one over if somebody wants one. I am not sure whether that's a good idea or not, I would classify it as fragile equipment.

Today, I saw Graham Stanton in the lift. I understand he comes down quite often. Perhaps you can ask him a favour to carry one over for you if you are interested. I will send you a brochure if you give me your address.

I believe any product would work differently on different people. I am not trying to sell this product but I believe that in strengthening the eye muscle it would help our vision. I had an old friend who told me her son has a lazy eye. He had to wear special glasses which had no degree on one eye and about 475 degrees on the lazy eye. This was to prevent him from only seeing with the good eye and have the lazy eye continue to deteriorate. As the equipment has helped my niece who also had lazy eye, I then recommended her to try it. Having recommended her on this, I naturally am curious to monitor the progress. One course of treatment is 3 to 5 weeks, and the first course of treatment should see tremendous result especially for children. After the first week, I called her to check on the boy's progress. She said he could read 4 lines further down with the lazy eye now. After the second week, I called her again, she told me she hasn't checked which line he could read yet but the son has the tendency to remove his glasses away preferring to see without the glasses. But she would nag him to wear it for fear the he would fall into the habit of only

seeing with the good eye. I told her she should ask him why he did that, it could be because the glasses is now too deep for him and he feels it tiring to look through it and that she should use an eye patch if she wants him to use the lazy eye. She told me she has a doctor's appointment soon for the boy to check the eye sight and would let me know.

I checked with her again on the doctor's appointment. She told me at first the doctor checked and told her the degree has reduced to 300 and then explained to her that there was too much variation, and that he needs to use the eye drops to relax the child's eye muscle and check again. She didn't understand what that means. After putting the muscle to "sleep", he then checked the degree again and found it back to 475 degree. He was satisfied now and told her she could go home and come back again one year later.

How one interprets this whole episode is up to individual. But Meng Hong was convinced that her son's eye sight has improved and would look for another optometrist end of this month to make a new pair of glasses. I would let you know more if you are interested to follow up.

Your baby will be coming soon, please take care and keep me informed of the arrival.

I wish you a Merry Christmas and a Happy New Year,
Cheers,
Mei

Mei

Did your salesman call round? If he didn't, perhaps you could give me a number to ring in Singapore and I can find out some more directly?

Many thanks
Caroline

From: Dawn Isaacson

To: Richards, Caroline

Did anyone ever figure out what the Vision Care product was? In my (behavioral) optometrist's office the other day I found a brochure for a Biopter by Steroe Optical (Products for Better Vision). The picture looks like the animal you described. The Biopter is a hand held device with

pictures at one end and eye-view thingies at the other end. It doesn't look like a plastic thing, but it is on a slide. Here is the description:

"Hand held model No. 1 offers a quality home-training unit at moderate cost. Precision glass optics...designed for ease of use and durability. Office Model No. 2 in addition to the above, offers 2-lamp illumination, adjustable table elevation, and special clips to hold auxiliary lenses, prisms or occluders. Metal plate also provided for cheirosopic tracing [?]. Biopter test consists of 10 full-color targets in unique flip-up binding to test phorias, acuities, stereopsis, color discrimination, etc."

I've asked Mei for the brochure and will send you all any appropriate details. The company is in Singapore but I could easily ring them and see if they distribute within America.

Caroline

[snip]

I will send you a brochure if you give me your address.

I know this was discussed before, but without a conclusion as I recall.

I often wonder as I look out of a bus window whether to focus mainly in the near distance where things are a little blurred but not too bad, or the far distance where things are very blurred.

Then something occurred to me. People keep saying that high myopes improve a lot more easily and quickly initially (and when compared with low myopes).

Isn't this evidence for providing the eyes with a greater rather than a lesser amount of blur (even though logic tells me to 'give my eyes a chance' with a lesser amount)?

Thanks Ed for the info on homeopathics. I will check out the web site too.

I have a bottle of Vision Complex by Nova Homeopahics near my computer at work (not too near) that is supposed to help with tired or strained eyes from computer use, driving, etc. It does seem to help.

Ingredients:

Aurum metallicum 12X
Belladonna 12X
Cactus grandiflorus 4X
China officinalis 8X
Conium maculatum 8X
Curare 12X
Gelsemium sempervirens 12X
Phosphorus 10X
Ruta graveolens 6X
Veratrum album 6X

I know my eyes tend to be dry as when I first put drops in them, everything is much clearer.

Macy,

just briefly to reply to your note:

1. whatever you do, do not give in to negative, discouraging comments on your approach. You are on the right track!

2. VT is NOT an 'instant happiness'!!! It take perseverance, desire to see the world clearer and become a different (better) person. That is what happens to one, when one embarks on this journey.

3. read and rest and read and rest - your eyes! Learn as much as you can to equip yourself with the knowledge you need to improve your vision. The VT with it's philosophy should become an integral part of your daily being. Learn to look at the world with open heart, get excited about the challenge!

4. one of many good books with exercises and the background is Dr Michael Robert Kaplan Book - Seeing Without Glasses (used to be called 'Beyond 20/20').

This book provides the background and "how to" information to increase your vision fitness. It includes self-analysis questionnaires, vision fitness games, nutritional information, movement and exercise recommendations and "insights" into your mind's eye.

An other one - just giving the spiritual uplift is Adouls Huxleys: The Art of seeing (did you know, that the writer, A. Huxley was large part of his life blind before he regenerated his vision???)

5. Get on <http://www.sunshine.net/www/0/sn0011/> page. You find a bunch of other information. (You can order the above book in here).

6. I have improved from -18.00 (yes you read it right) to -11.00 - have also astigmatisms. It took me 2 - 3 years. Daily stress does play large role in the progress or regress.

7. Learn to control your fatigue and stress level. Learn to meditate. There is alot of literature on the subject in a library or a bookstore.

Learn to follow your subconscious mind. It will tell you if you are on the right track - trust yourself.

That is in summary what I would recommend. Good luck. Katerina

Hi. I just got on this list so I want to introduce myself and ask some questions along the way.

Anyways. I am only 16 years old and have *bad* eyesight (at least for someone my age). I started wearing glasses in gr. 3, and every year I had to change prescription for stronger glasses. By now my eyes are about 7.25 diopters. =(It's really inconvenient to wear glasses and I hate them, but I don't want to wear contacts either because I know lots of people got infections this way. I've always believed that my poor eyesight would heal itself any minute I begin to try, but i never knew what to do. Then, by chance, I found a book in the library about the Bates Method, and I read 3-5 books on VT now. I think the HypnoVision one was the best. I had the best improvements from it but unfortunately, I am not someone who can patiently stick to a schedule, and my eyesight very soon went back to the way they were. Then I accidentally stumbled onto the I See homepage and came *here* immediately. I used to read a lot but after a while I got scared of reading (this is before I learned about VT) and didn't read as much as I used to. I've noticed that after swimming and riding on roller coasters that your eyes get better a bit! This may be because you have to take glasses off to do them but it has to be more than that. With the swimming I think it's also because of the exercise you get (ie. blood circulates to the eyes), and with the roller coaster, well all I can say is it works too. It's really annoying wearing glasses because I have to worry about them breaking or the screws coming out. It's inconvenient and a drag. The bad thing is it gets me down. Sometimes I can't do some things (at concerts/parties) that other people can because I have to worry about my glasses. It already discouraged me in many ways, but I am here and I want to make my eyes better again. By telling the world my goal I hope to make it true. Goal: to have better eyesight and vision by January. (That's when I have to go to the optimist and I don't want to get stronger glasses) So I hope I have the support here to discard my glasses, I can't be open about this anywhere else, and I guess

not much of you would care anyway but I'd like to ask a few questions now:

1. Does anyone feel really insecure without glasses on, esp. in a public place? I'm not comfortable without glasses at school/ on the bus... I feel like since I haven't even seen my own face clearly yet, I don't want others to see me w/o my knowing what I look like.

2. My family does NOT believe this can work. This gets me very discouraged. My bro keeps on bugging me and telling me to put my strong glasses on. My dad is against it too. They feel I'm just too stupid to know what's good for me. They think the optimist people knows everything and I'm just reading some books about eyes with no importance. Anyone knows what I should do to sneak some eye exercise in? Talking to them about it is out of question because I've already tried it with a 2 weeks fight and it got nowhere (the same as my wanting to be a vegetarian).

3. As I've said before, I have little patience to sit and palm for half an hour every day. The longest time I've palmed was 10-15 min and I almost fell asleep. Any advice on what kind of exercise to do, how to do them, schedulings, etc? BTW, I have myopia and astigmatism.

4. yeah, is it OK to wear a much weaker pair of glasses in front of a computer? I don't need to squint but I do have to lean forward a little, although now I can sit up further from the screen as time goes on. I guess it helps the eyes too as long as you rest a lot. Just wondering if it can do any harm to my eyes.

5. I've tried VT a little before but it's very discouraging when your eyes get a *little* better for 1/2 a day and then get worse again. Should I be aware of some things that I might have been doing wrong? and anyone with success please tell me about it and how you did it. I know some are in the archive but I'm still trying to sort through everything.

6. Does playing piano cause any problems to the eyes? I've read somewhere it can cause strain to eyes unless you change you attitude toward piano (or whatever hobbies/things you have to do).

Anyways, I've wasted all your precious time with this pointless post and I'd like to thank you for reading this. Hopefully some of you can take the time to answer me. You can just email me back privately so we won't annoy anyone with stuff everyone already knows. Any help is greatly appreciated. My address is macy@ipoline.com .

Thanx in advance.

macy

Is there any mechanical linkage between the two eyes that keeps them pointed at the same thing in normal people and that keeps them pointed at different things in some people?

Or is it just a habit?

Hi Caroline

Here's what I've learned (IMHO) working with the vision therapist (and the accomotrac)--

The idea is to look "through" things. Different ways of doing this include trying to use (pretend) x-ray vision, pretending that what you want to see isn't there and seeing what's behind it, and instead of looking at it, point your eyes at it but then try to see through the back of your head. While these ideas seem silly, they apparently work to reduce accomodation, because I get a good response from the machine.

I also read (in probably more than one book) you're supposed to continually change your focus, ie. Look at an object further away to see one slightly nearer, then look close, then far away, then at your target again. One other thing that has worked, which is hard to explain and probably is only a result of "seeing correctly" is actually (well, maybe not really) physically extending my eyeballs out towards my target as I'm trying to see through it. This action(?) gets GREAT results from the machine.

As a high myope, my experience is that all of the above produces noticeable results. Last night we went to see Les Mis (Broadway). Someone (sorry, I don't recall who) suggested watching movies more than once with reduced (or no?) prescription. The idea, I think, is that if you're familiar with something, your memory will be able to fill in the gaps. Since I've seen it before (actually, it was a last minute thing & I had no choice), I wore an approx 1/2 prescription (-5.00). I used every technique I could recall, especially the above (also outlining things with your eyes, seeing in-between objects instead of focusing on them). Surprisingly, I think I enjoyed seeing it more this time than last! Rather than focusing on

details, I focused on the big picture & saw more of what was happening on stage. In the past, I always felt like I was missing things because I only focused on one thing at a time (ie. an actor's face, as opposed to everything that was going on on stage).

As far as focus was concerned, yes, things were a little blurry, but it didn't bother me too much. And after the show it felt like everything was more in focus. It might be that after focusing in the distance (and continually changing my distance focus as I moved my eyes around & throughout the stage & tried to see through things & in 3-d as much as possible) for an extended period of time (the play is about 3 1/2 hours), my near -distance focus may have improved.

On the other hand, last week was filled with crises, and as a result the whole week was what the therapist calls "monovision" meaning I could only see one thing at a time, in a very small field of vision. My eyes got worse again, and I've spent all this week trying to make up what I lost last week. So while maybe it's easier for high myopes to tell what works & what doesn't because it causes more dramatic results, all is not necessarily easier for high myopes: I think we tend to slip back into the old patterns much easier.

BTW, since you mentioned the bus, here is my bus routine: No glasses (believe it or not), continually moving my eyes out the window to things in the bus, through people around people & between people. If I'm wearing my reduced prescription contacts, I read, but every paragraph or so I look up, out the window, etc. The idea, as I see it, is not to focus on anything, but just see everything and expand the visual field. Another thing worth mentioning: smiling gets a good accomotrac response! :-) (And on the bus it gets stares from people wondering "Why is she so happy at 6am????") ; -)

If anyone with similar experience has read this far down (this is really long & probably not too interesting), my current struggle is which eye to look through for what. I can't seem to make my eyes work together (I think I had build-in monovision because one eye always did the reading with less myopia and some astigmatism, while the other did the distance stuff with higher myopia and no astigmatism). I feel like I am constantly trying to make the weaker one do what it didn't do before & it's VERY tiresome (& sometimes confusing).

Any ideas?

Hope this helps, and good luck!

Dawn 8-)

Hi Macy!

I'd like to answer your email, although I'm not a doctor or anything at all. I'm just like yourself, and two months ago (after months of reading books only) I started vision therapy with a behavioral therapist.

At 01:12 AM 12/13/96 +0000, you wrote:

>I am only 16 years old and have *bad* eyesight (at least for someone my age). I started wearing glasses in >gr. 3, and every year I had to change prescription for stronger glasses. By now my eyes are about 7.25D. =(

Exactly the same story as mine. Only I'm almost 30 and my full (eyeglass)prescription is above -9.50D.

>It's really inconvenient to wear glasses and I hate them, but I don't want to wear contacts either because I know lots of people got infections this way. It's really annoying wearing glasses because I have to worry about them breaking or the screws coming out. It's inconvenient and a drag. The bad thing is it gets me down. Sometimes I can't do some things (at concerts/parties) that other people can because I have to worry about my glasses.

There's no reason why you should have to wear contacts if you don't want to, but I can tell you that people only get infections because they handle the lenses improperly. Nowadays, with lenses you throw away each day, the risk is almost nonexistent.

I love my contacts for several reasons: My glasses press on my sinuses and nose, but my contacts allow me to breathe better; I feel like an ugly

duckling hiding behind thick frames (small frames won't support my thick lenses); I find it easier to participate in sports; my peripheral vision is not impeded with contacts; I can actually fix my hair much nicer and put makeup on properly with contacts, but with glasses I can't do it right or not at all.

The only drawback to contacts is that you can't take them off easily. But at my prescription, I get too frustrated going "cold turkey" to do that. Instead I wear contacts in a weaker prescription and when I do exercises I put plus glasses over them (reading glasses about \$15 from the drug store) if it's not convenient to take them off. At home I have glasses that are 1/2 my prescription and pinhole glasses (to wear alone or over my half prescription when I get frustrated).

>I've always believed that my poor eyesight would heal itself any minute I begin to try, but i never knew what to do. Then, by chance, I found a book in the library about the Bates Method, and I read 3-5 books on VT now. I think the HypnoVision one was the best. I had the best improvements from it but unfortunately, I am not someone who can patiently stick to a schedule, and my eyesight very soon went back to the way they >were. Then I accidentally stumbled onto the I See homepage and came *here* immediately.

This is exactly how I found out, too. I also have problems sticking to a schedule, but now I look forward each day to reading my ISee emails and immediately afterward spending a few minutes doing some training exercises. All other times I just keep reminding myself of my goal and trying to incorporate exercises and good visual practices into my day.

>Goal: to have better eyesight and vision by January. (That's when I have to go to the optometrist and I don't want to get stronger glasses)

Someone posted an email on how to "trick" the optometrist into giving you weaker glasses. Probably the best bet would be to tell him what you're doing first, then try to convince him, & if it's a no-go then find a new optometrist.

>1. Does anyone feel really insecure without glasses on, esp. in a public place? I'm not comfortable without glasses at school/ on the bus... I feel like since I haven't even seen my own face clearly yet, I don't want others to see me w/o my knowing what I look like.

I could NOT deal with work without corrective lenses. A 20/50 (?) prescription is the most I can handle at work, and even then I still feel uneasy. The bus is much easier, but when you're in school the bus is a social time, so that might be why you feel uncomfortable. When I was in school, the most horrible thing was not recognizing people because my glasses were never strong enough. People thought I was anti-social or

really quiet (even though I was active in many activities). And that made me more withdrawn, more depressed, and more myopic. These things seem to reinforce themselves. Contacts helped me to see my own face and become more comfortable, and as a result everyone learned that yes, I did have a personality!

>2. My family does NOT believe this can work. This gets me very discouraged. My bro keeps on bugging me and telling me to put my strong glasses on. My dad is against it too. They feel I'm just too stupid to know what's good for me. They think the optimist people knows everything and I'm just reading some books about eyes with no importance. Anyone knows what I should do to sneak some eye exercise in? Talking to them about it is out of question because I've already tried it with a 2 weeks fight and it got nowhere (the same as my wanting to be a vegetarian).

We must have the same family!!! Ok, this is what I did: First, convince Mom. If she understands, the others will at least be accepting. My mom doesn't have really bad eyesight, but I showed her some accupressure stuff and a few of the exercises so that she was able to see that the exercises DO work. She still thinks I'm wasting my money and time, but since I've dropped more than one diopter in less than 2 months, she sees that I'm happy and doesn't argue with me any longer. As for the men, it has been statistically proven that females are more prone to things such as depression. We have been discussing the fact that myopia is highly related to emotions, and there is no doubt in my mind that depression and myopia are intricately related. I pretty much ignore my brother (who, everytime I get a cold, tells me it's all in my mind), and as for Dad, he's so stuck in his ways he can't change his toothpast brand without going bonkers. But Mom convinced him to leave me alone. BTW, Mom & bro's vision isn't too bad, Dad & I share high myopia. Periodically I email Mom with stuff from this list. But I don't live with my parents & bro. My boyfriend is not really supportive, but he is understanding. At work I told some colleagues about it & was surprised when they were interested. Although no one else is actively doing it, we discuss it often and they are surprisingly supportive.

As far as sneaking, I don't think there's any need to do that, but my friend Debbi was great at it in high school. I could ask her for sneaking techniques if you like. ;-) Instead, consider working the exercises into everyday activities so they're not noticeable. Living at home and trying to be vegetarian could be difficult if no one agrees (you have to change your whole diet and it would require twice the cooking). But improving your vision only requires you to do it. Just do it when they're not around, in the bathroom, at school, at night (see below).

As far as eyedoctors being "all-knowing," that's baloney. No one is all-knowing, no one is perfect. There is one theory that optometrists don't like vision therapy because it takes away from their profits from

eyeglasses. Who knows. I believe that glasses are addictive, but I'm not so sure about the paranoid theory, either. Either way, if you're doing something positive, as long as it isn't going to hurt you, all you're losing is your time. That's not such a bad risk, is it?

On the other hand (sorry about the repetition on this story, but I just love it), my best referral for vision therapy came from a Laser-PRK surgeon. I was totally ready for it, and he was even running a special for people with high prescriptions (because it's only approved in the US for up to -6.00D) and I would have been a perfect candidate. Although he is skeptical that VT will work (he says maybe 1 or 2D, if I'm persistent), AND he lost a patient and \$\$, he referred me to the optometrist I am seeing, who has attended many of the surgeon's seminars. Both doctors were so wonderfully open-minded that it encouraged me even more.

>3. As I've said before, I have little patience to sit and palm for half an hour every day. The longest time I've palmed was 10-15 min and I almost fell asleep. Any advice on what kind of exercise to do, how to do them, schedulings, etc? BTW, I have myopia and astigmatism.

Again, same here. I am VERY busy: I work 10+ hours/day in a high profile, high stress job, karate/yoga a few times a week, plus whatever play the community theatre is working on. After that, cleaning the house, spending time with a boyfriend, and keeping up social interactions leaves no time for anything else. I no longer palm (unless my eyes get really tired or dry from the computer). Per recommendations from the group on ISee, I bought an eye pillow (\$7 at Bed, Bath & Beyond or \$10 at the Body Shop) and now I put it over my eyes before I go to bed and do my "palming" exercises. Then I fall asleep. On the weekends, if I'm really stressed I take a few minutes out to sit with my eye pillow on my eyes in the bath. As for the other exercises, I don't do much that I can't work into day-to-day activities (although I am going to a vision therapist for accomotrac (biofeedback) and have posted a lot of the exercises the therapist has taught me). Other than the eye pillow at night and the accupressure (From the Lieberman book) once in the morning (5 min) and before the eye pillow (10 min, tops), I spend, actively, less than 15 min per day on actual exercises.

>4. yeah, is it OK to wear a much weaker pair of glasses in front of a computer? I don't need to squint but I do have to lean forward a little, although now I can sit up further from the screen as time goes on. I guess it helps the eyes too as long as you rest a lot. Just wondering if it can do any harm to my eyes.

The first thing my behavioral optometrist did was to prescribe what he calls "stress lenses." All they are is a +.75 prescription. They are the same as reading glasses you buy from a drug store. I wear them over my contact lenses when reading or computer-ing. From what I understand, it is exactly

the same as wearing a weaker prescription. (For some reason, that doesn't make sense to me, but I don't think a weaker prescription could ever hurt your eyes, as long as you don't resort to squinting.)

One of my exercises is to put a +2D lens over my uncorrected eye (patch the other one) and look at an eye chart, moving in as far as I need to see the letters clearly. Then I sway back & forth until I can maintain the clarity as I sway backwards. Always keep the eyes wide open, never squint.

>

>5. I've tried VT a little before but it's very discouraging when your eyes get a *little* better for 1/2 a day and then get worse again. Should I be aware of some things that I might have been doing wrong? and anyone with success please tell me about it and how you did it. I know some are in the archive but I'm still trying to sort through everything.

Some things to watch when you notice your vision getting either worse or better: What did you eat that day? Are you happy, sad, frustrated, depressed, relaxed, etc? Have you been straining? What time of the day is your vision better/worse? How is the lighting?

My eyes are always getting better and worse. Always better when relaxed, especially during lunchtime walks when it's sunny out, always worse under stress.

>

>6. Does playing piano cause any problems to the eyes? I've read somewhere it can cause strain to eyes unless you change you attitude toward piano (or whatever hobbies/things you have to do).

I don't understand about "attitude toward piano." I have played piano since I was in 5th grade (I started late when an accident caused me to give up dancing), have played professionally and for fun. I know that when I practice, if I get frustrated it gets harder to see the notes. I almost quit in college because I couldn't read the music that far away anymore. Now I think playing piano IMPROVES my vision. (As long as I stop BEFORE I become frustrated with whatever I'm playing.)

**Please email me back with what you mean by playing piano causing eye problems. If you can, please include info on your piano playing.

>Anyways, I've wasted all your precious time with this pointless post and I'd like to thank you for reading this. Hopefully some of you can take the time to answer me. You can just email me back privately so we won't annoy anyone with stuff everyone already knows. Any help is greatly appreciated. My address is macy@ipoline.com .

I kind of feel the same, like I'm wasting people's time (especially since I'm not a professional or anything and all of this is only opinion), but on the other hand, they have the choice not to read this, and yet it may

benefit someone who's new to the list or hasn't heard of it. Isn't the whole point of the list to hear EVERYONE's ideas, no matter how good or bad, so we all can have the benefit of everyone else's experiences?

>
Hope this helps!

Good luck & remember that unless you're having fun doing something, you won't want to do it.

Dawn 8-)

 - *Date:* Sat, 14 Dec 1996 11:03:35 -0500 (EST)
 - *Sender:* owner-i_see@indiana.edu
-

hi. my name's eileen. i've posted to i see before, but no one really responds much. i am 34 now, and i also have worn glasses since age 3. i used the hypnovision techniques in lisette scholl's book and dropped 2 diopters in 2 months. that was 2 years ago. i am not sure what has caused the plateau, but a lot of other stuff has happened since then that may be related. not the least of which has been weird flashback emotional states related to stressful traumatic childhood experiences.

after reading some posts by a former i see member, "Elena", i looked at my journal from the time period of the great changes in vision, and it coincided exactly to when i was doing yoga. Elena mentioned that she thought doing yoga had a lot to do with her changes. now i am attempting to get a yoga habit happening again, but my self discipline leaves a little to be desired (then, i was recovering from knee surgery and yoga was the only thing i could do.... i had a tape by Bikram Choudry that i got from the Kripalu Institute in MA, where i had taken a self esteem course.) my intent is to eventually do a way with wearing glasses entirely, but my understanding has grown to "see" that your eyes are just one small part of your total system.

the interesting thing is that i first thought about my eyes after reading books by Brian Weiss about reincarnation, and when i went to get books about regression therapy i thought, "Hey, why don't i work on some stuff * now * instead of looking back? ... so i got Hypnovision from the library in the same trip that i got the reincarnation therapy books at, and started it.

it is funny that the last chapter of Scholl's book is titled, "regression" i haven't been regressed yet, tho it may be a step i will take if it comes my way. i say, don't talk to your family about it. just make time to do

the relaxation and especially the acupuncture massage daily. it might seem ineffectual, but even tho i have mostly stopped doing things, (i am a graduate student in medical illustration now, and have not been good at budgeting my time!) i have not lost any of the ground i gained. my original prescription was -9.50 sphere, -3.50 cylinder, and now it is -7.50 s, -1.75 c. i intend to keep going. it is a journey into discovering yourself. you should be proud that you are dealing with this at age 16. you are way ahead of the game. stick with it. write in a journal. read deepak chopra, and a terrific author i just discovered is Caroline Myss. maybe you can find stuff at the library. she's a medical intuitive. very cool stuff. another great book to expand your awareness is "Many Mansions" by Gina Cerminara. enough pontificating. eileen

yes, i reach for them first thing in the morning. the times i walk around with lower prescriptions than i need, i get paranoid (well, not much) that people will be angry with me for not recognizing them and not "saying hi" but it's all about learning to "be comfortable with the blur"

i made a tape and use it morning and evening. if you share a room with a sibling, get a walkman. put the tape on FIRST THING. after a while, learning to "feel" and relax each of the parts of your body becomes a great gift. you can make the tape so that it takes only 20 min... you can do it. and if you have a walkman, maybe you can add a 5 minute induction and palm at lunchtime after relaxing your body. relaxing is the KEY.

don't know. have similar questions, since right now i have to use a
computer a lot. mattera fact, i try not to log on to email much so i
don't have to read anymore than i need to.

i would work on improv and memorized pieces. try to do away with
straining to look at tiny little black dots! play something else for a
while, improvise!

Hello everyone...has anyone had any positive experiences with accupressure for vision problems? Are there any good web sites on this that show the techniques? Thanks for your response on this! Dave Campano(davecam@prgone.com)

> far
> distance where things are very blurred.

I would say to look at something that creates the maximum amount of blur, but still allows you to read it. If you look at something just at the far-point (before it becomes blurry) your accommodation will be essentially neutral.

If you start to blur the image, you will achieve "active relaxation" of the ciliary muscle, which it what works towards reducing myopia. If you look at something so blurry that you can't even read it, you eyes will not even attempt to focus.

That's what makes plus lenses so effective. Looking out the window of a bus, what are the odds of finding something in just the right degree of blur? And when you do, how long do you get to focus on it? If you wear plus lenses for reading, you can find the perfect range, and work on it for as long as you are reading. You can push the reading material to the maximum blur point where you can still read it. Then, you can keep "pushing" while you are reading, to try to extend that blur point even further.

> Then something occurred to me. People keep saying that high myopes
> improve a
> lot more easily and quickly initially (and when compared with low myopes).
> Isn't this evidence for providing the eyes with a greater rather than a
> lesser amount of blur (even though logic tells me to 'give my eyes a
chance'

>
> with a lesser amount)?

I think you hit it right on the head. Keep the image as blurry as you can and still read it. Any less blur, and you aren't doing any good. Any more, and you're not "giving your eyes a chance".

The best way to effectively debate someone (in any subject) is to become as educated as possible on the subject. Learn the speak the Optometrist's / Ophthalmologist's language. Be able to quote scientific studies that support your opinions.

I hate to sound like a one-man advertising machine, but my advice is:

Order this book:

THE MYOPIA MYTH; The Truth About Nearsightedness and How to Prevent it.
By Donald S. Rehm,
International Myopia Prevention Association
RD 5, Box 171
Ligonier, PA 15658

(\$15 including S&H)

Best 15 bucks I ever spent!

This book very effectively takes scientific concepts and explains them in a manner that anyone could understand. I believe it is the best single-source that will educate you on the subject. It is a pretty easy read, too.

Here's an interesting phenomenon...let's see if anyone can help be figure it out:

My contact prescription is -3.00 (left) and -3.5 (right), only my right eye has worsened to about 20/525 (-5.25). When I'm in class, I can see the board fine with my corrected left eye, but I can only see about 50-75% as far with my right. And here's where it gets weird...Outside, I try to look out as far as I can into the distance. This I can do fine with the left, but again the right can only see 50-75% as far. But the difference between this 50-75% in the class and 50-75% is prob'ly about 50 miles at least. Why this percentagology? Any answers?

Katy

Hi Everyone!

Can anyone help me? My current struggle is which eye to look through for what. I can't seem to make my eyes work together (I think I had build-in monovision because one eye always did the reading with less myopia and some astigmatism, while the other did the distance stuff with higher myopia and no astigmatism). I feel like I am constantly trying to make the weaker one do what it didn't do before & it's VERY tiresome (& sometimes confusing).

Anybody have any ideas (exercises, etc) on how to help this problem?

Thanks!

Dawn 8-)

Dawn,

Have you tried patching?

If you think one eye is trying to do all the reading, try covering it with an eye patch and reading with the other eye. If reading without corrective lenses is uncomfortable, use your reduced prescription glasses.

Practicing distant vision with a patch could help too, though it becomes a matter of first learning to judge distances and the relative positions of objects without the benefit of stereoscopic vision (try drinking a glass of water, or bringing a spoon to your mouth, with one eye patched -- it's a little weird). Walk around at home, or some other familiar place where you're unlikely to hurt yourself by bumping into things, with each eye patched.

You can get an eye patch at most pharmacies for a couple bucks. They (more or less) fit underneath glasses, so you don't have to go cold turkey and get frustrated.

By the way, you don't say which of your eyes is dominant, the more highly myopic one or the more highly astigmatic one? Oddly enough, my eyes are similarly arranged: the one with higher myopia has half the astigmatism of the other. The dominant eye is the more highly myopic one. Are either of these arrangements common, anyone?

I'm a little hesitant to give folks advice about eye exercises and habits, since my own efforts at improving my vision have been only marginally successful to date. If anyone would care to comment on the above or expand on it, I'd love to hear about it.

Thanks all,

Zaven

Hi Group:

Macy and I have been discussing the effect of playing the piano on eyesight. Has anyone had any negative effects (increased myopia/astigmatism) from playing the piano? What have you done to alleviate it?

Thanks!

I have a +2D lens that I use on one eye at a time w/a patch over the other. I can't do this for more than a few minutes at a time because 1) I get dizzy (no airhead jokes, please) 2) I can't see w/out my glasses to do most things (even washing the dishes--that's what I've been working on)

I will try it around the house under my 50% glasses. Thanks for the idea. Any ideas for while at work? (I spend more than 10 hours a day, sometimes working w/the public.)

>

Yes, oddly enough I'm EXACTLY the same. But once in a while it changes--I think it may be stress related.

Here's another thing...I've been working w/the accomotrac w/ a vision therapist. At the beginning, my left eye (higher myopia, no astigmatism) seemed to improve faster. The last three weeks, my astigmatic eye has gotten better feedback (has been accomodating less).

Here's something I just remembered: Just before I started vision therapy, I attended a PRK seminar. The doctor pretty much admitted that the surgeries (PRK, RK and all the derivatives) cause presbyopia. To help with this, he said he has purposely undercorrected one eye for reading, in other words, purposely causing monovision. My dad was given monovision by his ophthalmologist so that he could wear contact lenses. (I don't know the details, just that his eyes are in the -15D range or more.) The PRK doctor said some people like it (monovision), others don't. I know my dad didn't like it because he went to a new doctor. Any thoughts, anyone?

>I'm a little hesitant to give folks advice about eye exercises and

>

Please don't hesitate! Ideas are ideas, and any one idea can help anyone improve, even if it's just a little bit. If it's a bad idea, it won't work & no one will do it.

Thanks for your help!

Dawn 8-)

Hi Group!

I'm getting to the point where I'm reading so much that I don't remember where I read things!

Can anyone help me find the following:

I remember reading statistics about myopia as it relates to development of girls and boys, including statistics as to the ages of girls when they develop myopia (and how much myopia) and the ages of boys.

Thanks all for your help!

Dawn

Dawn wanted some advice on exercises that would get the eyes to work together. One exercise that has worked for me is the "string" or "yardstick" exercise. Here's an easy-to-explain version. Hold a long stick pointing out from your nose and slide your finger along the stick. Look at your finger. You should see two stick images (one coming from each eye) crossing at your finger. As you move your finger towards the middle of the stick, you will see an "X". Towards yourself, you will see a "V" and so on. Another way to do this is to perch paper clips (or clothes pins) on a yardstick and shift your focus from one clip to another, always keeping the two crossing images of the yardstick in view. Another way to do it is to tie a string with beads in it to a doorknob and pull it out towards yourself.

Try it and let us know what you get!

I don't know the answer, but I can point you to the people who have it.
There is mailing list called "MYOPIA-NET" which you can subscribe to by
sending

subscribe myopia-net

to <Maiser@vision.eei.upmc.edu>. I'm subscribed to this list and it is
quite dead -- about two messages in the last month. But I do know that the
world's authorities on myopia development statistics such as prevalence
among various ages and sexes subscribe to the list. They also could give
you more information on the latest research on myopia in laboratory
animals.

Just wanted to through in my two cents. I noticed in my school everyone i know who plays the piano is myopic.

I not trying to scare anyone :)

Have fun,

Dawn Isaacson's reply:

Can you explain why patching an eye would bring up strong emotions? I've
tried it for about ten minutes today, and yes, I agree it's tiring.

One of Bates clients was a little girl who could see the moons of jupiter
with her naked eye. She became myopic when she had to do math problems
which she hated. Relaxed mind = perfect vision, tense/upset mind = visual
impairment.

Jacob Lieberman, an optometrist and vision improvement teacher, said that
when he first decided to stop wearing his glasses, he found that he could
only keep them off for 15 minutes at a time. Then he would, without being
aware of it, put them back on.

My experience has been that not wearing my glasses brings up feelings of
fear, vulnerability, confusion, grief, sadness and rage. There is, in
vision improvement literature, reference to the myopic personality.

I remember the first vision improvement workshop, lead by Elizabeth Abraham,
that I went to. She distributed some articles and one referred to the
"deadly seriousness" of myopes. I looked around, and in the mirror, and saw
many grim, strained and staring faces. I decided that I did not want to go
around "looking like that".

So patching an eye, especially the dominant one, begins to reverse the process of repression that lead to the original visual impairment. The impairment was often caused by or greatly influenced by emotional trauma - moving to a new home or school, puberty, the death of a parent, seeing something so horrible that the body decides to not see clearly again.

People sometimes quit vision improvement after their vision starts to improve. I think that is because they have not dealt with the feeling issues around their vision.

Also in regards to your desire to have your eyes work together. Most convergence exercises can be used for divergence work if you focus behind the object being looked at and not in front.

Moses

I play the piano and have found that it can indeed be stressful on the eyes. It is a bit like computer programming. However, I find when I sing too, it is much less stressful-- could it be that when I am singing, I am forced to breath more correctly?

I think we are on to something "key" here. Our vision problem is a deep seated "block." It is a subconscious mental block buried into the muscles themselves. A learned habit of tenseness in the muscles. I've been investigating some conscious breathing techniques. Sometimes when I get the deep breathing working properly I can feel these blocks, which I believe are normally subconscious. I can feel an underlying strain around my eyes, (as well as in my lower chest -- other blocks.) At this point, my vision improves noticeably.

A lot of the breathwork I have been reading has some very stunning parallels to the vision work I have been doing. One thing noted is that babies breath normally (deep breathing into the lower lungs, causing the abdominal area to

swell) and as people get older, they gradually revert to shallow "upper chest" breathing. Many many gains can be made simply by re-learning how to breath.

I thought this was very interesting and parallel to Linda Wright's Baby Mode Theory.

Still working on my vision and breathing- just thought I'd want to tell you, I went skydiving today (for the first time) and I did it with no correction! When getting ready to leave my home I had a huge urge to put my contacts in but I overrode that urge and went skydiving (tandem) without any correction . It was such a bright and sunny day- I had no problem at all! And it was a lot of fun.

Here are the books on breathing I am reading:

"The Art of Breathing" by Nancy Zi published by Vivi Co.

"Conscious Breathing" by Gay Hendricks, Ph.D. published by Bantam books

later

I agree with you art. I try to become aware of my breathing and notice
only a slight improvement, but i notice that it sometimes gets difficult
and that I tend to resort back to the short and held
breaths.

Thanks for the titles, i'll scope em out.

Does anybody else have any other book they would recommend relating to
breathing?

Have fun,

-Peter

For anyone who has read *_Take Off Your Glasses and See_* by Jacob Liberman will have read the part on effort and how it is bad. Liberman has an exercise in which he develops your skill of effortlessness. It consists of a row of arrows and you do exercises with them. The arrows are placed on the wall or a board. You start very simply by just turning your head in the direction that the arrow is pointing, you go down the list of arrows until you have done it successfully. The goal of these exercises is to prove that you can only do it when you don't try, the moment you start to think about it you make a mistake. There are several steps and each one is a bit more difficult then the previous. The last step is so difficult that there is no time to think about it, it must be done effortlessly.

The point I am trying to make is that maybe in piano with all of the complexities such as notes that have different lenght and different pitches and many more complexities, that i do not know because of my

ignorance, cause the piano player to develop myopia because there is such a high level of effort. I can remember in my short piano career, how emotionally frustrated i would get when i couldn't get a special fingering exercise. I would try harder and harder and would get no where. Piano being so difficult can cause a lot of adults and especially the younger kids to try to hard and not do it effortlessly because their minds are scripted that if they try they will succeed, thus they getting myopic.

Just out of curiosity does any one know someone who play the piano and is hyperopic ?

Have fun,

-Peter

>I find when I sing too, it is much less stressful-- could it be
>that when I am singing, I am forced to breath more correctly?

I think it's because of the breathing and probably also because when you sing, you have to stretch your facial muscles, by doing that you relaxes your eyes and have better circulation to them. Also you have to sit/stand up properly to get full sound.

macy

Thought you guys might be interested:

Solgar makes a supplement called Billberry-Ginko-Eyebright complex. \$10 or so for 60. I ordered it from The Vitamin Shoppe. (800) 223-1216 for catalog orders; They also have a web page (search The Vitamin Shoppe). This month everything's 30% off. They also have a supplement called Eye Support from Natrol, about \$11 for 60. I've been informed that Natrol is reliable, but I haven't received notice from the company that they don't use aspartame. The two supplements are VERY different. Solgar's formula appears to be the standard vitamins with billberry, ginko & eyebright included. The Natrol formula is all herbal. Anyone interested in ingredients can email me if they're so inclined.

Hope this is helpful,

dc 8-)

Sorry, Katy--

I'm just finding these things & passing along the info. For your use, if you care, or to ignore if you don't like.

Can anyone tell Katy what bilberry and ginko are supposed to do? (There was some info on the faq about bilberry, but I didn't take down the specifics. I'm starting to get information overload.) I read that eyebright is mostly good for eye infections (ie. conjunctivitis), don't know if it actually does anything else.

dc 8-)

PS. Not a "Solgar Guru," since I use Natrol vitamins. ;-) Just thought w/all the hubub about aspartame, people would appreciate the reference. (If you think I'm giving out unwanted info, please let me know & I'll be quiet.)

PPS. Why would I want to cut down a tree? ;-)

Hi

I try to patch each eye for half an hour every night. Having removed the patch and gone into a dimly lit room I've noticed a distinct discrepancy between what my eyes are seeing. If I cover one eye and then the other the cause becomes obvious; the 'just been patched eye' is allowing lots of light in and the 'been unpatched all along' eye hasn't adjusted from the lit room I've just come from and is filtering out too much light. The effect is quite dramatic. It's like having sun glasses (perish the thought!) on only one eye.

So far, so good. What bothers me is that I may have removed the patch 5 minutes or so previously. I had always thought that pupil size changes should take place within a minute or so (adjusting to a darkened room). Is this delay of 5 minutes or more ok or is it related to general vision problems (eg like light sensitivity)? Anyone else noticed this delay (or do you all turn the lights on in every room, even if you're just going in and out quickly)?

Caroline

Hi all. I'm still here, just haven't been able to spend much time on my home computer lately. Which is probably good for my eyes anyway, right. :)

About herbs for better eyesight, I prefer to take them separately/alone and not in mixes. The health food stores usually have plenty of reference material on the different types of herbs, if you want to know more about them.

I bought Earl Mindell's Herb Bible for home reference. Here's what it says about Bilberry and Eyebright...

Bilberry (*Vaccinium myrtillus*)

Bilberry is a well-known folk remedy for poor vision, especially for people who suffer from "night blindness," that is, they have difficulty seeing in the dark. In fact, bilberry jam was given to Royal Air force pilots who flew nighttime missions during World War II. Bilberry works by accelerating the regeneration of retinol purple-- commonly know as visual purple--a substance that is required for good eyesight. European medical journals are filled with studies confirming bilberry's positive effect on vision. Unfortunately, this herb has not received the attention it deserves in the American medical community.

Possible Benefits:

Helps preserve eyesight and prevent eye damage.

Particularly useful for people who suffer from eyestrain or poor night vision.

Good for people who must drive at night.

Helpful for nearsightedness (myopia)

Eyebright (*Euphrasia officinalis*)

Since the Middle Ages, eyebright has been used as a tonic and an astringent. It is especially useful for eyestrain, eye inflammations, and other eye ailments. It can greatly relieve runny, sore, itchy eyes due to colds or allergies.

Possible Benefits:

An eyewash made of eyebright and other herbs can be soothing to irritated and inflamed eyes.

Taken internally, it may help maintain good vision and eye health.

Fusion exercises--getting the eyes to work together

- To: i_see@indiana.edu
 - Subject: Fusion exercises--getting the eyes to work together
 - From: marif@btigate.com
 - Date: Tue, 17 Dec 1996 08:12:29 -0600 (CST)
 - Sender: owner-i_see@indiana.edu
-

Dawn asked for exercises that help the eyes to work together. Alex mentioned a few. One using a yardstick and the other using a string. How did those work for you, Dawn?

I've been trying some of the exercises in Lisette Scholl's book, Visionetics. The book, as you all know, is out of print. :(I sure wish I could buy a copy of this book, it has soooo many really good exercises in it!

Anyway, I liked the fusion exercises Lisette mentions using your fingers. I liked them better than the yardstick and string exercises. And you can do them anywhere, at anytime. You always have your fingers with you. :):):)

Here is the first one and the easiest one...

"Hold one hand in front of your face, and raise the index finger up while holding the rest of the fingers in a relaxed fist. Look up and down that finger with both eyes and then look beyond the finger at an object in the distance a few feet or more away. What happens? Your eyes shift and focus in the distance, and you find that you are looking between two fingers at the object. This optical illusion gives you a gate through which you can look at the world.

If you continue to get only one finger when you look off into the distance, make sure you're holding your finger directly in front of your face and not off to one side. Stand in front of a mirror if necessary or get a friend to help you get your finger directly in front of your nose. Many people find that one finger is much "stronger" than the other image. This means that one eye, the one opposite the strong image, is doing most of your seeing, which you can correct.

...carry the exercise a step further by moving your finger and your head from side to side as you look through your "gate." Slowly move the finger to the left, then to the right, keeping your head moving along with the finger. Take your time; breath, blink! Find an object that is fairly large, and edge it as you swing your gate back and forth. Swing and edge through your finger for two or three minutes.

With this exercise you are helping your eyes to learn to "let go" of separate images, to move quickly from one fixation to another without holding on to a particular image. The tendency to "hold on" to an image rather than edging and taking on many rapid pictures of an object is characteristic of people with poor vision."

End quote.

My observations when doing this exercise:

While holding up my index finger, I would look at the distant object, first with my right eye closed and then with my left eye closed, making sure that the object was visible to *both* eyes and that my index finger was not blocking the distant object in either eye. This also helped me see where the "two" fingers or "gate" should be when I looked at the distant object with both eyes. Once I experienced the "gate", it was easier to do again.

I noticed in Lisette Scholl's book, Visionetics, she has you do palming for a few minutes after every exercise. I know some have found it difficult to palm for long periods of time. But maybe the key to getting benefits from palming is to do it more often, for shorter periods of time.

Lisette says: "...don't do too much palming at first. The amount of time you spend doing the exercises is secondary to your frame of mind while doing them. For the first few times, palm for ten nice long easy breaths and then take your hands away."

Soooo when you are working on the computer--take palming breaks. When you are reading--take palming breaks. Palm during commercials when you are watching TV. Etc., etc., etc.

As mentioned before on this list, I do think it's important to palm with your hands and not just use an eye pillow.

Lisette writes: "Dr. Bates believed that the differing energy potentials of the hands and the eyes resulted in a flow of current from the hands to the eyes, thus increasing circulation, relaxation, and stimulation in the eyes."

Try rubbing your palms briskly together before palming to increase the energy charge transferred to the eyes.

Is there any advantage to taking the vitamins separately (other than that you can control what you're taking better)? I tried to do it that way a while ago & thought I would choke swallowing all those things.

According to the Doctors' vitamin and Mineral Encyclopedia by Sheldon Saul Hendler, MD, PhD. "Homeopathic physicians use eyebright for colds, hay fever, as well as for conjunctivitis. Unfortunately, there are many reports that the application of drops of the tincture in the eye can cause itching, redness, swelling, and other adverse symptoms. Application of eyebright to the eye is definitely not advised."

But then he doesn't reference bilberry for the eyes at all, so maybe he's just ultra-conservative?

Reflections of the moment:

I've been thinking about this issue (the myopic personality), since my personality strategies no longer match the classic myopia profile. I did fit the profile as a teenager, but less before and less after. I think that's a trauma issue, in part. Changing one's personality does not necessarily precipitate massive changes in vision, though some change does come about. For instance, for a number of years I've been working on various forms of physical development such as calisthenics, swimming, running, tai chi, etc. The result has been a far greater sense of ease around other people, more effortless extroverted behaviour, and a greater sense of play and exploration in my visual field. Actual vision improvement, however, has been extremely slow. So taking action to change one's physical, emotional, and cognitive habits has an effect for the better. But VT (and some regression exploration (for me anyway)) still seems to be indicated, however. Probably, I just haven't broken all my routines of 'personality' yet.

In my case, I would say that I chose the myopic behaviour and the vision deterioration followed. The child-rearing aspect would pertain not to specific behaviours related to reading or other activities that were encouraged or discouraged, but rather the model for processing thoughts and emotions. Children take it all in, whether it's consciously encourage/discouraged or not.

Hi Caroline,

You shouldn't be concerned about the time it takes your eyes to fully adjust to the dark. In addition to an increase in the size of the pupil, there's also a chemical change in the retina that takes place after 20-30 minutes of darkness. If you patch one eye for 30 minutes and allow the other only 5 minutes to adjust to darkness, you can expect to see a difference in sensitivity.

Wish I could provide more details. Maybe someone else could?

Zaven

There are (at least) two changes going on in your eyes when you enter a darkened room. One is your pupils getting bigger so more light can get in, as you said. The other is changes in the retina itself as your rods begin to take over your sight from the cones.

Rod vision is called scotopic vision (SC for SCarce photons) and Cone (normal color) vision is called photopic vision (lots of PHOTons).

This list has had a bit of discussion about Cell-Tech and Synergy.

As previously noted, I tried Cell-Tech for a month. I am now trying Synergy.

Cell-Tech is a regime of pills ... six of one kind, four of another, and four of yet another, all taken at different points each day. (You work your way up to those amounts over about a one-week period.)

Synergy is a powder that is stirred into juice, milk, or water and taken once a day (usually upon arising).

Speaking only for myself, I find the Synergy much easier to take ... Since many types of foods/vitamins should not be taken together, fourteen daily Cell-Tech capsules made it difficult to find time to take vitamins for my eyes. Likewise, it was not always wildly convenient for me to take the Cell-Tech capsules.

In contrast, Synergy is taken as soon as I get up, and then forgotten about. Although it obviously doesn't improve the flavor of the juice, it does not taste at all unpleasant.

I just wanted to let you folks know this in case anyone else was worried about the taste.

I am in no way AGAINST Cell-Tech, and fully trust the person who sold it to me. (He's a former colleague of the highest moral and ethical standards, whom I would trust with anything.) I just didn't notice any improvement with it, so took Cheryl's advice and tried the Synergy. So far, I am very pleased.

Dear all,

I've been taking plain old spirulina (bought in bulk at my food coop) for a few days (about half tbsp. a day), and it's doing wonders! The wrinkles I had on my neck and near the mouth have disappeared. There's less gray hair, and I think my bad eye is improving as well. We'll see what happens in a month.

I have read (in "Prescriptions for Nutritional Healing) that spirulina is a complete protein, also rich in vit. C and A, chlorophyll and trace minerals. It tastes disgusting, in my opinion, and smells even worse. I try not to breathe when I take it. It's cheaper than any other "green magma" type food; and I'm sure the flavor could be improved if you put your mind to it.

Ari

Is this the same kind of spirulina one can buy at a health food store (albeit at significantly higher prices)? If so, is there any particular brand you would recommend?

In case other people have this problem....

I found a tendency to see the distant object very clearly and the two fingers in a very hazy way, even fading and disappearing altogether as I continued to look. However, if I bent the finger slightly and unbent it again (not moving the whole hand or my head), the fingers became very clear and the distant object was framed clearly between them, as if they were all at the same distance.

Question: Is the fading normal or does it indicate a lack of "3-d-ness" in my vision? If so, I guess that a separate exercise of keeping the finger visible (ie not letting it fade out completely) is useful?

Caroline

"Hold one hand in front of your face, and raise the index finger up while holding the rest of the fingers in a relaxed fist. Look up and down that finger with both eyes and then look beyond the finger at an object in the distance a few feet or more away. What happens? Your eyes shift and focus in the distance, and you find that you are looking between two fingers at the object. This optical illusion gives you a gate through which you can look at the world.

In my case, I've noticed that when I go about without glasses,
I am much more hesitant to interact with people (especially
people I don't know.) This is because I cannot clearly see their
facial expressions and have a fear that I might misinterpret them.

It's almost a fear of eye contact.. it's a little disturbing

There is no doubt about it, intoversion and myopia go hand and
hand.

As another parrallel to the breathing issue I brought up a little
earlier, in the book "The Art of Breathing", Nancy Zi says that
learning proper breathing habits can eliminate shyness,
soft-spokenness, raspiness in the voice, and greatly improve
self-confidence.

The Vitamin Shoppe, 4700 Westside Avenue, North Bergen, NJ 07047

Phone (800) 852-7153 to order product or LARGE catalog

They also have a web page (Search: The Vitamin Shoppe)

I don't work for this company. The wholesale outlet is near my house & they happen to be selling name-brand vitamins at 30% off this month. I thought it was a good deal, especially since people reported spending \$40 per month at other retail vitamin stores. The two name-brand products I mentioned (Natrol and Solgar) are both under \$12 for 60. Their own vitamins (I've never used them) are usually buy one get the second free or half off.

Hope this helps....

>Can you explain why patching an eye would bring up strong emotions?
>I've tried it for about ten minutes today, and yes, I agree it's
>tiring. Moses

Not only in vision improvement but also in other healing modalities, the left side of the body (and left eye) has to do with opening to your awareness and creativity, female issues, and/or mother (also the Mother Earth) issues. Problems on this side of the body are related to denial, suppression, blockage in these areas. The right side of the body (and right eye) has to do with personal power, manifestation, male issues, and/or father (also God) issues.

Your goal is to be integrated and operating in all modes equally. So when one eye is particularly dominant, the energies related to the other eye do not get expressed very well or very often. Patching the dominant eye, allows the less perceiving eye to get involved. Now depending on why you blurred (near or far) or distorted (astigmatism) these energies/issues, a lot of emotions may be stirred up.

Denny Johnson of Rayid International in Colorado (USA) developed a method of analyzing the eye to determine where your issues are. This is different from the normal iridology technique. Each part of the iris is assigned various emotional characteristics. If you have markings in that portion of the iris, that characteristic is part of your life work. There are positive (in balance) and negative (out of balance) characteristics associated with each position. If you know the angle of your astigmatism, you can look at the chart and see where you have distorted issues. For example, astigmatism in the

forgiveness position in the left eye indicates distorted views around forgiving your mother, other females, and/or the female energies in yourself. Distortion and blurriness on how to use your awareness and creativity in your life. Astigmatism in the trust position of the right eye, indicates distorted issues around trusting men, father, God. Distortion and blurriness on how to use your personal power or manifest things for yourself.

The name of the book is What the Eye Reveals. I don't have it with me but can get the ISBN and their phone number if anyone is interested.

"See" you, Cheryl

Yogi Bhajan is in town right now for Winter Solstice. I went to a class with him last night. He specializes in Kundalini Yoga which uses lots of conscious breathing. Anyhow, I participated without my glasses and was very excited as to how well I could see after each exercise. We have a local Ashram here that I have been to and participated in the Kundalini Yoga, but it has normally been at night and the room was candle lit - some of the most challenging conditions to see under when you have 20/20 clarity. The room was light last night.

Anyhow, I know we have discussed the benefits of yoga and breathing in this list before and now I found something for me that combines them both. I am going to make an effort to go to class regularly now until I can get a routine down at least to do on my own.

Later, Cheryl

I forgot to add that I have been working with a psychotherapist who specializes in Bioenergetics (Alexander Lowen) for the past couple of months. Bioenergetics looks at the body to see where blocks (emotions) are stored and then provides exercises to release them. In particular they watch your ***breathing*** patterns in different positions. Lowen has written many books about this ... "Bioenergetics", "Depression and the Body", "Joy", and more.

-

I was wondering about the success rate when introducing vision therapy to an optometrist. Since I just gave her an indication that my eyes are getting better (Last Feb my prescription was -5.75 left, -5.5 right, yesterday it was -5.5 left -5 right) will that help or hurt, or is this change "in the noise?"

It took about two weeks of palming, reading without correction and wearing reading glasses over contacts at work. (It is not unusual for me to spend 15 hours a day in front of a monitor.)

If I can produce another shift before my followup, I will feel a lot better about bringing it up.

What amazes me is the disbelief I get when bringing it up to everyday folks, even with evidence that it works. If non-optical people react so negatively, it is hard to imagine an optometrist being open to it.

So, what I am after:

- 1) Is a half diopter shift significant at my level of myopia?
- 2) Should I try to "convert" my optometrist, or drive two hours for a behavioral optometrist?

Craig

I think half a diopter is significant. It could be the beginning of a trend 8)

As for looking for a behavioral optometrist - I went to one, but found him more discouraging than the ophthalmologist I had been seeing, so I am back with the old doc. I have not felt the need to convert this guy, I just ask for reduced perscriptions as I need them (I got -2.50 contacts for "using the computer", to be augmented by -1.25's for distance). I actually use the -2.50's for everything but night driving where there are no streetlights, and use +1.50's over them for reading.

I think part of my "myopic personality" was the need I had to be "right" - I really needed others to agree with me! Now, I am satisfied to get what I need without explaining myself. I can let others be who they are, believing what they need to believe, without fighting to "make them see."

Great going! You seem to be on your way....

Yes. It's an improvement, no matter how small.

>2) Should I try to "convert" my optometrist, or drive two hours for a behavioral optometrist?

If your optometrist has a hard time being "converted," you could tell them that it's a weaker prescription you want, or nothing. Another optometrist may be more open minded. If worse comes to worse, the two hour drive would be worthwhile. How often would you have to make the drive?

If I ever go to an optometrist again, I will go to someone that I have never seen. I will not tell them about any vision training/improvement that I have done until maybe after the exam. I will go in with no glasses and let them determine if I need any prescription, fresh, from the beginning.

My experience, in the past, has been they don't believe that you could have possibly changed positively. So they use your initial prescription as the starting point and test you to death until your eyes and body are so tired, your prescription couldn't help but be worse than when you went in. You are challenging their very profession - every thing that they have learned in school.

There are always exceptions I am sure. I live in Florida and have a good doctor in New Hampshire that comes to town every couple of months to work with a group of us. So it is not a problem for me now.

Getting weaker glasses

- *To:* i_see@indiana.edu
 - *Subject:* Getting weaker glasses
 - *From:* dennis@netcom.com (Dennis Yelle)
 - *Date:* Wed, 18 Dec 1996 11:50:11 -0800
 - *Sender:* owner-i_see@indiana.edu
-

Here are a couple of ideas that I have:

1. Go to a new doctor, take a pair of glasses, and tell the doctor that "I don't like these glasses, I think they are too strong."

No doctor likes to think that HE gave glasses that are too strong, but they have all seen patients who got glasses from some other doctor that are too strong.

2. Complain about headaches, especially when you wear your old glasses.

This is something that all eye doctors ask each time I have gone in. I didn't think that it was an important question so I always said no. But now I think that this is an important question to them. I think if you come in with an old pair of glasses and do not complain about "glasses too strong" or "headaches" or something, they assume that you need stronger glasses. If you complain about one of these things then they start off by thinking that maybe you need weaker glasses.

I recently found out that this is common with "regular doctors" and drugs. Often a regular doctor will start a patient with a small dose and tell the patient to come back in a month to "see how you are doing." If you go back and don't complain about anything, the doctor increases the dose. He keeps doing this until the patient complains about something that is on the list of side effects of the drug.

Your eyes are worth the prescription reduction.

>
> 2) Should I try to "convert" my optometrist, or drive two hours for a behavioral
> optometrist?

You don't really have to as long as (a) you feel you are doing something right (and you are) and (b) you get the reduced lenses. You can just tell the optometrist that you want a prescription that is lower, reflecting your need for less power, and is at the low end of the 20/20 range. Or if you want a small extra reduction, just say you need .5 or 1 (or fill in blank) less for the computer and for reading. If you want a large extra reduction, you'll have to explain what you are doing. People can sometimes tolerate the views of others (as in "this is just something I have to try", etc, etc) better when they don't feel your trying to convince them to change their basic beliefs.

But, if you need the optometrist's support (nothing wrong with that) then you may want to pursue a highly sympathetic one.

I'm just writing to indicate that there is a flexible range of options.

Here's a philosophical digression:

Someone posted a note a while back about marshalling your facts and being prepared to debate. That's important, but many people

will be utterly unconvinced, as you pointed out. People don't adopt a belief wholeheartedly based on reason alone. Reason only makes us think we're more in control of our incredible world. Some people feel seriously threatened when confronted with views that don't agree with their own, and they will go to great lengths including outright physical violence or emotional oppression to protect a rigid outlook. In the end, results convince. (I'm not intending to ridicule any individual or group, I'm just saying that one needs to be sensitive to inflexibility.)

I've used that one and it works. In my case, it's completely honest because I do get headaches when my eyes improve, yet I still wear the old glasses.

excellent suggestion. I've gone in not wearing glasses,
but keeping them with me, and they were used as a starting
point. Next time I'll just leave them in the car.

Hi everyone,

I guess I goofed in some of the references that I made earlier about Patching and Rayid method. Denny Johnson does not actually talk about the patching and astigmatism connection to the emotions discussed in his book What the Eye Reveals. Denny's book has pictures of the eye and describes the emotions in each area. The patching theory and astigmatism connection is from Dr. Kaplan and is in his book The Power Behind Your Eyes. Sorry Robert-Michael, you've done such great work in this area, I didn't mean to not acknowledge your efforts.

Another way to get the script you want is to find someone already wearing it. Most optical centers will "copy" a perscription and put it in one of their new frames, no questions asked! You could borrow the lenses, walk into the store and place your order, then walk back out and hand over the borrowed glasses. Be careful about astigmatic correction, etc. - but with a know perscription (the owner can call her eye doctor and ask) there should be no problem!

I only go to optometrists who have been educated by my vision improvement
teacher. I use the term educated as opposed to converted to emphasize that
change takes time and the cooperation of all parties involved.

You speak of the objective nature of your vision improvement i.e. change in
diopters of correction. What about the subjective changes? Do you feel that
your vision has changed significantly since you began vision therapy? Have
friends, colleagues and acquaintances remarked on any improvements in your
vision? Those changes are most important and you need no professional to
validate them.

When I started vision therapy I was having difficulty reading small print
and experiencing many headaches from computer use. Crossing a street
without my glasses was an adventure in anxiety. Now I wear 20/40 glasses at
work and rarely wear glasses outside the office.

I have far fewer headaches and have become much more aware of and nurturing

to my eyes.

It is a very brave and loving act to embark on vision improvement. Do not expect most people to appreciate it immediately.

I've never gone skydiving, but I suppose it would be good for the eyes.
The thought of jumping from a plane would increase my breathing capacity
considerably, and I think my eyes would become more alert and aware of the
surroundings :)

You're welcome! Once again, send "subscribe myopia-net" to
<Maiser@vision.eei.upmc.edu> All the big names in Myopia research are on
this list.

> What is the general consensus of the professionals on the list regarding the
> prevention and/or recovery of acquired myopia?

Why don't you join the list and ask them yourself? I tried myself once,
asking whether any of the members believed that myopia is genetically
determined, that is, whether environment, broadly construed, was not the
determining factor. I didn't get much of a response. I'd really like
somebody else to post and see what happens (they all know me too well). I
could write a commentary or summary of what they have said, but I'd rather
you get it from them straight.

As I said before, there have been about two postings to that list in the
past month (both by non-professionals asking what they can do about their
degenerative high myopia -- no responses were posted to the list). So
you don't have to worry about being deluged with mail if you subscribe.

Has anyone here tried bee pollen (or, is anyone familiar with it)? If so, have you any recommendations vis a vis brands/types?

Regarding the recent thread about Cell-Tech/Synergy, I just played the Synergy tape. As Cheryl had said, it was very interesting, and the documentation is reportedly a matter of public record. I might have dismissed it as hogwash were it not for a similar experience close to home. As some of you know, one of my relatives was brutally murdered and another critically injured in the Long Island Rail Road Massacre. Among other problems, Kevin's life was saved because he held up his hand to shield his face - but the bullet went through his hand, destroying the nerves, bone, et cetera. One very strange coincidence is that the neurosurgeon who operated on Kevin was trained by a neurosurgeon who now lives next door to a cousin in NC - and he told my cousin that, given Kevin's extraordinary strides, he should be able to eventually do everything ... that he'll learn to compensate for his loss and will be able to regain full use of his hand. I am obviously not explaining this well, at all, but my point is that the Synergy tapes do recount beliefs I've heard before (from prominent physicians).

Hi,

I do eat bee pollen on a regular basis. It's a complete food, very energizing, delicious, and not that expensive -- if you buy it from a local beekeeper! Get the phone number of a local beekeeper at your health food store, call them and ask to buy pollen in bulk. They will likely give you a big discount. Last time I got 7 pounds for \$20, I think. A much better deal than tablets. It's fresher that way, too.

Ari

Many thanks to Ari Solovyova <asolovyo@indiana.edu> and cheryl_lee@rdrorl.com for the posts about bee pollen.

Unfortunately, I don't think we have a whole lot of bee keepers here in New York City. However, I will see if I can find any in the suburbs ... seven pounds for twenty dollars sounds terrific, AND fresh.

In the interim, I will look of Montana brand in the health food store. As a vegetarian, I spend half my life in there, so it is disgraceful that I've missed this <g>.

Thanks again for your great help. I REALLY appreciate it.

Just in case I lose touch with you all due to the new mailing name, here's some information regarding the vision care product I was talking about.

The company name is Wan You Pte Ltd, based in Singapore, telephone +65 348 6742, fax +65 348 6741. Contact Mr. Khoo. If you fax your address to him he will send you a brochure. I've faxed my address and if the brochure is anything different from what I'll type below, I'll update you all.

Incidentally, if anyone goes ahead with this, I trust you'll let us all know the result. I only have my Singaporean colleague's stories about its effectiveness but she has told me great things about what it has done for her colleagues and family. I wonder if it is too good to be true since it seems to work quickly and easily and with only the cost being a possible issue.

Mr. Khoo says that the company is only in Singapore but that he has sent his machine to America before. It currently sells for Singapore \$488, which is approximately \$488 Australian dollars too (a lot of help, I know!), which is in the region of ?244. Sorry, I don't know about US\$. This is only a rough idea because of exchange rates, postage etc.

I have a fax which may be the brochure he was talking about. It lists a British patent number application of 9305156.3. Here's what it says...

"Eyes are windows of the heart. To have a pair of healthy and bright eyes is of lifelong importance of everyone. Yet with the acceleration of social development and pace of life, incidence of myopia has been increasing year by year, and so has the importance of eyecare.

The OO EYE EXERCISE DEVICE is designed to dissipate fatigue and to improve eyesight for people, especially youngsters, with myopia. Tens of thousand cases of clinical application has shown rate of effectiveness higher than 90%, many with slight myopia ridding themselves completely of their glasses.

DESCRIPTION

Based on the principle of human vision, the OO EYE EXERCISE DEVICE is a result of ingenious integration of modern electronics and optics with the "JING-LUO" theory of traditional Chinese medical science. It applies physically to the crystalline lenses and ciliary muscles and to various acupoints around the eyes, so as to facilitate the "CHANNELS" and improve circulation of blood and nourishment. It also makes the ciliary muscles do exercises of contracting and relaxing repeatedly, with a result of improving their ability to adapt themselves, thus restoring the eyesight to normality.

The OO EYE EXERCISE DEVICE produces an image which, driven by a miniature motor, moves slowly and periodically forward and backward. A cylinder with compound lenses, so designed as to eliminate chromatism, is directed at the image. When you look at this image through that cylinder, the constantly changing distance of the view will force your eyes to make constant adaptations, thus improving muscles. An ancient book on Chinese medicine singled out magnetism as the best thing to improve eyesight, saying that "with a magnetic pillow, one can keep his eyes sharp inspite of age". The OO EYE EXERCISE DEVICE has a specially-designed magnetic mechanism attached to the cylinder. This, with integrated electric, magnetic and optical therapies, it has achieved high efficacy and efficiency."

After that are the instructions for use, which basically say:

- test your eyes before you begin by putting the chart 5m away
- look through the eye piece for 5 minutes each eye (there's a timer)
- massage the eyes if the device has a massage attachment [hospital version only?]

My friend said that when they had a go in a demonstration the results were immediate (although probably not lasting?) after a 5 minute session and that that is what convinced them all to try this out.

More information:

"COURSE AND EFFECT OF TREATMENT

In case of myopia, astigmatism or amblyopia [my spell checker wants to change this to 'ambrosia!'], efficacy varies with your physique, age, stage of disease, etc. In general, efficacy is particularly high for youngsters with slight myopia, many of them ultimately ridding themselves of glasses.

Whether using big of small device, 5 days will be a course of treatment,

with 1-2 times a day, 5 minutes for each eye every time. Allow 1-2 days interval between courses. Be sure to record your eyesight after every course. Usually the improvement after the first course will be particularly significant. In 3-5 courses time you will have markedly improved and stable eyesight. 4-5 times a month thereafter will help to avoid relapse.

Those prone to read or write or work at the screen for long periods, eg computer operators, may use this device to dissipate fatigue of the eyes. It will prove an ideal health-care for anybody using computers.

Middle-agers may use this device to put of presbyopia."

That's all I have for now. They encourage feedback so they can help you improve more or they can improve their machine.

Someone tell me if it sounds reasonable!

Caroline

"Patients who came to Kaplan to be treated for eye problems often turned out to be more interested in deeper issues in their lives. Changes in home or career often accompanied improvements. Clinical results with documentation go far beyond the anecdotal. A double-blind trial conducted at Oregon's Pacific University College of Optometry found an average of 30 percent improvement in measured eyesight in a group of 44 people taking part in the programme.

Kaplan's own research suggest that structural alterations in the eye occur up to nine months after the perceptual changes, and is the subject of clinical trials of more than 30 North American optometrists. If confirmed, these findings could overturn vision therapies that treat the eyes as little more than simple cameras. In behavioural optometry, eye deformation is seen not as the root cause of visual defects but as the end result of misperceptions from the brain and mind."

Opening in the dark after steady adaptation to a large field of luminance 320 cd/m² (white light):

Time (Seconds)	Mean Pupil Diameter (mm)
0	2.9
1	3.5
3	4.7
5	5.6
9	6.4
60	7.3
180	7.6

so you can see that it can take a few minutes for your pupils to fully open, but they're most of the way open in less than 10 seconds.

Now the retina itself: From Modern Optical Engineering by Warren J. Smith, 1990, p.125

"When the illumination level is reduced, the pupil of the eye expands, admitting more light, and the retina becomes more sensitive (by switching from cone vision to rod vision and also by an electrochemical mechanism involving rhodopsin, the visual purple pigment). This process is called dark adaptation."

There is a chart showing the least amount of brightness you can detect after so many minutes in darkness. For when you look directly at something (foveal vision), after just 4 minutes or so you're as good as it gets. There are no rods in your fovea. But for your side vision (such as 10 degrees away from right where you're looking), where there are lots of rods, you keep getting better and better at seeing in the dark even 40 minutes later.

As I understand it, older people generally take longer to get dark adapted. One reason for this is that their pupils are smaller and stay small. I've often wondered how much of this is due to "that's how the human body works" versus "that's because of how they use their eyes." Maybe the eyes would behave differently had they regularly practiced sunning and palming (each changing pupils to opposite extremes to exercise and retain the full range.)

Now that you mention it, I do feel a little more introverted and shy when my glasses are off for the same reason: not being able to see their face. Only a small part of our communication is verbal. I'm much more likely to ignore people, or just watch people with my glasses off unless they are very close. This has plusses and minuses. It's easier when I'm with a friend who has better vision (corrected or uncorrected).

I just had an idea for an exercise to work on this issue: sit in a bustling place with glasses off and watch people, no matter how blurry they are; watch the spaces in between; relax; be quiet; don't attract too much attention (the goal is just to watch, not to interact). This might greatly increase one's ability to interpret non-verbal cues in that instantaneous/effortless/pre-thought mode that is so glorious to participate in by habituating one to the details (even though many of them will be blurry).

"The most recent study I have come across was published in a German medical journal concerned with therapeutic radiation and indicates that bee pollen may be quite helpful in reducing side effects. The article was published in 'Strahlentherapie' (Radiotherapy) (150, 5:500-506, 1975), written by P.Hernuss and colleagues, who are associated with several radiological clinics and universities in Germany. ... Ten of the patients served as a control group, receiving only radiation, while 15 others were also given 20 grams (about three-quarters of an ounce) of pollen three times a day throughout the duration of the radiotherapy. The authors note that the pollen came from France and was

=====

collected in pollen traps which removed the material from the rear legs of bees.

=====

A number of blood tests calculated to measure the various indices of general health revealed that the women who took the pollen were considerably better off. ... Compared to the women who did not receive the pollen, those who did experienced only half as much nausea, less than one-fifth as much poor appetite, half as many sleep disorders, less than half as much inflammation in the urinary and rectal areas, and just one-third as much worsening of general condition. 'The function and the mechanism of action of pollen is essentially unexplained up to the present,' the authors state (we had the article translated from the German), but also declare that 'In summary, a good tolerance and favorable influence of the pollen diet as adjuvant to radiotherapy in female genital carcinoma was found. ...' For physicians who may be interested, the source of the pollen was the company of E. Hagen, Freilassing, Federal Republic of Germany."

=====

This would indicate that bee pollen is pollen that bees collect on their rear legs that is then collected from the bees. -- ST

=====

The other reference I found is in Prevention magazine of January 1977, page 172, subject Bee Pollen Sensitivity, in the letters to the editor:

"The special properties of bee pollen have been recently widely advertised. Nowhere have I seen any word of caution to those hay fever and asthma sufferers who are sensitive to pollen. I would like to relate my experience.

"The first bee pollen tablet I took caused my throat to swell seriously--to the point that breathing and speech were impaired. Although I immediately took an antihistamine and five grams of vitamin C, the swelling did not subside for several hours. In fact, my throat was very sore and still somewhat swollen after 24 hours.

"I believe a word of caution is advisable to those persons with a history of pollen sensitivity. As a former hay fever sufferer (now well under control by strict adherence to a hypoglycemic diet), I must still be acutely sensitive to pollen and would like to save others discomfort and possible serious consequences.

"Elizabeth Beckett
"Durham, New Hampshire"

From: dtrudget@candelo.dpie.gov.au (Danny Trudgett)
Subject: Vision Improvement (re meditation)
Status: RO
X-Status:

G'day

I believe there are four major steps in myopia therapy. In order of importance:

- * Reduce eye strain
eg take regular eye breaks, use +ve lenses or weaker -ve lenses, etc
- * Relaxation
if stress (read muscle tension) is a contributor, then remove the cause
- * Diet
plenty of fresh fruit & veges, lots of vitamins (esp B group)
- * Re-learn
teach your eyes how to relax and see clearly in the distance

The first two are concerned with removing the cause. Good diet allows the body to function properly. Once the optimum (or at least improved) environment is created, then we can start to correct.

Meditation appears especially beneficial as relaxation technique (reversing the affects of cumulative stress). Also, during meditation there is no accomodative strain (or at least there shouldn't be). Add to this the power of positive suggestion via the mantra, and you have a pretty good method for correcting stress-induced myopia.

Worked for me, anyway (sans mantra). I improved 0.5 to 1 dipotre (from -2.5) over a 6 month period. Unfortunately, I lacked the discipline to stick at it and my eyes have regressed back to -2.75 <sigh>.

Such is life.

FYI

There is a place in India that teaches the 'relax and see' method (I don't actually know what the method involves, but it sounds pretty self descriptive). They treat myopia via diet & meditation. You must stay at the school full-time for at least one week.

THE SCHOOL FOR PERFECT EYESIGHT

From owner-i_see@indiana.edu Thu Apr 6 19:20:12 EST 1995
Date: Thu, 6 Apr 1995 19:11:54 -0500 (EST)
From: Alex Eulenberg <aeulenge@indiana.edu>
Subject: Emily Bates's Tips for Better Vision
Status: RO
X-Status:

Emily A. Bates, laboratory assistant and then wife of Dr. William H. Bates (author of "Better Eyesight Without Glasses") was herself a leading practitioner of the Bates method. I just discovered a book by her, called "Stories From the Clinic", written under her previous name of Lierman, published in 1925. It is an excellent collection of case studies and a description of the Bates method in practice (Margaret Darst Corbett's "Help Yourself to Better Sight" and Clara Hackett's "Relax and See" are two other great resources for applications of the classic Bates method. They are out of print -- check your library or used book store for them).

Here are some "suggestions" she gives (pp. 15-16)

* * *

1. If the vision of the patient is improved under the care of the doctor, and the patient neglects to practice when he leaves the office, what he is told to do at home, the treatment has been of no benefit whatever. The improved vision was only temporary. Faithful practice permanently improves the sight to normal.

2. If the patient conscientiously practices the methods, as advised by the doctor, his vision always improves. This applies to patients with errors of refraction, as well as organic diseases.

3. For cases of squint [turned eye] we find that the long swing is beneficial to adults and to children.

4. When a patient suffers with cataract, palming is usually the best method of treatment, and should be practiced many times every day.

[note for newcomers: Palming = covering the closed eyes with cupped hands, the fingers crossing on the forehead, so as to shut out all light -- the hands do not touch the eyelids!]

5. All patients with imperfect sight unconsciously stare, and should be reminded by those who are near to them to blink often. To stare is to strain. Strain is the cause of imperfect sight.

The following rules will be found helpful if faithfully observed:--

6. While sitting, do not look up without raising your chin. Always turn your head in the direction in which you look. Blink often.

7. Do not make an effort to see things more clearly. If you let your eyes alone, things will clear up by themselves.

8. Do not look at anything longer than a fraction of a second without shifting.

[Note: shifting = moving your point of visual attention, while observing the thing viewed to "move" in the opposite direction.]

9. While reading, do not think about your eyes, but let your mind and imagination rule.

10. When you are conscious of your eyes while looking at objects at any

time, it causes discomfort and lessens your vision

11. It is very important that you learn how to imagine stationary objects to be moving, without moving your head or your body [i.e. sub- or semi-conscious shifting]

12. Palming is a help, and I suggest that you palm for a few minutes many times during the day, at least ten times. At night just before retiring, it is well to palm for half an hour or longer.

* * *

Note the emphasis on EFFORTLESSNESS, SHIFTING, PALMING, and FORGETTING ABOUT YOUR EYES. These three principles are often neglected in modern interpretations of Bates. Modern methods of vision improvement usually go along the lines of "practice makes perfect". What the Bates method emphasizes is that there is a right way and a wrong way to practice. If you try to look at those blurry letters by staring or straining to see them, YOUR VISION WILL GET NO BETTER. Failing to take these principles seriously is what I believe is the source of most discouragement and skepticism of the Bates method.

Again I emphasize the importance of PROLONGED PALMING -- a half hour, preferably longer -- each day, and at smaller intervals throughout the day. If you think it's crazy and don't do it, you're missing out on a lot! During palming, it is helpful to visualize something pleasant. You must palm relaxedly -- we'll talk about how to do this later.

From: Alex Eulenberg <aeulenbe@indiana.edu>
Subject: Choosing your therapy glasses
Status: RO
X-Status:

On lessening myopia.

I've just been looking over some books by Jacob Raphaelson, published in the 50s and 60s, published by the "Research Foundation for the Prevention of Myopia, Inc." which, unfortunately, died with Raphaelson in the 60s. He presents an incontrovertible case against minus lenses and for plus lenses for myopes. Most of his advice is for children, for preventing myopia. He argues that if you just wear +1.00 reading glasses (available at any drugstore) for all prolonged near work, you won't go myopic.

My advice for moderate myopes (-3.00 to -5.00):

You want to give your eyes as much distance practice as possible: you want to "unbend" your eyes so they can see into the distance.

First of all, NEVER READ WITH MINUS LENSES ON! If this means you have to hold the paper four inches from your face in order to read it, so be it! If you hold the paper as far away as you can so that the letters are still good and legible, this will be equivalent to looking at the moon WITH your glasses on, as far as your focusing is concerned. Conversely, reading at a "comfortable" distance with your glasses on is like holding the paper even CLOSER to your face than the distance you would read it at without glasses, as far as focusing is concerned. Does this make sense? If it is

difficult to read, this is probably because it's hard to read while your eyes are so crossed. I suggest putting a patch over one eye as you read, alternating the patched eye at regular intervals. Always have your reading material as far away as possible.

Can you get around without your glasses? My advice is to get yourself used to walking around lensless. I am, with about 1 diopter of myopia, able to get around with +3.25 glasses on (the equivalent of a -4.25 myope without glasses). If you're really serious about this, I think you can make great progress in a week if you JUST DON'T WEAR YOUR GLASSES. Summer is a great time for this. Make sure you get a lot of walking done outside. Look at the treetops (but watch where you're going!) Close your eyes and let the sun shine on your face as you rock back and forth -- this does wonders!

At first, you might get eyestrain, because your brain/muscle system is learning new perceived distance/amount-of-focus ratios. Take it in stride, using your favorite relaxation technique (e.g. palming, swinging, neck massage, acupressure) when things start getting strenuous.

I've been doing some research on myopia reduction projects; in all of them the subjects are "undercorrected", which means they wear weak minus lenses during the course of the project. The results are kind of ho-hum. In all the best "improve your eyesight" books and articles (the ones with the best and quickest reported results) the advice is to discard your glasses as soon as possible. No halfway measures.

Every myope's first goal in vision improvement should be to learn to manage without glasses at all. Yes, it will be fatiguing at first, so choose a period of time where you won't be under a lot of extra stress. Maybe you want to experiment for one day a week, or a block of hours every day, and gradually increase. (Importantly, make sure you LOOK AROUND during this time!) If you drive, get yourself a pair of 20/40 glasses (the legal minimum for driving). Vic pointed out you may want to save your 20/20 glasses for night driving. Important: request a 100% spherical correction, which means no cylinder, no "astigmatism" correction. Get some cheap but sturdy frames and plain plastic lenses.

Summer is the perfect time to start going without glasses!

For low myopes:

It's no problem for you to get around without your prescription. Now go to the drugstore and get some +1.00 reading glasses. Wear them for extended periods of time, and always when you read or write. Or be bold and get some even higher power -- the more power you can tolerate, the more dramatic your improvement will be!

Subject: Tips for the Nearsighted
Status: RO
X-Status:

The best way to improve nearsighted eyes is... take your glasses off and get used to it! You will notice an amazing improvement in your glasses free vision if you can do this for a week, especially if you spend lots

of time outside.

This is not enough to bring you to 20/20, but it is a start. The most important thing is to practice looking at the details of familiar, distant objects. They should be familiar, because you don't want to waste brain energy trying to interpret what you're looking at, when you should be re-training your brain to focus for far. The trick is to see the point that you are looking at best. Strain results from trying to see everything all at once equally well. So imagine that whatever you are looking at is perfectly clear, sharp, and distinct, while everything peripheral is correspondingly indistinct. This will also force your eye to shift more frequently; less staring = less eyestrain.

It is true that high myopia is caused by an eyeball that is inherently too long, but myopia also results from a focusing muscle that cannot relax. Relaxation of that muscle brings about a reduction in nearsightedness. Many believe that it is actually the over-contraction that leads to the eyeball elongation in the first place.

Please check out

http://silver.ucs.indiana.edu/~aeulenbe/i_see.html

for more information on this subject, including bibliographies. There are lots of books still in print, and many more available at the library!

> muscle cause it to return to normal shape?
>

An normal eye can become nearsighted by (a) making the lens more convex, or (b) elongating the eye (increasing the distance between the lens and the retina).

According to the standard theory of accommodation (i.e. how the eye focuses, or "accommodates" to see objects at different distances) the eyeball does not change shape when the eye changes focus. Instead, the ciliary muscles cause the lens, which is inside the eye, behind the pupil, to change shape. When the muscles contract, the lens becomes more convex for near objects, and when it relaxes, the lens becomes less convex for distant objects.

Now if the muscles that control the lens become cramped, and unable to relax, then the lens will become perpetually more convex than it should be for distance viewing. This is known as "pseudomyopia". It can be cured by relaxing the ciliary muscles.

It is thought that pseudomyopia, or too much close focusing, for one reason or another, causes the eye to elongate, either by the action of the lens, or by an increase in internal pressure during close-focusing. This

is a poorly studied area, but there are experiments to support this contention (see Myopia Control bibliography at the I_SEE page).

Many people have their eye-elongation myopia compounded with muscle-cramp myopia, as evidenced by the fact that their prescription plummeted after a month or two of wearing no glasses, or glasses of a weaker prescription, and in that time, making it a habit to look at the details of distant objects.

I add here that it has been theorized, and there is evidence for the idea, that, in addition to changes in the lens, the eye actually DOES change length during accommodation, primarily under the influence of the muscles OUTSIDE the eye. This makes the connection between excessive close focusing and increased eye length much easier to understand. Permanent myopia then, is the result of an over-stretched eye. No optometrist or ophthalmologist that I know of today believes this theory of accommodation; however, I have uploaded experiments that give evidence for the theory on the I_SEE page, that are about 200 years old...

Hi,

people were wondering about palming - I don't have an answer to offer, but a speculation. (maybe even an interesting speculation)

I'm a student of Qi gong and East Asian Traditional 'Medicine'. These disciplines rely amongst other things on qi channels and points on those channels which are used, besides other things, in acupuncture treatment. In many forms of 'medical' qi gong a point in the center of the hand is used in a therapeutic manner. Qi gong therapist will use the center of their palm to manipulate the qi in the patient, and of course this can be done with one's own hand, to a degree.

While some fraction of the scientific community supports these things, others are very sceptical. I can only speak from experience - that point in the center of the palm can have **strong** effects on measurable aspects of physiology.

A manipulation very similar to palming is in fact part of a traditional eye-massage in some schools of Oriental Medicine.

Maybe this explains part of the secret to palming, and maybe not.

margot

btw: In Qi gong, the hand is also placed on other important areas of the body for various effects in improving health balance, meditation, and the like.

> logic tells me I should be exercising my eyes to improve my vision.
> Otherwise why don't I see better after a night's sleep?

These are three very good questions that many people have.

I answer:

Palming does more than rest the eyes. Leaving aside the question of the life energy force ("chi" in Chinese, "prana" in Sanskrit, "orgone" according to Wilhelm Reich) coursing through the hands and into the eyes, we note...

1. The eyes are warmed by the hands
2. The muscles around the eye are gently massaged by the pulse from the

hands.

3. All light (= retinal stimulation) is excluded, whereas when you sleep, some light may shine in through the window, especially in the morning.

In comparison with sleep, we note that bad habits of tension may creep back into the eyes during dreaming. And everybody does dream, whether or not they can remember their dreams. Often dreams are confusing and muddy, straining your eyes. When you palm, you are conscious, and have more control over your thoughts.

As for exercise, yes exercise is important, but remember, exercise is ineffective as long as the organs being exercise are under strain. It's not true that practice makes perfect. Only PERFECT practice makes perfect. You cannot exercise perfectly unless your eyes are free of tension.

Another thing: you can exercise your vision while palming, by shifting and swinging pleasant images in your mind.

I like to do it lying down. you cover your closed eyes with the cupped palms of your hands, with the fingers crossing over your forehead above your nose. it should be pitch black. do *not* touch you eyes with the hands. then you can either do visualisation, if your are into that. or just sit/lay back and meditate.

when you stop things are clearer and your eyes feel warm and much more relaxed and free of tension.

Status: RO
X-Status:

There haven't been many how-to-improve-your-vision posts lately, so here's one.

Very simple. First take a look around and take a note of which things are clear and which things are blurry.

Now, put your hands over your eyes for a half an hour. Do not put pressure on your eyeballs. You may blink or close your eyes, just do not let any light in. The fingers of your left hand should cross the fingers of your right hand on the middle of your forehead. If it helps you relax, listen to your favorite music or radio show. Be open to any visual images that may cross your mind. You may lie on your back or sit in a chair or on the floor, whatever is most comfortable. Don't slouch though. You might want to prop up your elbows with a cushion.

After the show's over, or the tape has come to a stop, or your 30-minute timer has buzzed, take a look around. How do your eyes feel? How do things look?

Variation: wear a patch over one eye for a half an hour.

Yes, darkness does amazing things for the eyes.

Let I_SEE now how palming works for you!

X-Status:

Alex,

I've been working to improve my eyesight for a while now, and I have some observations regarding palming which I thought you might find interesting:

- When palming do not set a time limit, try to forget about time. This is because time is measured by the left side of your brain, vision is handled by the right side of the brain which is the side that should be stimulated by palming. This is why you are encouraged to think about images during palming as again this stimulates the right side of the brain. The amount of time spent palming should be the amount of time that you feel comfortable and relaxed when doing it - do not PUSH yourself to go an extra 10 mins as this will probably stress you out and undo some of the good you just achieved.

- I find listening to music is great during palming, however it must be music with no one singing, just music. Again this is because language is handled by the left side of the brain, and so if you listen to the words, the left side of the brain is taking over your conscious thought. (Have you ever noticed when you've drifted off listening to music and you no longer hear the words just the tune, well this is because your left brain has switched off and has handed over to your more thoughtful and creative right brain which has carried you off to a world full of images and dreams).

Anyway, I have generally found that a lot of left/right brain theory is relevant to eye work, and has many other implications as well, all of which is fascinating to explore :-)

Hope you found this relevant.

Regards,

JP.

I interpret your question/statement to be that the iris closes, becomes smaller in the dark, that it is like a pinhole camera. Pardon me if I've read it wrong, but the iris opens in the dark, takes on a larger aperture. So I question the analogy.

FOr me, palming provides an opportunity for a relaxation response. I can feel my eyes relax, my mind relax, and general relaxation. It is easy for me to unconsciously strain to see and palming helps to counter act that. Medical science is beginning to accept the detrimental effects of long term stress and I think this is all related.

Brad

William Bates, author of "Better Eyesight Without Glasses", said that such patterns are evidence of eyestrain. Those with "perfect eyes" see a field of pure black, whereas those with "defective vision" see colors or a field of gray; the more wild the patterns, and the less black the field, the higher the strain. He did not give any physical

explanation for this.

However, I have noticed that, for me, while I usually see gray-black myself when I close my eyes, after a period of intense "aerobic" activity, such as swimming, I will often attain a purer black when I close my eyes, which coincides with an improvement in vision when my eyes are open. I have concluded that this effect, and what Bates observed, has something to do with blood flow through the eyes, in particular the retina.

>Is there a unit of measure for eye-brain light
>perception in total darkness? Can this be an indicator
>of any kind of eye disease?

Bates said that the more excited the pattern, the more defective the vision. He did not give any units. Details can be found in his book, which is still in print. Incidentally, he considered any amount of myopia or astigmatism defects due to "mental strain". He said the higher the "strain" and thus the higher the error of refraction, the less black the visual field will be with no light stimulus.

It would be interesting if someone could verify the correlation that Bates made. For example, do high myopes see wilder images when they close their eyes than do low myopes?

For example, my myopia last measured in at about -1.00 OU, and all I ever see with my eyes closed is patches of gray or dull clouds of purple. No flashes.

One vision therapy exercise that has totally eliminated my sensitivity to sunlight (blinding glare off of metal, glass, etc. notwithstanding) is "sunning." It's basically closing your eyes and pointing your face toward the sun. If you are very light sensitive you may want to start by closing your eyes and just facing into the sky but not directly at the sun. NOTE: At no time are you to open your eyes while looking at the sun!! This stimulates the rods and cones in your eye. Anytime I come out of a very dark place, like a movie theatre, I do this exercise for about 20 seconds, and have no problem. I do not wear sunglasses anymore on a regular basis. I keep them handy for glare situations and only then when I'm wearing contact lenses which is not very often anymore....

Forgive me if I'm wrong, but sunning is to be done with the eyes closed. The way I was taught is that you swing while looking at the sun. therefore, the sun isn't fixed in any one place on the retina, or the eyelids, and besides, it just plain feels good, and relaxes me.

In my estimation, relaxation is better than worrying about a thing. Like some people worry about their diets and what they can and cannot eat. this kind of strictness causes stress. Stress causes bodily injury. In some cases it would be less injurious if they just ate the food, instead of worrying about it.

Most of us live in artificial environments which gives us limitation of exposure to full spectrum radiation, then some go on holidays and are 'gluttons for the sun'. Perhaps it would be better if we took in a little each day. What did we do before the electric light bulb and artificial environments?

It seems a sad day to be afraid/worried about the light which gave us life. (the sun).

Subject: the sun and the eyes
Status: RO
X-Status:

Solar retinopathy is characterized by a small circumscribed hole or cyst that develops 2 weeks after exposure to the sun. The lesion is thought to be caused by phototoxicity rather than by thermal effects. Vision as poor as 6/60 typically results due the central location of the lesion. There is evidence for some contributory effects of infra-red radiation rather than simply an excessive exposure of visible light. There is little if any effect of UV light in this condition, as the cornea and crystalline lens are effective filters.

Basically, too much light burns a hole in the retina, leaving the idiot who looked at the sun centrally blind. This is most common during solar eclipses, when people try to catch a glimpse. In other words, even 10% of the sun is far too much!

Acute, excessive UV exposure will lead to corneal damage (solar keratitis), which is basically sunburn of the external eye, and chronic UV exposure is associated with brunescant cataracts and possibly with age-related macular degeneration, the leading cause of non-treatable blindness in the elderly.

There is an old joke about sunning the eyes as a treatment for myopia. If you stare at the sun, you will end up seeing as well without glasses as with glasses. But only because you have made yourself centrally blind.

Well, one may argue about whether 'sunning' will improve vision, but it is clear that Ultra-Violet Radiation is harmful not only to eyes in particular, but life in general. Notice that I didn't say 'sunlight', but 'UV Radiation,' which is more specific. Sunlight contains UV Radiation, some of which reaches the ground -- more now that the ozone layer is depleted. Thus the common recommendation to wear sunglasses and sunscreen.

I think that there is much confusion about whether sun exposure is 'good' or 'bad' for you because people don't realize that different parts of the Electromagnetic Spectrum have different effects on us. The UV part of the spectrum has harmful effects -- on eyes and skin -- but the visible part of the spectrum seems to have positive effects on general health (as it helps the body produce vitamin D and who knows what else) and may have positive effects on eyes, though I'm personally unaware of the evidence for that. Anybody here know what it is?

> Well, one may argue about whether 'sunning' will improve vision,
>but it is clear that Ultra-Violet Radiation is harmful not only to
>eyes in particular, but life in general.

not quite true. there is WHO report which shows that UV is only dangerous
for people with a diet high in animal fats. Vitamin D is produced
in humans from one of the UVs. Plants will not grow as
well if deprived of UV. females dont produce as much sex hormone
if deprived of UV. etc etc.

I have read about the experiments that proved UV is dangerous.
monkeys had there eyes strapped open and 2500W UV lamps were used
to flood the eyes for days on end. and surprise surprise they found damage.

>Notice that I didn't say
>'sunlight', but 'UV Radiation,' which is more specific. Sunlight
>_contains_ UV Radiation, some of which reaches the ground -- more now
>that the ozone layer is depleted. Thus the common recommendation to
>wear sunglasses and sunscreen.

The lens of the eye filters out UV. so sunglasses are a bit
redundant. if you do sunning you do it with your eyes
closed. so very little UV even gets to the lens. unlike bees

we dont see UV. the FAQ advocates not wearing sunglasses if you have any sort of light sensitivity. once you have eliminated this sensitivity then you can start wearing them again, but only in a a fashion which will not reintroduce the sensitivity. most people wear sunnies as a fashion item, not out of concern for UV.

> I think that there is much confusion about whether sun exposure is >'good' or 'bad' for you because people don't realize that different >parts of the Electromagnetic Spectrum have different effects on us. >The UV part of the spectrum has harmful effects -- on eyes and skin -- >but the visible part of the spectrum seems to have positive effects on >general health (as it helps the body produce vitamin D and who knows >what else) and may have positive effects on eyes, thought I'm >personally unaware of the evidence for that. Anybody here know what >it is?

not quite true. some UV is beneficial. 4 billions years of evolution has not created a human being which withers and dies in open full spectrun sunlight.

my feeling is for the purpose of correcting visual problems the small amount of exposure seems to do nothing but good.

> BTW, this is a response to something I think Vic said: The ozone >_hole_ is actually over the polar regions, if I remember correctly.

the hole actualy goes right over my head during summer I believe.

>Nevertheless, your conclusion that people near the equator (and at >high altitudes) are at higher risk is correct because 1) there is >global ozone depletion, and 2) the sun's rays are more direct in >equatorial regions. Peace...

true.

Vic

Uh, what's the definition of 'dangerous' here? I suspect that the WHO study used as less strict definition than the one I implied. Nothing wrong with that, as long as we know it. See cements below about UV's effects on proteins.

> Vitamin D is produced
> in humans from one of the UVs. Plants will not grow as

Ah, but which one? UV-A, in light doses, might help you make Vitamin D, but a strong dose of UV-C might (probably would) kill you. These differences are important. ;)

> well if deprived of UV. females dont produce as much sex hormone
> if deprived of UV. etc etc.

> Hadn't heard this last one. By all means, put the women in the sun! (sorry...)

> I have read about the experiments that proved UV is dangerous.

> to flood the eyes for days on end. and surprise surprise they found damage.

Surprise indeed; I hadn't heard of these 'experiments.' Didn't the ASPCA have something to say about them?

I was basing my comments on the more basic observation that UV (especially UV-B, ~300 nm, I think) breaks down animal proteins.

> The lens of the eye filters out UV. so sunglasses are a bit

Really? With no damage even to the lens itself? This surprises me...

> not quite true. some UV is beneficial. 4 billions years of
> evolution has not created a human being which withers and dies
> in open full spectrun sunlight.

Uh, 4 billion years of evolution first created on Oxygen atmosphere, then an Ozone layer on top of it, which almost completely filters out the 300 nm radiation, before life like us crawled out of the ocean.

UV radiation -- and especially that in the ~300 nm band -- breaks apart the proteins that are one of the 'building blocks' of organic, cellular life like us. It wasn't until the Ozone layer blocked most of this radiation from reaching the surface of the Earth that life really got going -- though it was a form of life that excreted oxygen (by metabolizing CO2 and probably other things) that created our oxygen atmosphere in the first place. I believe that this life was mostly green (i.e., it contained chlorophyll), in the ocean and possibly on land.

> > BTW, this is a response to something I think Vic said: The ozone
> >_hole_ is actually over the polar regions, if I remember correctly.

> the hole actualy goes right over my head during summer I believe.

I think you're correct. You live in Australia, right? The ozone hole is over the south pole, and in summer for you (winter for us in the Northern Hemisphere) it does get large enough to be over Australia. Thus you are getting completely unshielded exposure to the 300 nm radiation that is most harmful to life.

Australia has higher skin cancer rates than the rest of the world, doesn't it? That's why. Denver also has higher skin cancer rates than the rest of the US (so I'm told, can't give you any refs.);

the reason given is that it is at a higher altitude, and thus receives less filtered sunlight.

I think an underlying assumption here is that something is either a boon or a bane, but not both. I think that's probably wrong. Sunlight certainly has many beneficial effects, but it also has some harmful ones. Knowing this, the question isn't 'to sun or not to sun,' but rather, 'how much sun exposure will give the appropriate balance between the beneficial and the harmful effects of sunlight, and what can we do to preserve the beneficial effects but minimize the harmful effects?'

This is clearly a question that each person must answer for him/herself.

What I really wanted to get at is the claim that one can simultaneously decrease light sensitivity and increase nightvision. Is this the claim? If so, regardless of the technique, how is it possible? It seems to me that the two things would be mutually exclusive; if you see well at night, you're sensitive to sunlight.

I've always tried to wear shades, partially to protect from UV-B, but also to maintain light sensitivity, so that I'd also maintain good nightvision, as I find the latter more important. So how is that that my eyes might be capable of both good nightvision and low light sensitivity? Peace...

Subject: Reducing nearsightedness with reading glasses
Status: RO
X-Status:

Here is the easiest, most common-sense way I know to reduce nearsightedness.

First, get a hold of a pair of reading glasses (available at the drugstore for \$10-\$20). The power doesn't matter as long as the point when blur sets in is a comfortable reading distance away.

Now, take something to look at: a picture, some reading material -- anything really, and hold it just at the point where things just start to get blurry. Now relaxedly scan the image. Look at each detail, point by point, breathing calmly and blinking regularly -- don't stare. The image should get clearer. Now push the image back and repeat. If you are able to do this while reading a book, great. But if you'd rather look at photos or an art book, that works just as well. If you can't get the image into focus, don't try harder; just pull in a little bit till it gets clear and then pull out again until the image is just barely blurry again. You are training your focusing muscle to relax (the muscle contracts to see things up close), so you must avoid anything that would cause stress and therefore contraction!

Variation 1: do it with a patch (\$3-4 at the drugstore or optometrist). Advisable whether or not both eyes are equally nearsighted, for three reasons:

- 1) it avoids the strain involved when two eyes must coordinate; plus,
- 2) it allows one eye to rest (pupil dilates = iris is relaxed; no light stimulus getting on your retinal nerves)
- 3) it ensures that one eye is indeed training, and not letting the other one do the work.

Variation 2: Zooming. Take two playing cards, back patterns facing you, push one out into the blur while you keep the other one within focal range. Shift your gaze back and forth, comparing the images of the two cards. Move the cards back and forth. Be creative!

If any I_SEE'ers can come up with a new variation, be sure to post it!

From: Alex Eulenberg <aeulenbe@indiana.edu>
Subject: "But I simply MUST read!"
Status: RO
X-Status:

The first principle of myopia reduction is: maximize the proportion of time you spend distance-viewing. Since distance lenses (minus lenses) bring everything up close to you, this means getting rid of your myopia prescription lenses. Remember, when you look at the moon with as low as a -1.00D prescription, as far as you eye is concerned, you're only looking a meter away. So by all means you should NEVER READ WITH DISTANCE LENSES ON!

Still, reading even without minus glasses is near work, the very near work that put you behind glasses in the first place! What should you do

if you simply must read, and you can't stand having to "palm" at every page, and you don't have a window to look out of?

1. If your myopia is high enough, you can hold a book (or sit comfortably away from your computer screen) at your far-point. This will be enough to start pulling your eyes back into shape.
2. If and when your myopia is low enough such that it is inconvenient to read at the blur point, you will need some special equipment...

...reading glasses! You can purchase them at the drugstore for under US\$20, and you don't need a prescription. Just walk into the drugstore and put a pair on and look at something at a comfortable reading distance. You'll probably find that the lowest available power (+1.00 or +1.25) is the best. Now you can read and look into the distance simultaneously! To find out where the "virtual moon" is, take the reciprocal of the lens power and read the result in meters. Thus, for a +1.25 lens, that's $1/1.25$ m, or 0.80 m -- whenever you look at something 80 cm away in +1.25 lenses, as far as your eye is concerned, you're looking at the moon!

And while you're at the drugstore, why not pick up an eye patch? No sense looking at a 2D page with 3D vision. Not only do you use twice the retinal forces that you need, you waste valuable brain energy keeping your eyes coordinated. You can keep your eyes super fresh and strain-free while reading by wearing a patch over one eye and looking through a plus lens with the other. Alternate eyes at regular intervals.

For the first time in your life, your distance vision will be BETTER after prolonged reading!

>

> For the first time in your life, your distance vision will be BETTER after
> prolonged reading!

>

I found that the most effective way to force my eyes to focus beyond my blur point is by reading one same word over and over. I really worked in that after 1-2 minutes of reading the word, I could trace the edges of the letters that form the word. I usually do this every three/four pages of reading materials (ie. read four pages AT/JUST BEFORE the blur point, focus on one word slightly BEYOND the blur point).

Do you guys think that this could accelerate/inhibit my eye training?

Another thing that I notice is that I am becoming more conscious about having to focus my eyes at something near. The other day I was helping my wife to fix a piece of jewelry, and I realized that I was focusing to a near object (+/- 5 cm) w/ my glasses on!!!). Ouch, that hurt. This is the kind of thing that used to make my eyes more and more myopic (not anymore. my vision training have held my prescription constant since my junior high).

If any of you are having progressive myopia, watchout for this kind of thing, and try to avoid it.

Andy

ps: Vic, what's the status of your bet w/ that doctor from SMV?

X-Status:

Hello again,

Thanks for responding to my post so soon. I already had the appointment with Dr. Westgate about two weeks ago. He said that he hadn't heard of VF or Mr. Severson. While I was there I just paraphrased the 60 page booklet I'd received in the mail to Dr. Westgate. He was familiar with the technique of accomodation to improve vision but said there weren't many studies on it's success and that in my case(-4.25 Left, -4.00 Right) there wouldn't be much improvement.

I didn't get the impression that he was trying to mislead me or anything. From his experience and reading he just hadn't seen data pointing to vision improvement for anyone using accomodation or biofeedback procedures.

I have to share a bit of my history to you:

I've been under the care of Dr. Joel Halpern O.D. while going through orthokeratology for the past four years. Initially my acuity was in the 20/400 range for both eyes. After about seven months of the OrthoK I could see the 20/30 line on an eye chart with my right eye...20/50 with my left immediately after removing the lenses.

Unfortunately, the effect doesn't last very long(eight hours max) and now the best I can see when I take the Ortho lenses out is 20/70R 20/100L. I am a pilot and college student studying Airway Science. My goal is to fly for a major airline but I'd rather fly for the Air Force. I could pass a Class I physical needed for the airlines as I am now.

My hope was through, vision therapy, of increasing my acuity to the point of passing the Air Force vision test. From reading Mr. Severson's booklet this goal doesn't seem out of reach. If I could make drastic improvement with my acuity to say 20/60 in each eye with vision therapy or more specifically Vision Freedom I could get down to 20/20 using Orthokeratology.

Why am I sharing all this? Dr. Halpern has helped me a lot and I don't want to lose his support. I originally asked him about the VF booklet and he then set up an appointment for me with Dr. Westgate to see if he knew anything about it and if it would benefit me. They operate under the same practice, Halpern Eye Associates. As I stated earlier Dr. Westgate's news was not what I wanted to hear but I think he was being honest with me. With my next office visit with Dr. Halpern he told me about a seminar he'd just been to concerning the excimer laser and it's use for PK and how a U.S. firm is refering patients to Canada for treatment.

Here's my dilemma. PK would disqualify me for an Air Force commision as would any other surgical technique to modify the refractive power of the cornea.

I'd like to go the Vision Therapy route but my doctor doesn't have any data concerning significant improvement for myopes or anyone else. While undergoing OrthoK I can't effectively use the techniques outlined by Brian

Severson. Dr. Halpern told me that he would be more than happy to help me in any way he could but he'd need evidence of vision improvements in other patients, data, or something to those effects in order to justify the suspension of my OrthoK treatment at this point.

Could you send me, Dr. Wesgate, or Dr. Halpern any information on other doctors who use plus lense therapy or the book titles you listed in your last message. I'd really appreciate it.

--ps I the Prodigy Browser to get the FAQ at <http://silver.ucs.indiana.edu/~aeulenbe/> but it wouldn't accept the address. Is there another way to get it?

Thanks for your time

You mean your myopia is so high that you cannot read at all without glasses?

This is a very worthwhile question that leads to another question of mine. When I read without glasses, I must hold the paper 6 inches from my face. Also, I feel eye strain when I read thusly. My questions are:

1. Should I read without glasses anyway?
2. Is the eyestrain I feel temporary due to the transition from glasses to no glasses, or does it indicate that I need training in reading properly without glasses?

I have often thought that it would be a good exercise to read without glasses, and that over time I would notice that I can hold the paper further from my face. I have resisted this impulse because I was concerned that due to problems I am not aware of, I may make things worse. This was probably an illusion on my part. I should probably just do it and see what happens.

Mark

From: Alex Eulenberg <aeulenbe@indiana.edu>
Subject: Vision Freedom secret revealed
Status: RO
X-Status:

I_SEE member Mark Jensen asks about Brian Severson's "Vision Freedom" method for reversing vision defects. Does it work? Yes. Is it worth shelling out \$100 for? No! Here's the secret...

The technique for myopia consists of reading some text at farther and farther distances. This is only common sense. The problem is, most people's arms (or keyboard cords) aren't long enough to make this

practical. So you wear reading glasses -- glasses for people who need the text to be pushed back in order to read it -- which accomplish the same thing optically. This technique is over a hundred years old, incidentally -- I've read about it in several books by eye doctors of yesteryear -- (Chalmers Prentice and Joseph Raphaelson). Now you can send Brian Severson \$100 for these glasses, or you can go to the drugstore and buy them for \$10-15. Your choice. If your myopia is severe enough, you can practice bare-eyed.

Now for people with near-vision problems, I don't see what you need extra glasses for. Using whatever prescription you now have, just bring the text closer and closer until you are able to take your reading glasses off and continue. Of course, if you're just starting to lose your near vision, you can start practicing without glasses.

In general, you're supposed to hold the text at the farthest point where it's still readable -- that is, just barely blurry. In a matter of minutes, if you read relaxedly and breath calmly, the text should clear up and you move the reading material in the desired direction.

This technique works well in conjunction with the shifting and palming techniques of the Bates method.

Shifting: As your eyes go right across the words and letters, the words and letters (or parts of letters) go left, and so on. Observe the contrary motion of the visual image as your eyes pass over it.

Palming: It may happen that the text gets more blurry instead of less. At this point, you must stop, cover your eyes, and imagine something pleasant -- often a crisp black letter on a snow-white page helps, but it can be anything of any color, as long as it's easy for you to visualize. Then open your eyes and go at it again.

And what you're reading should be something enjoyable. If you have to struggle with the content, the mental strain will hinder improvement.

I have used this technique with great benefit. It especially helps to cover one eye with a patch while doing this, and alternate eyes at regular intervals, say, every ten minutes, or train a different eye each day. What I find is that the effect wears away if you don't keep at it. As for me, I was able to bring myself to 20/20 from 20/50 with the glasses/patch method in about a week, then I got lazy and now my vision has slipped back to about 20/30.

To be effective, this technique requires that you spend at least a half hour at it each day, the longer the better. If you can do it several times throughout the day, so much the better.

hi

I have just got my first pair of reading glasses. simply getting them was a bit of a comedy.

me: "Id like a pair of reading glasses"

lady: "oh no you need to go to an optometrist to get a prescription"

me: "no no, I want a pair of +1 glasses I dont need a script for that".

lady: "no I dont think you now what you want".

me: "yes I do know what I want, can I please have a pair of +1 reading glasses".
etc..

anyway she only had +1.5 and after a bit of convincing that I wasnt crazy took them home.

I put them on and eek. yuk. makes everything look more myopic then without them. Not one to shy away from any experiment, I left them on for a while. surprise surprise after the inital headache and total inability to make out anything more then the big E on my eye chart, letters slowly started comming out of the increased blur! so I tried reading. eek! had to hold to book quite a bit closer then normal. and again after maybe 20 minutes I could start moving it away again.

so clearly my eyes were able to compensate for the extra +1.5 by becoming more -ve, in other words less myopic!! this is a very intresting phenomena, just where do the eyes find room to change maybe .5d in a matter of maybe half an hour?

Of course when I finally took them off I could read more of my eye chart. I put on my -1.25 compensating (normal) glasses which were prescribed to give around 20/40 and I was reading the 20/20 line with ease and bits of the line underneath! the effect didnt last too long but obviously with daily usage it would become more and more permanent.

so the answer to your question is your eyes will adjust to the glasses and become less myopic. keep reading matter at the border line of visibility and beyond to get a good effect. give yourself frequent rest as well.

Vic

From owner-i_see@indiana.edu Sun May 28 11:57:54 EST 1995

Subject: Case study: improvement with plus lenses
Status: RO
X-Status:

This report was published by Chalmers Prentice, M.D., in his book "The Eye In Its Relation to Health"

Age forty-three; myopia; had been wearing over the right eye -1.25 D, left eye -1 D, with little or no change for the space of two years; eyes in use more or less at the near point. I recommended the removal of the concave glasses for distant vision and prescribed +3.50 D for reading, writing and other office work. After reading in these glasses for several days, the patient was able to read print twelve inches from the eyes. This patient was of more than ordinary intelligence and understood the aim of the effort. In six months I changed the glasses for reading and writing to a +4 D without seeing the patient. After using the +4D glasses for several months he again came under my care for an examination, when the left eye gave twenty-twentieths of vision, while the right eye was very nearly the same, but the acuity was just perceptibly less. During this time the general health had improved somewhat, including considerable gain in the nervous condition. Similar results have been attained in thirty-four like cases; but the process is very tedious for the patients, and unless their understanding is clear on the subject, it is almost impossible to induce them to undergo the trial.

Note that glasses this strong (+4) can often not be purchased without a prescription. However, one can wear one pair of glasses over another for an additive effect!

> myopic.

Marco:

> There is a point that you might be missing. From the above statement it seems
> that you are trading wearing - lenses for + lenses. Glasses are glasses. I
> thought the whole point was to get rid of them.....

The point isn't so much to get rid of glasses as to eliminate the need for glasses in order to see clearly.

For the near-sighted, plus lenses are a therapy to unbend the eyes, and let them see far. For those with normal eyes, wearing plus lenses while doing prolonged work prevents the over-bending of the eyes which creates near-sightedness. Raphaelson observed that continual use of plus lenses did not lessen one's ability to see up close -- except in the aged (presbyopic): "It is only some of the aged and those who have very poor eyes who get accustomed to plus glasses and become unable to see clearly without them." (from A preventive and remedy for school myopia, p. 59)

If one wears plus lenses for all extended near work, Chalmers Prentice (1895 -- The Eye in its Relation to Health) notes, "the nerve-impulses to the ciliary muscle will be no more than if the patient were leading an outdoor life and viewing objects at twenty feet or more. The nerve-centers are not called upon for so excessive an

impulse, and they become habituated to sending the same amount of nerve-force as if an outdoor life were led.... Under these artificial conditions, the eyes may be used in the attainment of all the advantages of the highest civilization while the nerve-centers are no more taxed than if out of door pursuits were being followed."

As for developing near vision...

"...on leaving the school room they could be taken off and the natural use of the eye at all other times would be quite sufficient to cultivate and establish the habit of accommodation [focusing at the near point]" (ibid)

Alex replies:

For preventing myopia, your plan might work. However, I think once every twenty minutes is not often enough. Also, if you're reading without glasses, the best thing to do would be to have a distant scene in back of the book so that you can constantly be focusing back and forth, say, between a faraway tree and the page.

But just remember: with "plus" lenses you've got EXPANDED focal opportunities, unlike with "minus" lenses which lock you into a DIMINISHED focal playground. With a +1.00 lens, one meter gives you, optically, a world of focal practice. It takes nothing away; in fact it gives you the opportunity to try to see "beyond infinity" when you look at anything beyond a meter. If you want a little near-practice, you can always bring

the book clear up to your nose. Whereas with a -1.00, it is impossible to look at anything that demands more than a meter's worth of focus.

No! Just taking your glasses off will be plenty! Perhaps too much. You're going to have to bring down your prescription in steps -- something an eye doctor will have to help you with, since minus lenses are not available without a prescription.

Once again, if you want the name and number of a behavioral optometrist in your area, send me a message!

Marco Counters:

Alex, I certainly respect your opinion and I know you are well read in the area, but I do not entirely agree with you in one little point: 20 minutes *IS* enough for some people (yours truly included). Then

again I am a low myope. Something that I have noticed: As a myope I notice that when I read I tend to get my head closer to the screen/book even though I can read from a farther distance. Something that I am trying to do is retrain myself to read stuff from 'close' to the blur point. Just my \$.02

Cheers!

Marco.

you have to make the distinction between plus lenses and minus lenses for myopes. minus lenses are forever. plus lenses are short term. once you compensate for the eye focus short with minus lenses (ie the eye is plus) thats it. it can only get worse from there.

plus lenses on the other hand make vision worse. ie your eye isnt compensated. and to see it msut get more minus ie less myopic.

the point is that it is not quite correct to call minus lenses a crutch because they are pretty much permanent, ie your eye is very unlikely to improve while you wear them.

Close, Vic. You left out some important information: plus lenses are suitable as therapy those with MILD MYOPIA only, that is, if you can get around fine without glasses, and what you need is a little "overload"

distance blur to overcome. And even then, like any glasses, they can also cause headaches and eyestrain, especially at first.

I'll post the details on plus lens therapy later.

Or you can go ahead Vic, and post YOUR experience.

having worn + lenses for about 2-3 hours a day for the last week after work reading. I am getting almost continuous clear flashes during the day. :) I am extremely pleased with the results so far. I played with them in the past, but wearing them for a 2-3 hour at a stretch, only for reading seems to make a HUGE difference. highly recomended!!!

I dont believe there is such a thing as mild myopia. all myopia is noxious.

Dear Vic and Alex,

Your suggestions regarding wearing plus glasses when reading seem effective. I myself have been doing something similar for more than ten years. Since I am moderately myopic (-6.0 D) I use weaker glasses for reading (-3.0 D) which has the same effect as wearing plus glasses on emmetropic eyes. Initially, when my myopia was less, I used no glasses when reading.

I am astonished how many myopic people do just the opposite. They go around without glasses but when they sit down to read or work on a computer they immediately put on the glasses.

I will continue with the practice of changing glasses (or using plus glasses) for lack of a better solution. But what are we trying to achieve this way? We are relieving the ciliary muscle of the job of contracting the lens. I have dreamed of science-fiction glasses which change power depending on the distance you are looking at, so the ciliary muscle does nothing. In effect, this is an externalized lens. But how would you explain that some people have no problem with their eyes and yet do intensive close-up work? Genetics only? Maybe we should emphasize adequate training of the ciliary muscle as the key to long-term refractive stability.

I am near-sighted at around -2.5 both eyes.
When I wear plus glasses of +3.0, my eyes will attempt to adjust.
When I take off the plus glasses I have near perfect vision in daylight.

Even though the plus glasses work for me they do not seem to be changing the eye. In other words, if I am careful and use the plus glasses, my far vision is good, but if I use my eyes for near seeing (without plus glasses) such as reading my eyes go back to the -2.5.

It seems that my eye muscles are learning to see in a range and that can bring them to 20/20 but my eyes are still at -2.5. Any comments on this?

Subject: Blindfolds for better vision

I think a blindfold can be an excellent way to relax the eyes, especially when sleeping. I saw in a catalog yesterday an advertisement for a "sleep mask". They said light coming into your eyes when you sleep can inhibit melatonin production. I must admit I don't know what melatonin does, although it appears to be an important hormone.

All I know is that if I wake up with sun in my eyes, they're much more likely to be under strain when I open them. I once woke up in the middle of the night and found myself to have excellent vision and relaxed eyes. Then I went back to sleep. When I woke up, the sun was shining and my eyes were aching. I took this as strong evidence that light shining on sleeping eyes causes them to strain.

My favorite way of excluding light during the daytime, however, is the one-eyed patch. This actually lets me do something and forget that I'm doing therapy. This lets my unconscious take complete control. It also makes reading easier since the two eyes don't have to coordinate. Less brain strain. It also saves you eye-energy. But if you try this, I think it's good to switch patches every now and then so one eye won't get lazy! Robert-Michael Kaplan says in his book "Seeing Without Glasses" that 4 hours is the optimal amount of time to wear a patch.

Subject: Theory behind plus lenses

Here's a briefing for the newcomers:

Plus Lenses are convex lenses. They are available at most drugstores without a prescription.

They require your eye to focus less close up than without them. Thus they are used by people who see better in the distance (presbyopic, farsighted) to read. However, people with myopia can benefit from the use of plus lenses because they require the eyes to focus farther. They can be used as a part of a cure of myopia due to unresponsive muscles. Even people with elongated eyes may have part of their blur being due to unresponsive muscles.

Basically, putting a plus lens on makes you more myopic while you're wearing it. In order to see clearly, your eye has to focus further away than it would normally. But you won't be able to see PERFECTLY clearly, since your myopic eye doesn't have the range. However, the eye will improve, at least temporarily.

Essentially, the same thing happens to a person who normally wears glasses and then takes them off. After a while, you start to see more clearly without the glasses.

If you have ever had a less than full prescription, and then lost it for a week or so, and then put the glasses back on, you may have noticed that things were even sharper than they were when you were wearing them last. This is because your eye was allowed to stretch out, and now your old prescription is once again sufficient.

Plus lenses for myopia is just an extension of that idea. There are two varieties:

1) increase the daily amount of blur to stimulate your eye to focus farther. This means wearing the glasses whenever you would be otherwise just sitting there doing nothing. Not recommended for crossing busy intersections or operating motor vehicles!

2) use them with close objects (ie texts) so that they are seen just at the farthest still-clear point. Gradually increase the distance at which you can see absolutely clearly through the plus lenses. The same can be done without the lenses by backing away from a wall, but plus lenses reduce the distance necessary to get the same effect, so you can hold the object in your hand.

Before doing plus lens therapy, first you must be able to be comfortable living without your myopic glasses. Any improvement you make by the use of plus lenses will be counteracted by using myopic glasses.

About 1 year ago. I think it was -1.75 & -2.25

> 2. Do you ever actually wear -2.5D glasses? If so when? Do you wear another
> (previous) "minus" pair? What lenses are they?

I don't wear my latest glasses as they feel too strong and if I wear them
for more than 5 seconds my eyes quickly get worse.

I have a previous pair of -.75 & -1.25 which I wear at night when driving.

> 3. What kind of eye activities had you been engaged the month prior to
> this prescription? Studying hard? Outdoor activities? Had you been
> wearing glasses?

I am a computer programmer and I can't get away from looking at a
monitor. I wish I could spend my time outdoors and look at things at a
distance, but my job prevents this.

> 4. Who did you see, an ophthalmologist or an optometrist?

Just the standard eye-doctor when you go get inexpensive glasses.

> 5. Did they put drops in your eyes before they gave you the eye-chart test?

No, but he made me read a card with tiny letters and then darkened the
room and had me look at an eye chart about 20 feet away.

> How well can you see in each eye separately:

> 1. Through +3.00 lenses -- what is the far point (farthest point when
> things are absolutely sharp and clear)
> 2. With no lenses -- what is far point

I cannot measure this because my eyes are always changing slightly,
either getting better or worse, plus I will always attempt to blink them
and control them when seeing at a distance.

The far point may be 5 feet or 50 feet. I will also get clear flashes
that can last up to a minute. At night clear flashes are much harder to
achieve and they don't last as long.

I personally feel that in order for me to make continued progress and see
20/20 or 20/10 all the time I will have to work on relaxing certain
muscles in my eyes. - Tom Suliga

Simply bring a book to the drugstore and find a pair that you're
comfortable reading in. Most likely this will be the lowest power, +1.00
or +1.25.

Still, you may find that the high-power (+3.50 - +4.00) lenses have a more beneficial effect when used for distance viewing. After a minute, as you accustom yourself to the extra-high blur with the glasses on, you may find that your glasses-less vision improves astronomically when you take them off, if only for a second or two.

Remember, for this or any other myopia therapy to work, and to have lasting results, you have to wear your "minus" lenses as little as possible.

Status: RO
X-Status:

Hi,

I've been working to improve my vision, both on my own and with a behavioral optometrist. I've been working on some peripheral vision skills (among other things). I'm no expert, but I gather it helps with your overall vision efficiency (makes sense, I guess). So I thought I'd share a few things I've been doing.

My vision therapist gives me a different series of exercises every two weeks. The last series included an exercise with jacks. Yes, jacks. The kind you played with as a kid. I place one jack right in the center of the playing area, bounce the ball off to the left, catching with my left hand, and scatter the jacks to the right and pick them up with my right hand. While playing, you keep your vision trained on the one jack in the center. This forces you to use your peripheral vision on both sides simultaneously.

Another thing I like to do is juggle. (Juggling with three balls is simple to learn and fun!) While juggling, I try to move my gaze from the balls to something across the room, then back again. Again, it seems to require extensive use of peripheral vision.

Finally, I like to play the piano every day. When I first started vision training, I noticed that after playing for five or ten minutes, I would have a marked improvement in vision. This is distinct from other clear flashes in that it is not quite as sharp, but it lasts for much longer, sometimes for ten or twenty minutes at a time (while I keep playing). At first, I thought this was the result of relaxation (since I enjoy playing, and don't really *work* at it like some people). However, since learning of the importance of peripheral vision, I've wondered if that doesn't have a lot to do with it, too - since the way I play gets me using lots of it (I cheat and look at the keys all the time).

The nice thing about all of these things is they are more in the nature of play than work. I think everyone could probably survey their past and current hobbies and come up with some way to work a little each day on peripheral vision.

vics own "patented" myopia improver.

reverse newspaper reading.

get a typical newspaper, find a page with longest continuous

column. place it far enough away from you on a table such that:
the bottom of the column near you is readable but the top of the column
isnt. sit comfortably. pay attention to your posture. dont lean.
just to measure your progress see how far up the column you can see and
make a mental note.

now with one eye closed and with your open eye start from the bottom and
read up the column, till you cant make out whole words anymore.
then switch to letters. ie move up the page following any letters
you can make out. the simple rule is not to go up a line until you
can see a letter clearly. when you get stuck on a line and cant
make out any letter on the line above. just have a rest on the line.
maybe scan from side to side and often a letter from the line above
will come out. then you can progress up.

when you have gone up the column as far as you can, compare this point
to the first mental note you made.

then repeat with the other eye. then try it with both eyes open.

the obvious thing you may note is that the only way to progress into the blur
zone is by relaxing. so you just meander up the column with minimal
expectation and you may be pleasantly surprised.

now the best thing about vics own patented myopia improver is you
can do this at work without people looking at you strangely. they
just think you are reading the paper.

> I'm getting progressively myopic. I dont know my diopters rating, but it
> cant be that high. I want to get rid of these glasses.
>
> What is the best exercise to start with?

1. Never read books with your glasses on! And read as far away as is
comfortable. The more time you spend looking close up and the more close
up you look, the worse your myopia will get. This is the reason why
optometrists rarely give you "full correction" -- the adverse effects of
the lenses would be too apparent. What "minus" glasses (those prescribed
for nearsightedness) do is to bring everything up closer to you, optically
speaking. The distance of "infinity" equals the reciprocal of your
prescription in meters. For example if you're wearing -2.00 lenses, this
means that the moon is placed a half-meter away from you!

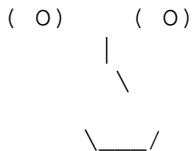

2. When you do read, always look up and away often. Have a familiar
object that you can look at and make sure that you can always see it as
clearly as you could when you started reading.

3. Exercise. Hold one thumb relatively close to your face and one at
about arm's length or a little nearer. Practice looking at one thumb and
then the other thumb. Try it with one eye at a time, using a patch. Then

do both eyes. Move your thumbs all around, in and out, back and forth, round and round, in every possible direction. Always have one thumb a little nearer and the other thumb a little farther, and as you're moving your thumbs, be focusing alternately at each thumb. This will exercise your tracking as well as your focusing. Remember to bring your thumbs off to the side, looking at them from every angle, not just straight out in front of you. You will probably find that you will need more practice at the peripheral angles.

- >
- > What acuity problems does the method portend to affect? How are the effects
- > identified?

William Bates said that his discoveries would help all people with eye troubles. The basic idea is to "look where you're seeing". The point at which you are looking should be the clearest, sharpest, brightest (or blackest, most vivid as the case may be) point.

Take a capital H, for example. Look at the upper left corner. The other three corners should be seen "worse" than the one at the upper left. If not, you're looking wrong. To correct, simply imagine that the part you're looking at is more distinct, or, what may be easier, imagine that the other parts are LESS distinct. Then shift to another point, watching

the image go in the opposite direction from your eyes. This illusion of motion is also important.

The ability to see one point best is called "central fixation"

Watching the image go in a motion contrary to how you're directing your eyes is called "swinging".

It usually helps, after a bit of swinging a letter up and down, left and right, to imagine swinging the letter, perfectly black, against a perfectly white background. Close your eyes and do the swinging in your mind, that is. Then open your eyes and look at the real letter again. It should be clearer.

>
> Relating to my specific problems, the discussions generally seem to center on

> direction - I can't see the close stuff, nor can I change my focus as rapidly
> as I used to (e. g. from the front sight to the target). Does the literature
> express any prognosis for the Bates Method in these circumstances?

Yes, as a matter of fact. Simply practice shifting in three dimensions! Get an eye chart or poster or calendar with big letters and shift from corresponding parts of an up-close letter to a far away letter, always seeing the part you're looking at best, and everything else worse.

You see, according to Bates, errors of refraction -- at any distance -- result primarily from the strain that comes from struggling to see too much all at once. Shifting and swinging help you to see just a little bit at a time and reduce strain, freeing your eye to focus properly.

I thought I'd share these blinking exercises that my optometrist once gave to me. They are very soothing and might make a nice addition to the other techniques mentioned in this group. They will also re-train your eyes to blink properly, avoiding the strain of staring.

TO LEARN TO BLINK COMPLETELY:
1- Close your eyes -- concentrate on feeling your lower and upper eyelids meet.
2- Keeping your eyelids closed, move your eyes left and right.
3- Continue for 2 to 5 seconds, then open.

Repeat for 1 minute every day for 3 weeks.

TO LEARN TO BLINK EVERY 3 SECONDS:

- 1- Count 1001, 1002, 1003, then blink.
- 2- Feel your lower and upper eyelids meet, then open.

Repeat for 1 minute every day for 3 weeks.

TO LEARN WHAT A RELAXED BLINK FEELS LIKE:

- 1- Place your fingertips at the outer corner of your eyes, so you can feel your eyelid muscles. Keep your head level.
- 2- Close your eyes completely in a slow, fluid movement. You should not feel your eyelids tensing.
- 3- Count to 3, then open your eyes wide.

Do this 15 times a day, pausing between repetitions.

As with any relaxation technique, the feelings/movements will become natural if performed consistently over a period of time.

The Flents brand patch that I use works well on both eyes.

> Which eye should I cover when reading books?

Well, if both eyes see poorly, you should alternate. I even think if one eye sees 20/20, you should *still* alternate, because vision can improve by eliminating light stimulation and letting your eye rest. When patching, each eye benefits in a different way: one by exercise, and the other by rest.

>
> How undercorrected should my work glasses be?
>

For reading, use a pair of glasses such that if you pull back just a bit, the text goes blurry. For people with moderate myopia this means no glasses at all. For people with low myopia, this means putting on PLUS glasses -- the kind they sell at the drugstore without a prescription. The idea is to give your eyes as distant a distance practice as possible. Remember, the less minus (or the more plus) in your prescription, the more "distantly" your eye must focus.

The following is an important point to remember:

If you hold out something a two feet away and it's blurry without glasses,

as far as the focusing mechanism in your eye is concerned, that's more "distant" than something twenty feet away that's perfectly clear through minus lenses.

Status: RO
X-Status:

I've been using this exercise for the past day or so; it's an application of Bates's "shifting" technique. I've been getting "clear flashes" as a result. Try it...

1. Go OUTSIDE.
2. Find a TREE, far away from you.
3. Now then. Position yourself squarely facing the tree.
4. Rock your head to the right. You can do the twisting either at the neck or at the torso. Try both.
5. As you do #4, observe the tree "swinging" to the left as you create a "virtual earthquake". You will only have to rock a few degrees in order for this to happen. The center of your gaze should now be at the right side of the tree.
6. Now rock back to the left, watching the tree swing to the right.
7. Do this again and again...
8. Tip for presbyopes: try it with your finger, too!

Let us know if this helps!

Howdy!
Sometime ago I was doing some Kata (in Karate: a set of pre-arranged movements, kinda like a simulated fight) and I realized that my form was not good (not that I have good form :-)) - well, my Sensei suggested that I breathe the next time I do kata (I was concentrating too hard on kata and holding my breath) - needless to say, my movements where much better. Now, I am sure that I am not the only one who forgets to breathe while concentrating hardly on doing something. I wonder if that affects our vision.....actually, chances are it does. Now, if I may, I have a breathing excersise I would like to share.

1. Sit down/lay down.

2. Close your eyes (if you want)
3. Take a deep breath, filling the lower part of your lungs first (belly will rise) and then filling up the upper part of the lungs. Imagine the air as some colored 'smog' filling in your lungs..
4. Count to 4 (as in one-onethousand - two-onethousand....)
5. Breathe out - repeat from 3.

Good luck! (and may you breathe for a long time :-)

Marco.

Never hit anything harder than your hand..... (from rec.martial-arts)

Thanks for sharing the thoughts on breathing.

I'm not sure 'smog' is the right word here. Frame of mind is very important. Perhaps a word with less polluting connotations can conjure up more appealing imagery for the energy we take in through our lungs.

Try 'fog' or 'energy' or 'light' or something: make it positive and nourishing.

Subject: shift & swing

Status: RO

X-Status:

Here is a description of the "shifting" technique of the Bates method. It works for all errors of refraction.

Cover one eye. With the other eye, regard a letter which is at a distance where it is legible, but a little indistinct. Look at the top of the letter and notice that the top is seen better than the bottom. Now shift your gaze to the bottom of the letter. Now the top is less distinct.

Repeat shifting your gaze from the bottom to the top of the letter, and notice that the letter "swings" in a direction opposite to the direction you are moving your gaze. When you look at the top of the letter, the letter appears to move down, and vice versa. Keep up the shifting and swinging and you will see the letter come into better focus. Shift to different corners of the letter, always seeing that part at which you are looking best. Do not squint or strain; remember to breathe and blink normally. If the letter does not move as it should, or if the letter becomes more blurry instead of less, this means you are under strain. Take a break, closing your eyes, breathing relaxedly. It helps to go over the letter in your mind, doing the shifting and swinging in your imagination. Then open your eye and try again. Some people find it easier to shift and swing on an object other than a letter, for example a window on a faraway building, or a doorknob...

You can also do this exercise with both eyes; I find it easier to practice with one eye at a time.

Subject: Extraocular Exercise
Status: RO
X-Status:

If you've been following the discussion in the sci.med.vision newsgroup (and perhaps if not), you'll know that most eye doctors think the extraocular muscles have nothing to do with how well you focus.

Even the behavioral optometrists will tell you it's useless to roll your eyes in an attempt to improve clarity.

And even Bates's exercises don't even seem to stretch or strengthen the extraocular muscles.

But I've been trying a very simple exercise based on the idea that poor refraction results from weak, untuned muscles -- and it seems to work, for me at least. If it gives you pain, stop!

Now then, here's the idea:

Keeping your head steady (but your neck relaxed) look up and to the left, down and to the right, up and to the right, down and to the left, look at your forehead, look at your chin, look way right, look way left, (and don't forget) look straight forward. Try going from one side to the opposite, tracing a square, or a diamond, or going out and straight forward for each extremity.

Now try it while following the motion of your eyes with your whole head.

Subject: vol.accomodation
Date: Fri, 30 Jun 1995 18:07:23 +1000 (EST)

Status: RO
X-Status:

Voluntary accommodation.

How to take control of the involuntary act of accommodation (focusing).

The first step is to develop some sensitivity to your sight, and the feeling in your eyes. Your brain controls the ciliary muscle, responsible for focusing, and like most involuntary actions can be brought under voluntary control, by finding it and exerting some "tightening" on it as you would any other muscle.

Remove any contacts and glasses. Begin with one eye closed, and with your open eye stand in front of a mirror, and look at the pupil of your eye, close enough so that you see it in focus (not so easy for very high myopes). Now shift focus between your reflection in the mirror and a more distant object. Note what happens to your reflection when you shift away. Now shift back. Again note what happens to the distant object. Repeat as many times as needed till you can perceive what effect the change in focus has on the image you are seeing in your mind. What you should be seeing is whatever you are NOT focusing on should more blurry than what you are. Once you are comfortable that you can detect the change in blur on the object you are not looking at, you now have to learn to notice the feeling in the eye as it shifts focus. Again with only one eye, shift from your reflection to a distant object in the mirror and try to detect the "tensing" that is happening in your eye as you change focus. That is the "feeling" you want to take control of, and you begin by trying to exaggerate that feeling of tensing as you focus close, or letting go as you focus further away. The feeling can be very subtle and may require a bit of concentration to locate. Once you have "found" where in your brain the connection is, you have tensed your ciliary. You can verify this simple by looking at your pupil straight on and "tensing" your focus, you should see your pupil go out of focus, and back in as you "let go", without moving the eye. Repeat this process of learning with the other eye.

You know should now be able to look at any object and voluntarily change your focus closer or further from that object without moving your eye away from that object.

more soon.

Vic

From: Alex Eulenberg <aeulenbe@indiana.edu>
Subject: Central fixation exercise
Status: RO
X-Status:

This exercise is designed to center your view, best done outdoors.

Look at a point on a distant object with one eye. Now imagine a line extending from that point to your eye. Depending upon the position of the object, the imaginary line will probably either seem to slope up to you or down to you. But of course it shouldn't! If you think about it, you

will realize that if there really is a straight line between that point and your eye, you should only "see" a point (because you're looking at that point head-on). As you do this, trying to see this line head-on, the image will shift a bit until the point on the object from which the line is extending is hitting you smack on the fovea centralis -- the central and most sensitive part of the retina.

Try it with both eyes, perhaps imagining a "V" instead of a line.

I've found this quite effective at heightening clarity, and when done with two eyes, depth perception. Please let me know if it works for you, or if you have any comments on how to make the exercise better.

When I first ditched my glasses, my prescription was -1.50. I think it took a couple of months before I felt "comfortable" without my glasses.

Health and nutrition make a big difference. Make sure you're getting the entire alphabet of vitamins and minerals, preferably in the form of raw vegetables, sprouts, and nutritional yeast (if you're not allergic). The B-complex vitamins (abundant in yeast) are good for keeping the muscles out of strain (but don't forget A and C -- also important!).

Be sure you spend a good amount of time each day outdoors when the sun is shining! Strange to say, I have found this to make night vision better.

I've found aerobic exercise (swimming in my case) to be essential to achieving full body relaxation.

- > I also

Once I put a meter stick down the back of my shirt. Worked like a charm! I could swear it even helped my vision!

>don't have the best seating posture and look at the keyboard when I

>type (typing lessons?)

>

>The question:

> So what do I do?

ok. I get this too. here is what I do. sit near a window and spend time looking out. put up a little eye chart a meter or so away so you can monitor the state of your eyes. make sure you get decent light in your office, either (preferably external) or daylight globes. (fluro is noxious). I have a proper chair to sit on. ditch any rubbish chairs. any time you find your self slouching, get up and have a pace around, then start again, sit properly. sitting properly is a habit that needs to be developed like any other habit. limit the continuous time you spend staring at the screen. make sure your screen has a high refresh rate, so it doesnt flicker at you. try viewing your screen in your peripheral vision (ie by not looking at it directly and see if you can notice the flicker {they all flicker}, this seems to help share the load) frequently.

try rubbing your hands to warm then up before palming.

acupressure and massage at lunch is great for relieving stress

for the afternoon. eyebright tea, either drunk or as a compress

does wonders for easing ocular tension.

I dont touch type, but would recommend learning.

If you are like me, you will find that progress initially happens

quickly but slows, then I have a habit

of "pushing" my eyes to see clearer. DONT TO IT.

always be gentle with them, just allow them find

their own level, and develop patience.

I like to be able to see peoples eyes when I talk to them,

when I first stoped wearing glasses, I couldnt see people

eyes if they were more then a few feet away, now I can see their

eyes at six to ten feet with no problems.

From: Alex Eulenberg <aeulenbe@indiana.edu>
Subject: Passenger seat Exercises
Status: RO
X-Status:

Elena <MBerezetsk@aol.com> shares the following exercise of her own discovery, which you can do while sitting in a car or bus or train... (DO NOT DO THIS WHILE DRIVING!!) Yelena's prescription is -7.5 -- considered "high" myopia, and yet she has achieved significant results...

* * *

Here's one of my recent "discoveries." As a passenger in the car, I breathe, relax, and start looking through the side window. I let the scenery slide past my eyes. I don't try to see anything in particular; on the contrary, I do something similar to swinging, just letting my eyes brush the fast-moving objects -- not even seeing them as objects, seeing only the movement of space. After a while, objects start "popping out" of this movement, here and there, but I don't chase them, don't try to prolong the instantaneous impression of seeing something clearly.

I alternate this with looking through the front window as far ahead as I can, again without straining or trying to see; I widen my field of perception and give nothing in sight any priority over anything else. Occasionally I outline the trees far ahead -- just the contour of the top. I look at the white divider lines, as far ahead as possible, but don't chase them when they move closer -- just keep on looking far, far away. The thought that I let recur while observing my perception is, "whatever comes, comes." I don't try to see the signs, the license plates, etc., but eventually they start "jumping" at me, spontaneously coming into focus. Again, I don't chase them, don't stare to "make sure" I saw them. Whatever comes, comes. It wouldn't be as amazing as I think it is if it wasn't for the fact that with my -7,5, I usually don't see any signs at all with my naked eyes. Imagine my delight when "Welcome to New Jersey" jumps at me from half a mile away, or when I suddenly read all the license plates in sight.

I also notice a lot of things that I never knew were there -- for instance, all the birds that happen to fly by over the highway.

Subject: Finger hopping for better vision
Status: RO
X-Status:

Here is a focusing exercise that I have found useful.

FINGER-SHIFTING

=====

With your glasses off, hold up the middle and index finger of your left hand and cover your right eye with your right hand. Lean your middle finger forward and tilt your hand toward you so that as you look at your two fingers with your left eye, they appear to be the same height. Now look back and forth, alternating looking at your left and right fingernails. Watch the one you're looking at go into focus, and the one you're not looking at go out of focus. IMPORTANT: Don't just look back and forth, but observe the texture of your nail, the minute reflections of light and shadow! This requires more attention and more accurate focusing than merely looking back and forth. Also: to avoid stiffening your neck, swing your head from left to right a fraction of a degree as you shift from finger to finger, in the same direction as the shift.

For the improving distant vision: Move your hand out until the index finger appears clear, but the middle finger remains blurry. Bring your hand inward until the middle finger is just barely blurry, and repeat

shifting back and forth between your fingernails until the details of the middle fingernail become clear when you look at it, too. Move your hand out again. If you start "losing" the details your middle finger, pull your hand back and repeat. After a few minutes, switch hands and eyes.

For improving close vision: same as above, but bring your hand closer; work on the index finger instead of the middle finger.

Variations:

Depending on the lighting, it may be easier to look at your knuckle-wrinkles instead of your fingernails. You also may want to use thimbles, or pair of detailed colorful "finger-hats" to look at, made of paper, of your own design.

If you are only mildly nearsighted, it helps to wear reading glasses while you do this (available for cheap at the drugstore). It brings your blur point closer, so you don't have to hold your hand out so far, and more finger details will be visible.

Instead of covering one eye with your hand, use a patch (also available for cheap at the drugstore). This frees up your other hand so you can do "thumb shifting" or shifting between any two hand-held objects, such as playing cards.

Please post any questions or comments you have on this exercise and its effectiveness.

--Alex

From: Betty Martini <betty@pd.org>
Subject: Re: Effects of bilberry
Status: RO
X-Status:

I've seen so much about bilberry on this network I decided to try it today. I've been on Internet since June and since then my vision has gotten much worse to where I have to use glasses to read. I happen to mention this to a friend and journalist in Chicago, and also mentioned that I had read articles about computers and vision loss. She said: "Didn't you know you're suppose to put sea salt on your computer?" I know that Haines makes a good brand you get at Kroger but I'm not sure what you do with it. Barb said she makes these sea salt containers up and gives them to people so she is going to send me one. You must wrap it in some material. I think she said something also about occasionally put it in the sun to energize it.

Also, on this network the other day somebody raised the question about vision and honey. I knew about that but had to look up in my notes where that material came from. For those interested this is the story:

Some years ago there was an article in the paper that vets use eucalyptus honey in the eyes of dogs to eliminate cataracts, and if I remember right it only took a couple of weeks. Somebody who read the article who had cataracts decided to try it. He too was cured of cataracts and wrote an article. Then everybody wanted to know where you got the eucalyptus

honey because it was hard to find. Another article appeared in the paper that said from: Moonshine Trading Company, P. O. Box 896, Winters, California 95694. It says on the jar (Gourmet Honey Collection). I bought it but never tried it and don't have cataracts. I thought my husband might want to try it because he has astigmatism, and if improves vision I thought it couldn't hurt to try.

The writer last week said that it burns somewhat. I don't know because I didn't try it. But they said you warm some water and put about a teaspoonful in it. In any event, this is where the story came from for whoever asked and I did have the original article.

Also, remember all of you never never never use anything with NutraSweet. It is a chemical poison and the methanol in it (wood alcohol that blinded and killed thousands during prohibition) converts in the retina to formaldehyde. A lady the other day said: "We must be getting older quicker so many of my friends are going blind!" My reply was: "No, they are not getting older quicker they are just using products with aspartame in it." We have a warning flyer we ask people to print out on our auto-responder on aspartame and help warn others. So anyone wanting the instructions please email me. I also have a post on methanol by Mark Gold that does a lot of research, my post on blindness and even Mark's research paper that contains some of the case histories taken off the net. We ask people to take the "no aspartame test" and then send us their case history. However, Mark's research paper is over 200 pages printed out. So anyone wanting information on aspartame specify if you want it or not.

On the auto-responder we also have a bulletin on how dangerous it is for diabetics to use NutraSweet. The ADA is funded by Monsanto so they recommend it but you can imagine would wood alcohol would do to a diabetic. We also now have an information sheet on NutraSweet and pregnancy and birth defects written by Dr. Roberts, the world expert on aspartame. We soon intend to put one together on aspartame and the eyes, and probably quote ophthalmologists and victims who lost their vision from this toxin.

Hope some of this information is helpful.

Regards Betty OPERATION MISSION POSSIBLE (the people working around the world to warn people about the chemical poison aspartame in an attempt to remove it from the marketplace --- and the planet. It is now in 90 countries of the world!)

Status: RO
X-Status:

I've never heard of Honey used that way.
Perhaps it works like a hyperosmotic.
It has been reported that Glycerin, can be used as a hyperosmotic to reduce corneal edema from "FUCH's" disease. It also hurts or stings.
The most common hyperosmotic is a 5% salt ointment, I prescribe it for recurrent corneal erosion. It is over the counter. "Murol28"

Warning:
Because Honey can contain botulinum toxin in low concentrations, it is advisable not to give to infants. I would give a similar warning to anyone planning to use Honey as an eye medication. If you want to use a hyperosmotic, try the 5% salt ointment by Bausch & Lomb, it is known to be safe and effective for many coneal porblems which cause edema.

At this time, it is not known to affect myopia, hyperopia, or astigmatism, in non diseased eyes.

If it clears your vision, it is because you have an undiagnosed problem. The most common epithelial basement membrane disease, will cause fluctuations of vision, frequent halo's around lights, and a sharp pain upon awakening.

Status: RO
X-Status:

The following is from "Drugless Medicine" by Suzanna Way Dodds, AM, MD, published in 1915, pp. 84-85:

* * * *

A good direction, either for preserving the sight or restoring it when weakened, is to avoid those things which would be injurious to it. Prevention is bvetter than cure. To strengthen the sight, and also to preserve it, an excellent plan is to live and work as much as possible in the open air and sunshine. It is a mistaken idea that habitually protecting the eyes from the average amount of light, will help to keep them strong. The tendencey is the other way; too little of it will weaken them. It is only in special cases and under certain conditions, that light should be excluded from the eyes. Light is the natural food for these organs, at least in day time, and it should be supplied in normal quantity. Many women injure the sight by wearing veils closely drawn over

the face, and particularly dotted veils; these are highly injurious. In every dwelling the living rooms should be well lighted, with windows judiciously arranged; and the inmates should avoid too much confinement indoors.

The eyes may be greatly strengthened by the free use of cold water; every morning in washing the face, dash an abundance of it over them. Cold water stimulates the capillary circulation in and around the eyes, and helps to strengthen them. The writer knows individuals who have practiced this habit all their lives, and who are able to read without glasses long past middle life.

Subject: Blindfolds for better vision

I think a blindfold can be an excellent way to relax the eyes, especially when sleeping. I saw in a catalog yesterday an advertisement for a "sleep mask". They said light coming into your eyes when you sleep can inhibit melatonin production. I must admit I don't know what melatonin does, although it appears to be an important hormone.

All I know is that if I wake up with sun in my eyes, they're much more likely to be under strain when I open them. I once woke up in the middle of the night and found myself to have excellent vision and relaxed eyes. Then I went back to sleep. When I woke up, the sun was shining and my eyes were aching. I took this as strong evidence that light shining on sleeping eyes causes them to strain.

My favorite way of excluding light during the daytime, however, is the one-eyed patch. This actually lets me do something and forget that I'm doing therapy. This lets my unconscious take complete control. It also makes reading easier since the two eyes don't have to coordinate. Less brain strain. It also saves you eye-energy. But if you try this, I think it's good to switch patches every now and then so one eye won't get lazy! Robert-Michael Kaplan says in his book "Seeing Without Glasses" that 4 hours is the optimal amount of time to wear a patch.

Subject: Theory behind plus lenses

Here's a briefing for the newcomers:

Plus Lenses are convex lenses. They are available at most drugstores without a prescription.

They require your eye to focus less close up than without them. Thus they are used by people who see better in the distance (presbyopic, farsighted) to read. However, people with myopia can benefit from the use of plus lenses because they require the eyes to focus farther. They can be used as a part of a cure of myopia due to unresponsive muscles. Even people with elongated eyes may have part of their blur being due to unresponsive muscles.

Basically, putting a plus lens on makes you more myopic while you're wearing it. In order to see clearly, your eye has to focus further away than it would normally. But you won't be able to see PERFECTLY clearly, since your myopic eye doesn't have the range. However, the eye will improve, at least temporarily.

Essentially, the same thing happens to a person who normally wears glasses and then takes them off. After a while, you start to see more clearly without the glasses.

If you have ever had a less than full perscription, and then lost it for a week or so, and then put the glasses back on, you may have noticed that things were even sharper than they were when you were wearing them last. This is because your eye was allowed to stretch out, and now your old prescription is once again sufficient.

Plus lenses for myopia is just an extension of that idea. There are two varieties:

1) increase the daily amount of blur to stimulate your eye to focus farther. This means wearing the glasses whenever you would be otherwise just sitting there doing nothing. Not recommended for crossing busy intersections or operating motor vehicles!

2) use them with close objects (ie texts) so that they are seen just at the farthest still-clear point. Gradually increase the distance at which you can see absolutely clearly through the plus lenses. The same can be done without the lenses by backing away from a wall, but plus lenses reduce the distance necessary to get the same effect, so you can hold the object in your hand.

Before doing plus lens therapy, first you must be able to be comfortable living without your myopic glasses. Any improvement you make by the use of plus lenses will be counteracted by using myopic glasses.

> (previous) "minus" pair? What lenses are they?

I don't wear my latest glasses as they feel too strong and if I wear them for more than 5 seconds my eyes quickly get worse.

I have a previous pair of -.75 & -1.25 which I wear at night when driving.

> 3. What kind of eye activities had you been engaged the month prior to
> this prescription? Studying hard? Outdoor activities? Had you been

I am a computer programmer and I can't get away from looking at a monitor. I wish I could spend my time outdoors and look at things at a distance, but my job prevents this.

> 4. Who did you see, an ophthalmologist or an optometrist?

Just the standard eye-doctor when you go get inexpensive glasses.

> 5. Did they put drops in your eyes before they gave you the eye-chart test?

No, but he made me read a card with tiny letters and then darkened the room and had me look at an eye chart about 20 feet away.

> How well can you see in each eye separately:

- > 1. Through +3.00 lenses -- what is the far point (farthest point when
> things are absolutely sharp and clear)
- > 2. With no lenses -- what is far point

I cannot measure this because my eyes are always changing slightly, either getting better or worse, plus I will always attempt to blink them and control them when seeing at a distance.

The far point may be 5 feet or 50 feet. I will also get clear flashes that can last up to a minute. At night clear flashes are much harder to achieve and they don't last as long.

I personally feel that in order for me to make continued progress and see 20/20 or 20/10 all the time I will have to work on relaxing certain muscles in my eyes. - Tom Suliga

Subject: Eye Exercise: Zooming
Status: RO
X-Status:

Here's a simple exercise often recommended by those who otherwise don't believe in eye exercises.

Look at an object some distance away, then look at an object a further distance away. Look at the first object, second object, first, second, zoom, zoom, zoom!

It helps to do this rhythmically.

It also helps not to bite off more than you can chew, that is, don't switch between your thumb two inches from your face and a building a half mile away. It's better to have your near object relatively far away, say at least arm's length, to avoid strain. The action should be snappy and effortless. Importantly, watch the near object "go double" when you look at the far object and vice versa. This will indicate that you're using both eyes.

For starters, use the thumb on your outstretched hand as a near object, and a tree as your far object. When you look at the tree, the tree should be right in the middle between your two thumb images. Conversely, when you look at your thumb, you should see two tree images surrounding your thumb.

Try this with your head at different angles, up, down, right left, and always keep the zoomed-on object centered between the two images of the un-zoomed object. Experiment with different distances of the near and far object with different sizes of objects, under different lighting conditions; let us know what works!

It is primarily an exercise for the extraocular muscles, and is designed to improve depth perception. However, a side effect seems to be that it smooths out the cornea by regularizing the tension, because astigmatic "ghost images" go away for a time when I do this.

If you try this, please report your experience to I_SEE.

--Alex

PS

For evidence that the extraocular muscles affect corneal curvature, and that a misshapen cornea results in single-eye double images (monocular diplopia), check out the sources in the bibliography, "The Incredible

Changing Cornea" at

From: Alex Eulenberg <aeulenbe@indiana.edu>
Subject: Eye exercise: Flashing
Status: RO
X-Status:

"Flashing" develops your visual memory and sensitivity. It also reduces eye strain because, with a well-developed visual memory, you will use less energy re-scanning a scene to make sense of it. Just the same way musicians with a good audio memory only have to listen to a melody once and they've memorized it. And of course, when eye strain is reduced, acuity is always improved, too.

Now, the exercise:

Close your eyes and you will see an "after-image" of what you were looking at. Watch the after-image fade away. After the after-image fades away completely (a few seconds) open your eyes for a flash and take a "snapshot" of the surroundings. Keep them open only for the length of a blink. Think of a flash as a reverse blink. When you close your eyes, do it gently; don't slam your lids shut. Keep flashing and see how much you can see with each flash. Look at the scene as if your eyes are still open. When you open your eyes, see how much you remembered.

Like all exercises, this is especially good to do outside on a bright sunny day. I wouldn't advise it while crossing a busy intersection, though.

From: Alex Eulenberg <aeulenbe@indiana.edu>
Subject: Re: Eye muscle exercises
Status: RO
X-Status:

Most experts on the matter of eye exercises all seem to agree that the purpose of doing eye exercises, especially in the case of myopia, has absolutely nothing to do with building muscle mass or "strength", but in coordinating the muscles. The training really effects the motor centers in the brain, not the muscles per se.

It has often been said that myopia results from a "cramped ciliary muscle", the ciliary muscle being the muscle inside the eye that focuses the eyes for the nearpoint when it contracts, by changing the curvature of the lens inside the eye.

So far from "strengthening" this muscle, eye exercises for myopia are usually said to work because they "relax" the ciliary muscle.

But things are not that simple.

Here is an exercise that has given me a noticeable improvement in distance acuity, but it seems to be working on the extraocular muscles, not by "relaxing" the ciliary muscle. I believe it works partly by "ironing out astigmatism" and partly by coordinating the focusing with the eye-crossing.

Take a yard (meter) stick, edge up, and extend it away from your nose. Look at the near end of the stick. You should see a "V" composed of two stick-images. Your left eye sees the leftward-veering stick-image and vice versa. Now slide your focus up the stick as slowly as possible, keeping the two stick images in view. The "V" should turn into an "X", the crossing point being the place where your eyes focus. It makes it easier if you tilt the stick slightly upwards. You can also help yourself at the beginning by sliding your finger up the stick and focusing on that. Always keep the two stick-images in view. When you make it to the top of the stick, you will see a "^" (inverted V). As you do this, make sure that the point you are looking at (the crossing point) is clear, and that both eyes are working (you should always see two sticks). Go up and down and up and down. Vary the distance of the stick and the angle at which you look at it. Rock your head back and forth as you slide up and down the stick.

Blink your eyes and look around. What do you see?

Unbelievable! Quick, go right to your eye doctor and get a new prescription! I bet it's already gone down. You probably don't need glasses that strong to drive.

> suggestions? I also seem to have a lot of trouble seeing the swing of a
> letter when I look from right to left. The movement of the letter seems
> to want to go the same way as the motion of my eye.

First of all, make sure that the chart is not too far or too near. If it is at an extreme distance for your eyes, nothing will be anything near clear, and this will induce strain.

Secondly, if you're not seeing what you should, the best thing is NOT to try, try again. Instead, if you can't see it, close your eyes and IMAGINE it. Then open your eyes and look again. Imagine the swing, imagine that one part of the letter is blacker than the rest. You can do this on a mental image as well as on the actually-seen image. Look at the top of the "A"

and imagine that it is pitch black, while bottom is more or less dark gray. Shift from part to part and do the same thing. Imagine that the letter swings up as you shift from the top to the bottom of the letter. Same for right and left, and oblique motions. There is a fine distinction between "imagining" and "trying to see", but it is fundamental. Imagining implies no effort, while trying implies effort. As Yoda said, "Do not say 'try', say 'do'" Bates said: if you can't do it in reality, do it in your mind first as practice.

Secondly, it is important to secure mental relaxation FIRST. It will rarely come about as a RESULT of practicing the swing. You should only practice when you feel relaxed. Often, physical or sensual relaxation techniques can help induce the mental. For example, listening to your favorite music. Also, it's good to have a familiar object, an "optimum" as Bates calls it. It might be a favorite photograph or piece of jewelry. Looking at it brings you relaxation, as well as practice at relaxedly looking. When you don't have the object, you can close your eyes and imagine it.

Thirdly, it always helps to forget about your eyes. Yes, this is very hard to do when involved in an eye exercise. One way out of this is to swing your head, NOT your eyes. It really doesn't matter what moves the eyes. It is an artificial distinction to say that the extrinsic muscles of the eyeball are "vision muscles" and the neck or torso muscles aren't. All are intimately connected with the process of seeing. Often I have found that when I relax my neck or stretch my side, my vision improves, and I feel relaxation in my eyes. You are still moving your eyes when you swing at your neck, but since you aren't "concentrating" on your eyes (and perhaps for other reasons too), it can be more visually relaxing than voluntarily shifting your eyes in their sockets.

>"Axis 001, 177" Please don't remind me how bad my vision currently is, ouch.

Thanks for the opportunity to comment on your prescription and make suggestions for a reduced one. Firstly, your numbers aren't that bad. I have seen worse. Begin to accept that your vision is developing. Let go of the belief that your vision is bad. Very important! The big challenge is the difference in prescription between the eyes. I would suspect that your "naked vision" is better through the -2.00, -150", which I assume is your right eye? The choice you have is to reduce the spherical prescription equally in front of each eye or more before the right eye in order to stimulate your perception through the left. In my experience, I would suspect you could cut back the spherical part of the prescription by between 1.00 and 1.5 diopters. This means you would leave the cylinder alone for the first reduction. I will be posting an article at another time on why this is important. The new prescription would read R-0.75 -1.50 axis 001

L -2.50-1.25 axis 177. You should be able to drive in good light with these numbers, although the doctor would need to confirm this. Please bear in mind by just wearing weaker lenses does not guarantee that your vision will improve. In my experience you will need to actively use vision training during the day. The FAQ will give you additional steps. I hope this helps. All the best. and thanks Alex for the chance to give feedback.

Marco: Here's a cold shot response to your question. The whole basis of a weaker lens prescription is built on the concept of adding plus. The

critical point is that the amount of plus needs to be determined, because the reduction in minus affects the binocularity. Lastly, you will still need to practise specific exercises if you desire to lessen your dependncy upon glasses and improve your eyesight. Many of my patients go out and buy the maginifying reading glasses to wear over their contacts.

Plus is cold! Robert-Michael

Subject: Determining a "fitness glasses" prescription
Status: RO
X-Status:

On Fri, 22 Sep 1995, Abigail Fermo Abinoja wrote:

> Could anyone recommend a good behavioral optometrist in the St. Louis area?
> I went to one referred by the Optometric Extension Program Foundation but
> he informed me that vision can't be improved short of surgery.

That reminds me: Always call your doctor before you make the appointment -- find out about their attitudes toward vision improvement. Some, even supposedly behavioral optometrists, are have a more "compensation-only" philosophy than others. Some, for example, will refuse to prescribe therapy of any kind to adults.

> I wanted a
> pair of fitness glasses but my prescription went from Spherical: -200, -400
> Cylindrical: -150, -125 Axis: 001, 177, to a prescription of Spherical:
> -2.50, -4.25 Cylindrical -1.00, -0.75 Axis 010, 165. Is this much of an
> improvement, at least towards a pair of fitness glasses? I don't know how
> to interpret those numbers.

Basically, the amount of negative sphere is the amount of nearsightedness correction (positive sphere is for farsightedness), and cylinder is the amount of astigmatism correction. Astigmatism can be thought of as an extra bit of myopia (or a little bit less) at a certain angle. Since a cylindrical curve is twice as powerful as a spherical curve, the strength, or "spherical equivalent" of your lens is computed by adding the sphere and half the cylinder. Axis has nothing to do with strength; it's merely the angle at which the cylindrical part of the lens is placed.

So one eye went...

$$\text{from } -2.00 + -1.50/2 = -2.75 \text{ to } -2.50 + -1.00/2 = -3.00$$

while your other eye went...

$$\text{from } -4.00 + -1.25/2 = -4.63 \text{ to } -4.25 + -0.75/2 = -4.63$$

So your prescription really hasn't changed that much in terms of spherical equivalent. One eye's prescription has been increased by a quarter diopter, while the other is the same. The only improvement I can see is that the amount of astigmatic correction has decreased. This means your glasses are less "warped".

You want to have no cylinders if at all possible. Cylinders create clarity at the expense of distorting objects to different degrees. Perhaps you recall during an eye exam being told to choose between two lenses, one yielding a fuzzy but properly proportioned image the other a clear but distorted one. The eye can learn to see more clearly without cylinders, as the unwarped visual environment stimulates the internal and extrinsic muscles to pull the eye back into shape.

I mentioned earlier that balance between the eyes is considered important by many vision therapists, so ultimately, you want not only the weakest comfortable prescription, but also the prescription with the least difference between the eyes. Note that the stronger a myopic lens, is, the more it reduces the size of what you see. You want both your eyes to be looking at the same sized objects.

So here are some general guidelines for helping you choose a pair of fitness glasses:

- * 20/40 vision (good enough for driving, but leaving room for improvement)
- * The least amount of cylinder -- none if at all possible.
- * As similar as possible strengths for both eyes.

With these guidelines in mind, you should be able to work out a good fitness pair of glasses with your optometrist.

Before you go, make sure you can try out the glasses in a real world environment with test frames before you leave the office -- don't be satisfied with putting your head in a box and looking at letters. And don't let them dilate your pupils, which will temporarily worsen your vision. You want to know how good these glasses are for your eyes in their natural state.

Above all, call before you go to avoid disappointment. Remember, all optometrists have invested a considerable amount of time in learning how to prescribe "the correct amount of cylinder", and many will be offended when you tell them you think no cylinder is good cylinder. However, if you are confident about the issues, you can usually get kind of prescription you want. But make sure your doctor is willing to work with you on this. Otherwise you will waste your money and your time.

>other eye, repeat the process, and voila - both eyes are cured. Do
>you think that the severe imbalance in the eye's would be more
>detrimental?

yes. I dont think its a good idea. inbalances in the muscles of the eyes are called various phorias. I am no expert but methinks you would strongly be encouraging disproportionate amount of musclar development. and upset any synergy in the various systems.

one of the basic premisses of Bates is that lenses upset the delicate balances between accommodation, convergence and pupil dilation. these three are governed from a single nerve bundle from the brain. the official literature even hints that contacts cause less rapid progression then frames.

I think there is little cause for concern in having to purchase many pairs of glasses/contacts. these only occur in 1-2Ds increments so in my case -2.25 I need only 1 transitory pair. a -6D may need only 2 or 3. this would be spread out over some time, unless you are lucky enough to have very fast progress. remember though progress is measured in months. you also have to remember that when downgrading power in glasses you are just changing the lens and not paying for yet another mega expensive frame. contacts: you may get away with just using disposables on certain days of the week. if you already use these then there is no added cost.

what I did was basically go cold turkey. I stopped wearing contacts entirely. which I used to wear from waking to sleep. now I keep handy a pair of glasses in case I need to drive. the first week was a disaster. but after that it was ok. progress was brisk, and I became complacent expecting the momentum of improvement to just carry one without any further effort on my part. nah. so back to basics. I found its important to make VT a routine task like brushing teeth. if you are what is considered low myope < -6D (amazing inst it) it may be possible to minimise the amount of time behind lenses. if you are mild < -3D (how -3D can be mild is beyond me) then going cold turkey is quite feasible. it does seem clear to me that the less time you can spend behind corrective lenses the faster you will progress.

one thing I would say is that prior to begining any course on VT, I would strongly recomend getting a full ocular check up, preferably with a behavioural optom. you will get a much friendlier response. to check the state and health of your eyes. and to keep an official measure of improvement.

Vic: I have seen the subjective findings in some cases, and others the
retinoscopy findings change this fast when an active Vision Therapy
is undertaken. The difficulty is th variability of the findings and therefore
the repeatability. It will depend which day and at what time, the person go-
es
to the Doctor's office.

Bill: I came in on this a little after the initial posts.
Are you referring to a best visual acuity

refraction or a cycloplegic? Will you be comparing retinoscopy with the manifest subjective?

Thanks, Robert-Michael Kaplan.

Have you read the new book: The Power Behind Your Eyes?

Bill's answer:

Haven't read it, but from what I hear Chopra's pretty far out there...

I was referring to the manifest refraction as measured by neutral practitioners (who *must* be unaware of the bet, of course).

this is interesting. cause sometimes I can get a clear flash by
blinking, but the longer I try to hang on to it, the more some
stress/pressure builds up somewhere in the eye which results in tears.
I wonder if this is related.

> > your eyes are drying out, they react by secreting tears.

again I dont agree. cause I can hold my eyes open for quite a while
without any tears. but this is diferent I can feel various forms of
tension/pain which force the tears. I doubt its as simple as the eye
pushing against the tear ducts or eye fluid spilling into them.

I also get differnt types of clear flashes. the best of which results
in total relief of any pressure or tension and perfectly clear vision.

another type which I call artificial flashes come about by blinking
and isnt sustained for more then a short time. the later also results
in tears. the former doesnt. both go away with blinking. although I
have just been able to make it through a couple of blinks with
the real thing. :) I suspect the artificial flash comes about from
the blinking and various muscles sort of falling/tightneing/stretching

into place.

as for tears/liquid on the eye changing the refractivity I get these as well but these are the least stable, and you can in fact notice uneven clarity which gets moved around by blinking, I don't count these as proper flashes. and anyway you can always feel the moisture in your eyes. so you can tell what is going on.

I, too, get two very distinct kinds of clear flashes (I've gotten into the habit of referring to them as "real" ones and "cheating" ones). The real ones are accompanied by an incredible sensation of relaxation around my eyes, and are not affected one way or the other (either started or ended) by blinking. I don't have the ability to bring these about by will, but I can create the conditions favorable to them by various relaxations techniques.

The cheating kind of flashes are caused by blinking in a somewhat peculiar way, or simply by tensing and then relaxing all the muscles around my eyes. They almost never last more than two or three blinks. I can now bring these about any time I want to, and it's actually a useful skill every now and then, if I want to see something for a few seconds, but not run and get my glasses.

What I find interesting is that I tried vision therapy on my own about 10 years ago, and only experienced the "cheating" kind. In spite of my learning that skill at the time, though, I lost it when I quit doing VT (in favor of orthoK). I remember halfheartedly trying to do it a couple of times in the interim, without any success.

So, although I now consider this type of clear flash to be not the real thing, I've concluded that 1) it definitely is a skill that came from vision therapy, not one that I had all along, and 2) it seems to be a precursor of the real thing. Let me make it clear here that I'm no vision expert, but from my perspective, the "cheating" flashes are just a stop along the path to better vision.

One thing I've been amazed at in my latest venture into vision therapy is how many completely different ways of seeing things the same pair of eyes

can come up with (blurry, double image, multiple image, clear with halo, or perfectly clear). It seems very odd that no one has tried to scientifically research and explain this.

I have been trying to experience the 'clear flashes' thing using various different methods without success.

The other day, I was lying down in bed, facing the ceiling. There was a ceiling fan right above the bed, so I was looking at the fan blades turning as I was lying down. As my mind wondered, I thought I got a clear flash for a split second from looking at the moving blades.

It all happened so fast that I am not sure if the flash was for real, or just my imagination. The problem is, I can not repeat the experience anymore no matter how long and hard I tried.

Can anyone confirm if one could get clear flashes by looking at turing fan blades, or was my experience a sub-conscious, wishful, foolish thinking?

Thanks

Andy

Ok!

I have another one. I started fooling around with +ve lenses (1.25) and on my second day, I felt a 'thump' (or a 'click') in my eyes (both) kinda like a muscle contraction (or relaxation) and viala, it was all clear for some secs (then I blinked :- (). Can somebody explain that?

Thx.

A common experience is to have everything all clear until you blink. Skeptics of vision improvement say this is because you "blinked off" a film of tears that was resting on your cornea, a kind of natural contact lens.

However, if tears could improve vision that well, certainly clear flashes would be more commonplace.

If, however, you suppose that good vision is maintained by the extraocular muscles -- the ones that point your eyes in different directions -- we may have a clue.

I notice that whenever I blink or otherwise move my eyelids, I get a kind of "earthquake" in my visual field. It seems to be a kind of reflex of the extraocular muscles to move the eyes when you blink, which all too often can disrupt a clear flash.

Fortunately, it is also common experience that over time, clear flashes become more resistant to blinking.

* * *

But how do you get your clear flash in the first place? I've found that clear flashes are more likely to occur just after a small snack. I've had good results with orange juice, carrots, and especially brewer's yeast. I hesitate to recommend any particular vitamin supplement, since I believe that each person has their own "something lacking". Find out what your missing link is!

Your body should be relaxed but alert. I have a hunch adequate blood sugar is essential. Physical exercise is a good way to achieve this state. Clear flashes come more easily when I'm lying down. Another excellent way to bring about a clear flash is to go to a musical concert. Bright light or at least being outdoors (even if it's cloudy) also seems to be very important. I can't remember ever having a clear flash in a dimly lit room.

With that in mind here's a recipe for a clear flash:

1. Have a workout, take a shower
2. Have a healthy snack
3. Put on your favorite music, or go to a concert
4. Lie down and look at something under bright light -- don't stare at it though, shift from detail to detail.

If it doesn't come, close or cover your eyes for a few minutes or seconds and look around some more. Shift your gaze to the beat of the music.

In my experience, clear flashes show up just about any where. blinking one's eyes often leads to them. Looking at the world through a window screen is also a good way to get them.

you can never be sure about spilt second clear flashes. I always consider a real clear flash to be multi second at minimum, now I can tell if one is comming on because it has a characteristic signature of feeling about it. at first you can never really make one happen, and my first was totaly out of voluntary control. the more you tense, tug or pull or at muscles in your eye the less likely you are to get one. you sort of have to allow it happen by leting go of everything. just by sittin gback and being a pure observer, allow your unconscious mind to adjust itself and your vision without conscious override. its that conscious override which proably got you myopic in the first place.

It appears that blinking can both bring on and destroy a flash of clear vision. What's going on? I think the best analogy is banging on an electric appliance. I agree with Zarin that the improvement is ultimately something "neural". But I disagree with him when he says that the reason for good or bad vision is in "image processing." I think what is happening is that some nervous energy block is released (or knocked out), perhaps in the brain itself, perhaps closer to the eyeball, allowing the correct focusing signals to finally get to the eye.

> or nothing" vision improvement seems just like a mental process to
> me.

Again, I disagree with your reasoning. If the improvement were in the
inherent physical properties of the eyeball, then yes, you would expect a
gradual improvement. But if it is the "focusing system" as you say, which
is controlled by a "mental process" then there is no paradox. What we
appear to be dealing with is a deeply-ingrained myopic (or astigmatic,
or hyperopic for that matter) reflex.

> One question that I have for all of you who have experienced clear flashes:
> Have you ever seen a blinking or moving object in your clear flash?

Yes! Examples: rustling leaves, birds, clock second hands... and the
entire scenery moving as I sway my head back and forth.

But, you're right... it does seem to be easier to get a clear flash while
looking at a stationary object. However, tracking a moving object is as
much a physical challenge a mental one.

What I'm getting at is that focusing is a matter of PHYSICAL COORDINATION.
What changes in vision improvement is the mind's ability to coordinate the
physical structure of the eye.

I've had experiences every once in a while when things suddenly seem very clear, and this usually stays for a minute or so even if I blink. But I've especially noticed clear vision after opening my eyes in my swimming pool. I don't know whether this is an effect of the water in the pool merely cleansing my eyes, or some sort of visual property the chlorine has, but when I come up from opening my eyes underwater, I notice things to be sharper, brighter, and more colorful.

That's just my experience.

Subject: Weird clarity
Status: RO
X-Status:

When my vision gets clear -- and it happens a lot nowadays -- I have to deal with two weird problems. The first one is just unbelievable -- I can only describe it as an allergic reaction to clarity. (I have no history of allergies whatsoever.) My eyes start watering (which entails grave consequences for my eye makeup -- you guys have no clue unless you're Michael Jackson), my nose starts itching, and I often sneeze. For now, I trashed makeup and went natural, but I need a more permanent solution. (Again -- I'm not allergic to makeup or anything else, it only happens as a result of a clear flash.)

The other problem is pain. With maximum clarity comes maximum pain -- and it's not your common everyday eyestrain, it's unbearably sharp (like when you're cutting an onion too close to your face). All I can think of is that in my native tongue, the saying that corresponds to "truth hurts" is, verbatim, "truth pinpricks the eyes."

Has anyone experienced these symptoms? My original myopia is high and my difference between "clear" and "original" is several diopters. Does anyone have an explanation? Suggestions?

Elena

true story. My eyes often start watering and I get a pain in the eye itself if I do an induced clear flash. my nbehavioral optometrist says this passes with time, and thinks its the EOMs misadjusting things nearby when they re-adjust to see properly.

I wish I had a solution to this. next time you get a clear flash try blinking as *lightly* as possible at any indication of tears or pain and see how long you can maintain the clarity without effort. to me it always seem the effort is what trashes them.

>I am convinced it is neural processing, ...

I am not convinced clear flashes are neural. firstly
I can get a pain in the actual eye, and blinking makes mine go away.
secodnly if it was nerual then the brain should be able to
switch it on any time.

>I really hope I'm wrong and this improvement is really in the focusing
>system, but I haven't seen any sign of it.

its not in the focusing, (ciliary) as I can accomodate at will and
this does nothing to the clarity (when released :)

>One question that I have for all of you who have experienced clear flashes:
>Have you ever seen a blinking or moving object in your clear flash?

yes. I watch cars down at the airport the size of ants racing about,
which I cant even see normaly!

I don't lose it with a blink any more. I find I can keep it as long as I don't look at things with significant difference in distanceI suspected the reason would be that the mind attempts to use a different filter algorithm as soon as the focal distance changes and in doing so it loses the old one which lead to the clear flash.

I have to say that I find this discussion a bit pointless because neither of us have real experimental data for our guesses. I will explain the background a bit more, because I think I owe it to you since I brought up the subject, but I don't have any real proof, so I will not respond again because that would lead to infinite loops of discussion. Sorry Vic, you asked me this on SMV too and I never responded, because I didn't know what to say.

As far as banging on an electric appliance goes, that's a really bad idea too and it would be much better to understand what exactly goes wrong and fix it rather than random banging!

>
This is not my original idea. In fact at first I resisted it a bit too because I was really excited about the new improvements and didn't want to believe that there was no real improvement.

After impressing a physicist friend with reading distant things without glasses (things that he as a myope with a lower magnitude persc. can't read) he wanted to try it too. I showed him the tricks I used and within a few minutes he noticed a change too. Then he borrowed my Bates book and I think spent a few hours reading it and tried more of the stuff I do.

His conclusion was that all I did was I trained my mind to correct the blurr in the same way that people train neural nets. He does a lot of neural net programming. Up to that point I had been convinced that what I did was closing the feed-back loop for the eye control system, so by reminding my brain what I expected to see it would "adjust" the control signal to the muscles to achieve it.....and I thought the clear flash was the rare times when I relax the muscles 100%.

Just a quick explanation: Neural nets are modelled after the brain. People train them using a training set (a set of things that you know how the net should respond to) and measure the error between the response of the net and the expected response. Then they change the net's parameters and do this training again and again using stadard optimization methods, till the error is minimized. In principle you could use a neural net to enhance a blurry picture that a satellite took as long as you could use a known feature in the picture and get the net to massage the data till the feature looks like what it should.

This sounds very much like the exercises with eye charts or anything you might do if you try to see things as what you know they should look like.

I have come to accept this neural training theory after noticing that it was the only explaniantionthat fitted all the evidence that I had. I am going to list them here so you can think about it and decide for yourself, but since I don't have real experimental data, even I am not 100% sure so I am not going to re-hash them and get to a long discussion and clutter everybody's mailbox.

- Everybody seems to get clear flashes regardless of their eye problem. Bates even got people without lens (cataract patients) to see some things.

If there is a real defect like short eye-ball or no lens (or no control over the lens for some reason) or miss-shaped cornea, I can't believe that any exercise "fixes" the *REAL* optical error, but neural image processing can be trained to work on a number of distortions.

(Don't get me wrong some problems with eye alignment seem to require some exercises, but that's not myopia.)

- Richard Mccollim's post with info. regarding the lens elasticity suggests that no matter what causes the lens to remain convex (this could be some sort of stress induced cramping of the muscles or just prolonged near work) after the lens is kept so convex for so long, it will lose some of its elastic property and might take years for it to return to normal.

So no matter how relax the muscles get, how relaxed you are, how much you have gotten rid of the "myopic personality" and near work, etc. etc. the lens will not return to normal right away. Think about it as an over-stretched elastic band, or a super-compressed mattress even when you remove the destructive force, they don't spontaneously return to normal for brief seconds and return to the deformed stage. Either they recover the original shape slowly or they don't.

- Robert-Micheal Kaplan mentioned something about people being able to see better, but the refraction tests not changing at all or only a little after all these years of study that he did.

- My clear flashes are very static. Remember I am a -4 myope. If you Alex or Vic get a clear flash because you're not so myopic, it's bound to be better than mine, because your natural system is not as "broken" as mine.

For me it is still very amazing that I get them, but I notice that I can see things that are far, but if I try to see something close it's ruined. At the same time I don't have a problem turning my head and seeing all sorts of far things and keeping the flash. Even moving cars as long as seeing them clearly while they are moving does not represent a significant change in blurr. Same thing goes for when I see close stuff, I can't just shift to seeing far stuff.

- If I have a clear flash outdoors in bright light I don't notice the haze, but if I do it inside, I notice the whole picture is a bit hazy and yet I see sharp edges around letters and things far away.

- Another bizzare thing is that even after wearing glasses for a while and even after being very tired and stressed out and having worked through the night, I can still get clear flashes. A few times I had to wear glasses for the whole day (for the past 4 months I've not been wearing them almost 90% of the time), and I expected to have really blurry vision after taking them off, but to my surprize I even got better results than before, as if the new memory of "what sharp should look like" helped me in seeing better.

- Since I became myopic slowly and the effect was gradual, I would expect any solution to the same problem should be gradual too.

- Sometimes when I am trying to see some far object, I notice the way my mind is actually changing it. Sometimes it scales up or down or stretch it sideways and I can see it's just playing with the image to get it right.

All of the above points plus a few other minor ones that I don't bother with have lead me to believe that the improvement is caused by the mind's ability to post-process the blurry image. It is still amazing and I think should be studied and perhaps this will allow people whose myopia is stress induced to wear weaker or no glasses before it's too late. Of course

it's also great for people with other vision problems.

But for me a "real" improvement would have to be something that returns the natural elasticity of the lens, because if you have work/stress induced myopia, not matter what caused it, the physical effect is in the lens and unless you fix that, you havent fixed the problem.

But I don't have proof for any of this. I just wanted to share it with you because I thought my friend had a great insight that for the first time explained all the things that seemed inconsistent to me.

>
The reason I don't believe this any more is that if the lens loses it's
original shape and flexibility, there is nothing the mind can do to fix that.

> > One question that I have for all of you who have experienced clear flashes:
> > Have you ever seen a blinking or moving object in your clear flash?

> entire scenery moving as I sway my head back and forth.

>
Yes, but sorry my question was phrased poorly. I get all of that too, but
if things are roughly as far away from you , then the mind does not
need to re-learn the processing "parameters" that it used. I even believe
that it can remember and recall a set of parameters for different distances
(Blurr factors), but it cannot smoothly give you a clear image while you
shift your eyes from close to far or far to close....something that I would
expect if the lens was working, because the process of changing shape is
a continuous process.

> But, you're right... it does seem to be easier to get a clear flash while

>
The mind cannot flatten the lens back to shape if it is "stuck". Time might,
but the mind can't. The best the mind can do is "let go" of the ciliary
muscleswhich is a good start.

> --Alex

>
Now that I explained myself, I'll keep quiet because I have no real proof.

BTW, Elena, my eyes watered for the first month and my whole face would be totally wet. But now it only does a bit, doesn't burn any more and it stops watering after one second or so.

Cheers,
Zarin

Please confirm:

The flash stays for some seconds. My eyes seem to be more light sensitive (by A LOT!!!) when it happens, causing discomfort and watering.

The other problem is that it seems to only happen to my right eye (it is less myopic). Also, the flash is accompanied by some sort of double vision, resulting in a slight blur in the top part of the vision field.

For example, I would be able to trace the bottom parts of the letters of the words I am seeing, but the top parts of the letters are blurry due to the double vision. Could it be caused by the fact that my left eye did not the flash?

I think this is the real thing. Could anyone confirm this?

Andy

thats it!! you got it.
there are various flavours of this. the extreme is when both eyes get
simultaneously and wow! you'll find that double vision has always been there
in some degree or other but know you are noticing it more.
cover each eye in turn with your hand next time it happens to
check whats going on with each eye. double vision is astigmatism
more or less. possibly some fusion as well.

Alex (and anyone else interested):

As you well know, the occasional posts to sci.med.vision on
flashes of clear vision are answered with condescending remarks by
the professionals. They are probably unaware that there are a few
reports in the literature on this phenomenon. On re-reading a paper
on "The resting state of accommodation" (Meredith Morgan, Am. J.
Optom. and Arch. Am. Acad. Optom, Monograph 214, July 1957), I
came across the following:

"Le Grand, using skiametry, found five subjects who showed
negative accommodation during "flashes of clear vision" while
wearing too much convex lens power...Morgan and Olmstead,
using skiametry to measure changes in the refractive state of the
eye, reported that sudden sensory stimuli, such as an electric shock
or a loud noise, may cause a sudden decrease in the refractive
power of the eye, usually not more than 0.25 D."

I noticed the same effect from a hard fall when hiking in the
mountains--a flash of clear vision. I wonder if anyone else has had
a similar experience. The comment about "wearing too much convex
lens power" suggests a way to provoke flashes. How about wearing strong
convex lenses while exposed to a loud explosion and receiving a strong electric
shock! :-) (Would that produce a .75 D. reduction in lens power?)

Hm... Something to keep in mind for those of us staring at black and white letters all day. Which reminds me, a certain optometrist William M. Updegrave wrote a book in 1936, called "The Seeing Eye", and each page was printed with a different colored ink on a different colored piece of paper. He requested that readers write him and tell him which pages had the best effect on them.

A few months ago, there was a discussion on the cause of clear flashes. One theory is that the flash was caused by image processing done in the brain to "compensate" for the blurs.

I think I found a way to test this theory. Take a picture of a familiar object. Make the camera out of focus, so the image will be blurred. Now look at that picture, and see if your brain can "process" the image so that the object in the picture looks clear to you. If clear flashes are the results of the brain's image processing, you should be able to do this. If not, then the theory is not valid.

I think this should work. Comments?

Hi Andy,

I put forward that theory and I also suggested that particular test (actually neither the theory nor this particular test were my original ideas, but came from my discussions with a physicist friend when I was trying to figure out what was going on).

I still haven't done it. I only have an automatic camera but it has an option for fixing the focus on a particular object, so I was going to put that in my far focal point, fix the focus and then remove the object and ask somebody to hold a letter (or a few letters) in front of the camera but further away than my focal point and take a picture. To be totally objective I need 2 other people and I should not be on the room, so that I can not see the letters in advance.

I think if I could manage to see the out of focus letter it would prove the theory, but I am not totally sure what it would say if I couldn't see the letter. It is not too easy to control this clear flash process and how would you stop your brain from focusing on the edges of the actual picture and your hands etc. rather than try to look at the contents of the picture? This process is a bit automatic. Another thing is that I am pretty near sighted, so should I do this test with my glasses on or off? What is the effect of the additional distortion in either case?

So I agree, if the test is successful, it proves the theory and although I don't believe the reverse holds, I think it is still a very good test.

But I must say that so far using binoculars or my own glasses (that are too weak for me) I haven't been able to do the same thing as I do with naked eye...ie I couldn't compensate for the insufficient focus. That could just be due to lack of practice since I am used to getting clear flashes without any lens in front of my eyes. Since the principle behind both ideas is the same, I always thought I should at least learn to do it with my glasses on (ie try to read signs with my glasses on that I usually can't see) before I go to the camera test.

.....but now that you brought it up I might get inspired and do the camera test and report back to the list!

I have used Andy's idea in slide presentations and have found that the audience can usually guess the image at about 20/40 or 50 level of blur. It is amazing how accurate they can be. I use one particular slide of a sunset with boats, and many can see the boats when they are quite blurry. I know the skeptics will say this is blur interpretation, but 3 lines of eyesight clearness is more than interpreting blur. Any thoughts?

Hi Zarin,

Actually what I was thinking was setting the camera focus to the

nearest/shortest position possible, and hold the object slightly beyond.

Say your focal point is 30cm, camera was set at 10cm, picture of object was taken at 15cm from camera. Now you get to look at the picture at 25 cm (your focal point minus blur distance of camera).

> I think if I could manage to see the out of focus letter it would prove

>
Definetely do this with glasses off. To preven the "edging", make sure there is nothing else in the picture (obviously), use ??? background color on the picture, and neatly paste the photo onto a large piece of paper with the same color as the background. This way you field of vision will be covered by the paper, and there will be nothing else to focus on (you can always paste the picture to a wall so you don't have to hold it).

hi,

quick intro: hi I am Vic, 32 I am a computer guru, :)
and comited to restoring my sight to something useable without
cutting. an old boss had the operation only to "regress" within a couple
of years back to glasses.

And to be without lenses. I had been spending
upward of \$500/year of cleaner/pills/saline new lenses.

I currently dont wear any corrective muck except when I drive.
current prescription was at 26/april/94

R -2.25 -1.00x175
L -2.25 -0.75x178

and yes I get clear flashes too.

with the advent of massive proliferation of the net, I see this
as an ideal opportunity to counter the "self-interest" of the
optical priesthood by disseminating usefull information to
those who need it.

Vic

Hi.....I am Marco.....I am myopic....

Ok ok ok....sorry, but I could not resist...:-)

Since Alex E. requested that we each introduce each other,
here is me.

I am an Undergrad in the Univ. of N.H. (5th year Senior). My major
is Psychology although I am now more dedicated to computer science.
I wear contacts and I do not like it. The idea of eye-surgery
does not appeal to me so I am always open to any option that
could give me a 20/20 without a laser beam cutting my cornea...:-)
Well fellas... that's all. Oh..before I forget....I am also
a wannabe Marital Artist (for those of you who understand my .sig)
This is me (can you tell I'm a newbie to this list)?

Cheers!

--

Hello everyone,

My name is Stan and I'm 21 and an undergrad at UCLA (in Los Angeles,
California). Actually, I'm currently taking time off from school to work
on a programming internship, but that's another whole story...

I've worn glasses since the third grade and have minor nearsightedness
along with pretty bad astigmatism. I'm not very knowledgeable about
things of this nature or improvement methods (yet) but look forward to
learning more and reading posts to this group.

Furthermore, I spend about 16 hours a day staring at a computer screen
(limiting my social life to ytalk-ing to my girlfriend 3000 miles away),
and I've noticed that my eyesight has gotten progressively worse and
worse in the past two years. Coincidence? Probably not. I'm not
planning to be a fighter pilot, but keeping my eyesight past the age of,
oh... 24 might be a nice thing too.

Oh, in addition, despite my looking quite normal and looking like I'm
in pretty good shape, the fact is that I eat junk food, never eat
anything vaguely healthy, and am probably lacking any vitamins which
might be of even partial help to the eyes. I plan to change this.
Tomorrow. Or the day after. Well, eventually.

Cheers to all. Glad to join the group.

-- Stan --

 Subject: Vision Therapy
 Status: RO
 X-Status:

I'd like to share my experience with vision therapy. I started taking a course with the Natual Vision Center in Austin, TX, around March of last year. The course is based on the Bates method.

When I started my contact lense perscription was -7.5 in both eyes. I didn't feel like I had really stuck with a lot of the vision games as much as I should after a few weeks . . . the newness of it wore off. But I was wearing an underprescribed pair of glasses so my vision would be 20/40.

The eye doctor I went to was familiar with the Bates method, but he told me not to expect a lot of improvement. I choose to totally disregard any discouraging words from him since my VT instructor knew of a fellow in California who had improved -11.00 diopter vision to normal!!

Anyway, I went back in November, and he said he was very impressed with my improvement. Suprised is more like it!! My contact lense perscription is now -6.0!!

I only wear my contacts for outdoor activities (rock-climbing, etc. when I absolutely have to have the acuity.) Otherwise I wear my 20/40 underprescribed glasses for driving and other activites. Additionally I got a pair of glasses that were prescribed just for reading. That way I don't have the additional strain of the 20/40 lenses for close up work when I don't need it.

The main thing that our instructor focused on is blinking, breathing, and sketching (not staring). Shifting, palming, sunlight, and several other things were also taught, but those first three are the "main course" for vision improvement.

I'm going for a follow up VT class in 3 days, and I'll be heading back to the optometrist in May for another check up. I'll keep everybody posted.

In my excitement to put up that last post I forgot to tell everyone about the progress I've made!

My contact lense perscription (yes, I'm still wearing them occassionally, but I'm cutting back more and more!) went from a -7.5 to a -6.0 in about 8 months.

Also, I no longer have any problems with light sensitivity.

Great stuff!

Alex, I wanted to give you an update on some vision improvement. I started vision therapy in March of 1994 and my contact lense perscription was -7.5 in each eye. I have backed down my perscription 3 times since then, the latest about 1 week ago. My current contact lense perscription is R -5.0 and L -5.25. I've found an optometrist who is very supportive of vision therapy - she actually took the course with my local instructor! I'll keep everyone posted as my eyesight continues to improve.

John Richter

ALSO - If anyone wants to talk to a Natural Vision Therapy instructor , you can call Jeanie Fitzsimmons in Austin, Texas at 327-5683. Tell her I said hello!

Status: RO
X-Status:

hi,

just a quick note regarding the psychological aspects of myopia.

last monday I visited a behavioural optometrist and aside from the sheer benefit of an encouraging professional opinion I got prescribed "functional" lense a diopter weaker then I was wearing. my first reaction was to put the new lense into an old frame as the current -2.25s allow me to read the 10 foot line at 20 feet ie 40/20 vision. (way better then normal). but then I thought what the hell, sink or swim, and decided to "give up" my current pair, and am getting the lense in that frame replaced with -1.25s. my current vision is around -1.5 for 20/20. these I will pick up next monday.

well the week has passed without having the convenience of

knowing I can pick up my glasses whenever the need may arise.
ie. I have to rely solely on my own powers of accuity.
and what a surprise, I have had so many "clear flashes" this week
I am beging to wonder wether my -1.25s will be too strong for me!

in fact I have had so many I have been actually "retraining"
my accomodation, rather than just being in "awe" when it occurs.
accomodation in myopes is usually very weak due to disuse. so now when
I get a "clear flash" I accomodate from infinity (airport on
the horizon from my work vantage point) to my computer screen
in from of me and back again. and I am finding this little exercise
seems to extend the clarity beyond the length of time i usually
have it for. and I have also found that I can blink and still
maintain my clarity. which is a first for me.

my thought for the week:

seeing is like sex. its all in the mind. :)

Vic

yes and no. I am not really in it for the credit. my hope
is that the information will be of benefit to people.
and should be made as freely avaiilable as possible.

>As a matter of fact, last fall I discovered the magic of the yardstick and
>I think I know what you're talking about. I considered my experience doing
>fusion at various angles plus zooming from the end of the stick to various
>objects to be proof positive that the extraocular muscles have a
>tremendous effect on maintaining proper acuity and eliminating
>astigmatism.

yes its very similar. except with a bit of string you can make it as long
as you want, and the coloured beads give you something easy to fuse.
at first I found that past about 4-5 feet, my vision seems
to choose a single side to concentrate on. this came as a major league shock
cause I alway thought I had great binocularity, I can do all the stereograms
with remarkable ease. and with fusion I can consciously make a side disapear
and then the other. but that was all at close distance.

my bit of string is about 10 feet long with a bead every 8 inches or so.
the first night I basically couldnt get much stable diplopia (hell
might as well start using these words since I know what they mean :)

past a few feet. I am going to keep working at, I am finindg it quite relaxing, almost like metidating, I just let my eyes move up and down the string while I think about something else. I am also finding my accomodation has extended up the string a bit. I can actully watch the focus change when I suddenly move from a bead to another. I find my accommodation is pretty slow. also I find my astigmatism is very spasmodic, it sort of jumps in and sometimes I can make it jump out. which to me really strongly suggests some sort of muscular action. not really corneal flaws. today i sort of vaguely worked out how to make things almost 100% clear, with only a faint second image. but soon as ai stopthinking about it, it reverts...its almost like I am finding my eoms one by one. I can already do conscious accommodation (have to get around to puting instruction for that in the FAQ)

the other intersting thing is my unaided vision for short periods of time will actually go beyond 20/20. which i suspect is its normal state. my old script gave me around 40/20. my new script is undercorrected. (yes there is a god) and often I can get 20/20 or slightly better with it. I have an apointment with my behavioral optom. but he is booked out till may. (maybe there isnt a god) and it turns out he also does syntonics... and recomends a course of that... once upon a time, I wouldnt have even considered doing something like shining coloured lights into my eyes, but given the attitude of the optoms on s.m.v. I now think if it worked for some people there might be something in it. even if we dont have a theory to back it up. he tested my colour field of view, and while I have a normal field of view, the colour perceptions are very skewed, as far as I know they are supposed to be fairly round... more on this in may.

on a different note, I got another email from a behavioral optom on s.m.v. how come these people never stick up for themselves??? he assumed I was a behavioural optometrist. :) that investment in duke elders optom book was pretty worthwhile, I might look for the other duke-elders ophthal book.

someone actually replied to Jeff Crabtree. he will have to reply back. no one seems to reply to me :(they all have seemed to agree to ignore me. methinks that someone is telling them how to use kill files. might do a fake post as me but a slightly skewed address to get past that little bit of nonsense.

have you read suddenly successfull.(Dawkins, Edelman, Forkiotis) about behavioral optom. full of cases, but very little on insider details. I want a text on the nitty gritty of behavioral optom... there is a course at NSW uni, on behavioral optom, I will try and get the course notes.

Vic (patiently waiting for permanent unaided 40/20 sight...)

Howdy,

I just subscribed to this newsgroup a few days ago. I'm a grad student in computer and information science at OSU. I use computers too much and my eyes are pretty bad, to be more precise, one of my eyes is much, much worse than the other one. My dad has the same problem BTW. My left eye is lightly near-sighted, while the right one is much worse. And guess what, the right one is getting even worse at a rate faster than the left eye! Anyway, I hope my eyes get better. Later

Subject: Vision Freedom
Status: RO
X-Status:

Hello again,

Thanks for responding to my post so soon. I already had the appointment with Dr. Westgate about two weeks ago. He said that he hadn't heard of VF or Mr. Severson. While I was there I just paraphrased the 60 page booklet I'd received in the mail to Dr. Westgate. He was familiar with the technique of accommodation to improve vision but said there weren't many studies on its success and that in my case (-4.25 Left, -4.00 Right) there wouldn't be much improvement.

I didn't get the impression that he was trying to mislead me or anything. From his experience and reading he just hadn't seen data pointing to vision improvement for anyone using accommodation or biofeedback procedures.

I have to share a bit of my history to you:

I've been under the care of Dr. Joel Halpern O.D. while going through orthokeratology for the past four years. Initially my acuity was in the 20/400 range for both eyes. After about seven months of the OrthoK I could see the 20/30 line on an eye chart with my right eye...20/50 with my left immediately after removing the lenses.

Unfortunately, the effect doesn't last very long (eight hours max) and now the best I can see when I take the Ortho lenses out is 20/70R 20/100L. I am a pilot and college student studying Airway Science. My goal is to fly for a major airline but I'd rather fly for the Air Force. I could pass a Class I physical needed for the airlines as I am now.

My hope was through, vision therapy, of increasing my acuity to the point of passing the Air Force vision test. From reading Mr. Severson's booklet this goal doesn't seem out of reach. If I could make drastic improvement with my acuity to say 20/60 in each eye with vision therapy or more specifically Vision Freedom I could get down to 20/20 using Orthokeratology.

Why am I sharing all this? Dr. Halpern has helped me a lot and I don't want to lose his support. I originally asked him about the VF booklet and he then set up an appointment for me with Dr. Westgate to see if he knew anything about it and if it would benefit me. They operate under the same practice, Halpern Eye Associates. As I stated earlier Dr. Westgate's news was not what I wanted to hear but I think he was being honest with me. With my next office visit with Dr. Halpern he told me about a seminar he'd just been

to concerning the excimer laser and it's use for PK and how a U.S. firm is refering patients to Canada for treatment.

Here's my dilemma. PK would disqualify me for an Air Force commision as would any other surgical technique to modify the refractive power of the cornea.

I'd like to go the Vision Therapy route but my doctor doesn't have any data concerning significant improvement for myopes or anyone else. While undergoing OrthoK I can't effectively use the techniques outlined by Brian Severson. Dr. Halpern told me that he would be more than happy to help me in any way he could but he'd need evidence of vision improvements in other patients, data, or something to those effects in order to justify the suspension of my OrthoK treatment at this point.

Could you send me, Dr. Wesgate, or Dr. Halpern any information on other doctors who use plus lense therapy or the book titles you listed in your last message. I'd really appreciate it.

--ps I the Prodigy Browser to get the FAQ at http://silver.ucs.indiana.edu/~ae ulenbe/ but it wouldn't accept the address. Is there another way to get it?

Thanks for your time

X-Status:

Hi all,

I'm Mikko Salminen, a second year student of computer science at Helsinki University of Technology. I got my first glasses when I was about 15 years old (5 years ago).

I don't really know why I became nearsighted. Perhaps it has something to do with my lifestyle in those days. I took school more seriously than ever before. I did (all) my homework and read quit a lot. Sometimes I didn't sleep well (that's what I do nowadays :-)) so I was tired and my eyes were too. But maybe it has nothing to do with that. My both sisters got glasses at age I got mine. Is that just a coincident?

When I got my first glasses I hated those but soon I started to use glasses every day and every minute. In five years my vision has become worse and worse. My first lenses were -1.25, nowadays -3 and -3.25 :(

In the meantime my sisters used glasses as little as possible (they said they looked more beautiful that way). They use glasses only when they really need to (like driving or watching tv). I guess it's needless to say that they both have better vision than I have.

I really need glasses in my everyday life. Only at home I cat put glasses away. Have you any suggestios what to do? I don't like idea staying home and just copying all the lecture notes.

IMHO, this is a toughy. I hated reading in grade school and high school because I didn't find out until college that I was far sighted. At that point I got a prescription for reading glasses and discovered the joy of reading. Had it not been for an intense need to read in order to thrive in the college environment, I would never have sought correction, and might still dislike reading.

Had a school nurse diagnosed the problem earlier for me, as for your daughter, I suspect I would have enjoyed grade school and high school much more (as I did college).

I suppose the members of this list would say to take that knowledge and seek natural vision improvement rather than optical correction. I did the latter and am now near sighted. I suspect that I would still have become nearsighted after the college and grad-school experience, but perhaps not as much, if I had been aware of natural vision improvement techniques at the time. On the other hand, I might not have done as well in college if I had not taken immediate steps to correct my problem. (I went from an A/B average my first semester to straight A's for the rest of my college career partly due to this effect).

Scott

wear your glasses where you need them. dont wear them where you dont.
use 20/40 correction glasses where you need some vision but not full vision.
if you are < -5d myopic you should be to read a book without glasses.

when my younger brother first got glasses he hated wearing them
and only wore them in class, never out of class. once he got
to uni and spent most of his time in lectures he had to wear
them "full-time" and he says during this time his

script got worse and worse really quickly. Similar story to Mikko's sisters.

there are two possible causes for myopia. environmental and genetic. Environmental causes should be reversable. Genetic may or may not be. some people have a genetic pre-disposition to visual problems. this does not necessarily mean these are not correctable.

some possible explanations for environmental myopia.

straining at the near point. basically reading for hours at a time to the exclusion of the distance vision. distance vision simply fades away. A young girl that had spent her life "under the stairs" because of a crazy mother. had no distance vision when she was finally rescued. anything that is not used atrophies.

straining at the far point. overachievers or frustration with blackboard material. trying "too hard", to make sense at the far point. resulting in strain or a withdrawal from the far point and introversion, back to the safe and understandable near point.

boredom with the far point. is another possibility.

imitation of a parent with glasses. is yet another.

here is a reference specifically for children. I have not read this book, but when I get a copy I will incorporate it into the FAQ.

"Your child's vision: A parent's guide to seeing, growing and developing."
by Richard S Kavner. O.D. 1985.

>From: mwillis@zephyr.ess.harris.com (M. Scott Wills)

You have to decide what trade-offs you need to make to reach your goals. If you are going to undertake a vision therapy during study, then this can be difficult, due to your restricted time constraints. and the general pressure to do well. but its not impossible.

>I just wanted to add that I had an extremely bad year of school when I was 7 because I desperately needed glasses, but my parents wanted to prevent my eyes from getting worse. The teacher made fun of me because they were trying alternative methods which didn't work.

you can see how this would help :(

>Things were so
>much better when I got the glasses. It is quite likely my eyes got so
>bad because I started doing hours and hours of reading a day when I was
>6. Nevertheless, (and I know no-one on the list is suggesting otherwise
>) it is very important to provide vision correction to children when they
>need it.

most people dont really notice a -0.25-0.5d change in vision very much.
-0.25d means things outside of 4 meters become a little blurry.
children often get by -0.5d without glasses simply because they
dont know better.

if problems are caught and corrected at this early stage then there
may never be a need for glasses.

I did not get glasses till I was over -1d at age 21 simply because I
did not want them. someone lied to me and told me if I wear
them for a little while my sight would improve and I wouldnt have to
wear them again. where in fact once I started to wear them my sight
got worse to the point I couldnt do without them until now.

once you have gone past about -1d then you need glasses for certain
activities. glasses only compensate and will not cure any problems.

simply not wearing glasses will not improve your sight, you have
to factor in what is causing your sight to degenerate. and attend
to those issues. things like posture (very important) and other
physical, emotional, mental, diet, lighting condition, etc.
as well as rebuilding your vision with exercises etc.

I spend about 8-12 hours in front of a computer screen every day,
and still I have managed to improve my sight by about 30% over the last
six months.

Vic

Here's my story. I'm a linguistics/cognitive science grad student. I was
introduced to the Bates method by a Russian girl who ended up to be my
wife, when I was 22. Actually, she was 20/20 and never needed to use it
(until now, when the ocular stress of grad school life has been taxing her
RIGHT eye). At the time I had a -1.50 both eyes prescription and always
wore my glasses. Actually, before I had heard of Bates, I was already
trying to improve my vision. I reasoned that if singers could improve
their vocal range, why couldn't I improve my focal range? I just stopped
wearing my glasses, and found I could improve just by walking around on
bright sunny days. Later I started to read as much as I could on vision
improvement. Now I'm 25 -- still myopic, but the last time I checked my
myopia was under a diopter in each eye. Every so often I go on a
patching-plus-lenses-and-lots-of-nutritional-yeast binge and my acuity
shoots way up for a few days. On several occasions I have been able to
read the 20 line at 20 feet indoors. My progress is kind of bumpy, but I
feel I'm on my way. I find a lot depends on nutrition and exercise no

matter how much visual training I do.

I have started a mailing list, I_SEE (International Society for the Enhancement of Eyesight -- to join, send "subscribe i_see" to <majordomo@indiana.edu>) and have a WWW site with vision improvement materials -- <http://silver.ucs.indiana.edu/~aeulenbe/> -- but you may know about this already...

I had been participating on sci.med.vision since mid-November until just recently. I couldn't take the heat. If the thread "Alex's Platform" is still on your newsserver, I suggest you read that one. Also "Alex Surrenders" should give you a good idea of what happened to me.

I am especially interested in non-Helmholtzian theories of accommodation, and in the extraocular muscles as a source of refractive error -- the recti causing astigmatism and hyperopia, and the obliques causing myopia. I have read Myopia Myth by Donald Rehm, and Bates in the original. I believe if there is to be a revolution in eye care, it must come from without. I believe Bates lost because he advocated a treatment that could be administered without a license -- not even the most progressive optometrists would go for that (e.g. the OEP will have nothing to do with Bates).

Ok.
Since We have lots of new members - I guess I'll re-introduce myself. My name is Marco - I go to the Univ. of New Hamp. (5th year senior). I am 22 - I am majoring in Psychology & Comp. Sci (kinda) with a minor in Busines. I am a beginner Karateka (Shotokan), I meditate and I like Kilians Red (or Catamount).
I have 1.5 and 1.75 I believe. My left eye has astigmatism. I took the Silva Mind Control Method - in which they have had some reported cases of dramatic improvement. I wear GP contact lenses which are great when you practise martial arts (try Sparing when somthing gets in your contact lens in the middle of a fight...ayayay!). I am, as you see, very sarcastic.
I hope to, one day, aquire the 20/20 vision (Alex - I have am reading Bates, I know this is merely an average, don't flame me! ;-), that day will be a day of great embarrasment though, since I paid top dollars for contact lenses that I am hoping to stop using...I have started a program of eye vision improvement (some exercises et al.)
Well - enough blabber. Send me e-mail or read my homepage (WWW) if you care to know more about me!

Cheers!
Marco.

I was 42. It was a 4th nerve paresis combined with some exotropia. An inferior oblique and a lateral rectus were weakened (recessed), so this means that the lateral rectus was moved back, away from the cornea. The inf obl is already in back, nowhere near the cornea. I believe that the surgery had no effect on my astigmatism, other than psychological. I was more aware of how things looked after the operation (because my diplopia was cured in most directions, but I had new diplopia in others). Bottom line is my astigmatism in the operated eye went up from -.50 by maybe .25 or .50 diopter. (Same for the eye that wasn't touched!) I am confused that you say "surgery increases astigmatism"; it would seem in some cases like mine to have a chance of decreasing it. Maybe I don't understand.

I've taken a while to respond to Alex' command to reply to his message. I hope you're not all sick of hearing similar stories.

I'm in my 40s. I teach computing, love to read - all the classic myope things. My sight is around -10 in my better eye. I hardly use the other eye. I wear a contact lens in the better eye. My sight has deteriorated continuously since the age of about 14. However since learning a little about natural vision I have managed to avoid a change of prescription for several years, but my sight hasn't actually improved.

My main worry is retinal detachment. I have had 3 of these (in the better eye). Two needed surgery and one was laser treated. I am scared that one day they won't be able to fix it. Has anyone any ideas? I've read in the FAQ about bilberry. Would it help? Is it available in tablets etc? What do I look for?

Has anyone other ideas - or similar experiences so we can commiserate?

Looking forward to hearing from some of you.

Hello, Everyone! I just joined the list and would like to introduce myself. My name is Barb Ruchkall, I'm a Research Analyst in the Office of Institutional Analysis, University of Manitoba, Winnipeg, Manitoba (Canada). I'm 47 years old, and up until about 40 years of age I had great eyesight.

Once I turned 40, I started noticing that my arms were becoming way too short. My watch became illegible, especially in low light and people would shove papers at me too close to my face. In other words, I developed what I'm told is presbyopia. I bought a pair of reading glasses.

I hate the blasted things! At first, I just didn't wear them much, but lately I find that I need them more and more. I'd been wondering if there was something I could do to strengthen the muscles that control accommodation ... seemed to me, these muscles should respond to exercise the same way other muscles in the body do. And it also seemed to me that the saying "If you don't use it, you'll lose it" would apply to those muscles as well. One day, I was surfin' the 'Net, and I came across the Natural Vision Web Site. And so, here I am!

There are some other potential problems that I have: An ophthalmologist discovered that my eyes have the appearance of glaucoma, although my pressure is normal. I have large optic cups, or some darned thing. Kinda like Dolly Parton but in a less noticeable place. My field tests have all been normal, but I've been labelled a "glaucoma suspect". I visit an ophthalmologist whose special interest is glaucoma, and he "keeps an eye on me". Another potential problem is that I have an inflammatory bowel disease and have to take prednisone from time to time. Prednisone can cause cataracts and glaucoma. Needless to say, I avoid prednisone if possible.

I have an eleven year old son who has a convergence problem...If he does the pencil exercise as described by BrAek in a previous post to this list, there is a point at which he begins to see double. His optometrist suggested that he do the pencil exercise, trying to focus on the pencil until the point that his vision becomes double. He also suggested that we place a postage stamp on the window, and have our son focus on the postage stamp, then look thru the window at something far away, then back to the postage stamp, etc. etc. These exercises seem to help, and I was quite impressed that the optometrist suggested exercises instead of glasses!!

I'm glad to be on this list and look forward to any of your suggestions.

Barb

What does this mean?? How do you notice things better when you can't see them all too clearly in the first place.

> the first goal is to start getting clear flashes. ie crystal
> clear sight which at first may only last a few seconds.

I think I had one of these. This morning when I woke up, after my eyes adjusted to the light, for a split second there, I could have sworn that I was wearing my contacts. Everything was clear. Is this possible after only doing the exercises for one day??

Also, everyone I tell about this thinks I've totally turned into a flake, because they think it's nonsense. Is there any truth to what they are saying???

>--Thanks

Over the years I have had many nearsighted people who have reduced the strength of their glasses. I'll share one story. I met Mary in 1988. Besides being myopic -4.50, she also had astigmatism, i.e. -2.5 to -3.00. The overall effect was -6.5 and -7.00. My first impression was her intense stare. It felt that she glued her look to mine. Mary had worn contacts for 12 years, 16 hours per day. I would say she was addicted. I asked her that question, and the answer was a definite yes. "I pop them in the morning and it is the last thing I take off at night." Mary spent a weekend in a seminar with me, and part of the teaching process involved her to take out her contacts and in a safe place being in her blur. This was very difficult for her because she had to give up control. Yes, looking clearly through

20/20 lenses is a form of maintaining control. This was very challenging for her, because, firstly she had to trust a man, me, who facilitated the process, and then learn to recapture her clearness from the inside. This meant finding her power behind her eyes. I structured process all weekend with patches, working with a partner and modified lens prescriptions, and the participants got in touch with their essence of where vision begins - in their heart. I had them practise breathing, blinking, deep winks, palming for 20 minutes listening to specially chosen music, watching slides and sharing their experiences. On the last evening of the training, Mary slipped on an old pair of glasses (from 7 years before) and she had perfect 20/20. She walked along the beach and for many moments in her naked vision was able to see the ships anchored off in the bay. She even had moments of being able to read their large names. Mary visited another optometrist, on my suggestion, because I usually have a colleague do the measurements, so I am not biasing the findings. The O.D. I use doesn't usually know the educational plan I use to teach my patients. He reduced her nearsightedness to a 20/40 level of seeing. At this stage, Mary simply used her old frames, because I advised her that a further change would happen rather soon. This is my experience with highly motivated patients. Within three months, Mary was no longer wearing her contacts. She took a holiday to Hawaii and wore throwaway contacts while swimming and snorkling of about -4.00. The muscles around her eyes ached during this period as she became aware of the tension she had been carrying for so many years. She used acupressure points to stimulate and relax the nerve pathways to and around her eyes. Combining this with palming, Mary began having flashes of clear eyesight through her weaker glasses which were about -4.5. After about three months, a second reduction in lens power took place. This time I used the approach, I have earlier described in the posting to this group. At this time I personally refracted her and reduced the nearsighted measurement as well as increase the astigmatism component before the right eye only. I also reduced the left eye nearsightedmprescription more than the right to create a patching effect for the left eye. The rationale behind this was to begin stimulating the vertical meridian of the right eye. I knew from my past experience that this would homeopathically open up the withheld emotionality of her past. Please understand that this radical form of lens therapy is only done when I can personally supervise and facilitate the person's journey. This happened. Very soon after Mary received her new glasses, she began to feel a lot of anger, especially toward her father. This actually produced more blurriness through her new glasses and frustrated her. This is the therapy. I coached her to stay with the feelings. At this point I usually have an ongoing commitment from the client that they stay in touch with me. She moved through this phase and about a year later had her first child, a boy. As this young baby became a boy, he challenged his mother. and Mary again, had to face her past perceptions. At about this time, Her prescription was equalized between the eyes again and the nearsighted was reduced further to -3.5 with about -1.5 astigmatism. This was the last time she was to wear an astigmatic component. Mary underwent a course of personal growth at which time she ceremoniously burnt the older glasses. An Optometrist friend, who took the course with her, arranged to have some new glasses made up. A pair of -3.0's for driving, -2.0's for computer use and -1.0's for everything else. This lasted for an additional one and half years. During that time, Mary had a complete clearing with her father, who had earlier sexually abused her, and they became very close. She began to deal more lovingly with her son, and began to look at life from more of a spiritual point of view. It was no longer them and me. Her daily living became us. Mary practised yoga, walking and systematically at this point spent more and more time without glasses. She had a number of positive experiences such as walking down a steep hill and seeing the yellow line marking in the middle of the road extending all the way for one kilometer. Mary was consistently having clear

eyesight. Her visual acuity on a snellen eye test was still below the level of her everyday experience. Her refractive measurements fluctuated between -1.5 and -4.00, depending on her fatigue level and soft focusing ability. The benefits to her visual journey were rewarding. She could now see her husband's eyes at the dinner table without glasses, which were now mainly -1.00's, even for driving during the day. She lives in the country and even drives on sunny days without glasses. When going to movies, she slips on her -3.0's. Mary loves the freedom from where she was in 1988. When I last saw her, a few days ago, I sensed from her attitude that glasses were soon to be a thing of the past.

Status: RO
X-Status:

This was posted to alt.med.vision.improve and sci.med.vision...

* * * *

I got some 20/40 glasses last month. These 20/40 glasses have no astigmatism correction (cylinder) in them. I got this by repeatedly asking for it. I had to go back to the doctor 3 times to get them and the doctor told me that "glasses do not make your vision get worse" but after going back for the third time and telling the doctor that the glasses were too strong I got them. Actually, they were a little weak for 20/40. When testing myself at home, I could not be sure I could have actually read the 20/40 line if I didn't already know what it said, but at least the glasses were not too strong, and I still had my 20/20 glasses anyway, in case I needed them. Next time, I will probably go to a behavioral optometrist, now that I know about them. Thanks Vic.

I have an eye chart on the wall near the TV, and some geometric patterns like a large circle and a big X. I have learned what astigmatism looks like when looking at the circle and the X, so by looking at them, I can see if I have it or not at the time. It is amazing to watch my astigmatism come and go. I thought that I could get rid of my astigmatism by looking at the circle and/or the X and telling myself what they should look like and getting my eyes to adjust so that they look like what they should look like. But it is not so easy. Sometimes it works and sometimes

it doesn't. Sometimes I look at the X and tell myself "this arm should be sharp and black like the other one" and something inside me says, "how do you know for sure. Maybe it is supposed to be fuzzy and gray today." So I get up and walk over to it and see that it is just as thick and black and sharp as the other arm and go sit down again. But that voice inside me is still not fully convinced.

So I go back to watching TV.

After a few weeks of this I noticed something else.

My vision improves when I spend a minute or so looking at a human face. I look at the mouth, one eye, the other eye, and the mouth again, and it gets clearer. After a while, I look at the X and both arms look sharp and black. But if I keep looking at the X one of the arms slowly fades to gray and fuzzy. Hmm...

The voice inside is not sure how the X is supposed to look.

But it knows how a face is supposed to look.

There is no doubt in it's mind how a face is supposed to look.

No internal argument. We both agree. So I spent some more time looking at faces. And I bought some posters at K-Mart of faces. Some cartoon faces with lots of sharp edges, and some attractive women's faces some with nice bodies attached.

I put some on the wall near the TV, and some near my bed.

I woke up this morning over a half hour before my alarm clock rang and spent the time looking at the faces on my bedroom wall without wearing any glasses. They were fuzzy, but I knew they were faces and I know what faces are supposed to look like.

After about a half an hour of this, I put on my 20/40 glasses and read the 20/25 line of my eye chart with each eye alone as well as with both eyes together. I even read some of the characters in the 20/20 line.

If this keeps up, I might go back again and complain that these glasses are too strong.

X-Status:

Howdy People.

Some questions:

1. Where is Vicc? Haven't heard from him in ages...(I hope he did not unsubscribe)

2.

The Background:

Once and for all I have decided to give this eye therapy a serious shot. So far, w/o the aid of the therapist. I have started by using meditation to relax my eyes at night and by trying to ditch my glasses when possible

(ditched my contacts...). I work in front of a computer most of the day.

The Problem:

I notice that w/o my glasses I feel 'stress' (or a tiredness sensation) around my eyes (palming w/cold hands for some secs. helps), by the end of the day my vision is really blurry and I have trouble having conversations w/o my glasses (I like to see who I talk too). I also don't have the best seating posture and look at the keyboard when I type (typing lessons?)

The question:

So what do I do?

Thank!

>

>Glenn Turner

>From what others have posted so far, I gather I'm the most successful user of
this technique (although by now it's MY technique to a great extent, since
I've discovered ways to fight not an abstract myopia but MY myopia, and the
breakthrough came when I realized how much what I'm really up against is
myself).

As for the "real" results--here's what has become real for me after 2 1/2
months:

1. A measurable PERMANENT improvement of about 2,5 D (except for night vision -- I know it's worse but have no figures.)
2. Long periods of measurable improvement by as much as 6D (vision 20/60 -- compare to the original 5/200, or 20/x)
3. Short flashes of 20/30. (I've never had a 20/20 correction and never saw 20/20 under any circumstances.)
4. No plateau yet -- it's getting better every day.

God is the world beautiful!

Elena

This might not be relevant to your question, but amazingly enough, the PCM posts here were more than what could be found in SMV for months. I asked a question on PCM once in that group of so called doctors last year, but noone replied. I can understand if they are not giving vision exercises the time of day, but I can't forgive them for ignoring PCM questions.

Instead I kept reading them saying: contacts and glasses ARE the cure for myopia, beside keratotomy. I guess they must be very scared at the prospect of a non-surgical procedure ending their source of income.

Very disgusting if you ask me. I gave up on the newsgroup long ago.

Sorry, just venting some steam.

Oh, about natural vision improvement. I have let a 'doctor' influence me into giving up on VT when I was in Junior High. From then, my prescription increases from -2.5 to -5.5 on the left, and -3.5 on the right. Despite what my 'doctor' told me, I always tried not to read a book too close anymore. Otherwise my prescription would've been a lot higher.

In October of last year, I was involved in a feverishly busy software project which required near work for 8-10 hrs a day (I am talking looking at a monitor for that amount of time) for a few months. Within a few days, I started noticing that my vision was getting worse and worse (my lenses were not strong enough to see fairly distant objects clearly). I would say that my vision got worse by about -0.5 in two weeks.

I started doing some simple VT. I am happy to report that the same lenses that were not strong enough before is now just right.

I can't really improve much beyond this level.
My problem is that 99.99% of my work is near work (writing software). For now I am settling with maintaining my vision level.
If only I had the time to get undercorrected lenses. Grrrr.

Andy

The claim has been made that Nutra Sweet is responsible for Desert Shield Syndrome. The poster is apparently unaware that considerable amounts of chemical warfare were practiced against the troops involved in that action. This has now been well documented. Additionally, a number of nuclear plants were bombed and the nuclear material was released to the environment. Hence there are many other probable causes for Desert Shield Syndrome.

Various mechanisms have been suggested as the precipitating cause for myopia. These include dishonesty, sexual dysfunction, suppressed anger and several other mechanisms. Consideration of the Yerkes-Dodson Law tells us that performance in an individual increases with levels of stress up to a certain point. Beyond that point, increasing levels of stress reduce performance. Perhaps myopia results from overstress. The methods that are effective in reducing myopia are in general connected with relaxing the eye. Perhaps relaxation in general will serve to aid in reducing myopia. For instance, is there a connection between meditation and improved vision?

Eyeglasses serve secondarily useful purposes in addition to "sharpening" vision. They protect the eyes from wind and debris. They also protect the eyes from ultraviolet radiation which has been shown to form cataracts. Note that most of the UV radiation that gets past eyeglasses enters through the top of the glasses. Hence, when choosing sunglasses, be sure to get a pair that has a tight fit between the top of the glasses and the bridge of the nose and eyebrow region.

This group has been most useful to me in reminding and encouraging me that eye improvement works. I spent a considerable amount of effort a few years ago improving my vision with the Bates method. Then I allowed myself to be discouraged from continuing by a rather mediocre optometrist who viciously attacked the concept. I am now slowly getting back into the "swing" of things.

The hints about a burning sensation connected with clear flashes were quite valuable to me. I have noticed the same effect, and had been attributing it to allergies. Now I know to recognize and seek that sensation. Also the hint about holding a book as far from my eyes as possible is excellent advice.

I am operating on a low budget and cannot afford to go through new sets of glasses as an aid to vision improvement. Since I already have a set of computer glasses, I have taken to wearing them when I walk around the house and go outside. I have found that when I apply some of the vision improvement methods at the same time, this approach works quite well and I can read signs at a distance and also get some "clear flashes".

Robert

Hello Florian:

I was blown away by your honest assessment of your visual and other predicament. On the other hand, I wanted to share some of my personal experiences which could make a difference to you, and your eyesight, if you were courageous enough to risk stepping out of your safety zone.

I have been undertaking a personal vision and professional training in improving my vision with Robert-Michael Kaplan, a behavioural optometrist, here in Canada, who directs Beyond 2020 Vision=81, where I am currently apprenticing and working.

Last year, I visited his practise as a patient, because I had worn the same lens prescription for the past 18 years, for driving, shopping and movies. My vision began to deteriorate even further, and my right eye felt like it was turning outward. I was worried and panicky that I would become dependent on glasses and my eyesight would worsen further.

Within a few months of doing Dr Kaplan's prescribed vision therapy, I no longer wore my eyeglasses, even for night driving!!!!!!! It sounds like you are in a very desperate situation, and in my humble opinion, you have

some important lifestyle decisions to make regarding your well being and eyes.

I have tried many therapies during the last few years, and integrated vision therapy has been the most powerful in depth and profound in simplicity.

If I might be so bold as to recommend something for you, I would heartily encourage you to visit with Dr. Kaplan, who is lecturing in London, England between September 25th and October 11th, 1995 for a couple of one hour personal consultations.

If you would like to discuss this with me further, please e-mail me at Beyond_20/20@sunshine.net. Also, request more information if you like.

Sincerely,

Kim Tasa.

Subject: Elena on her permanent improvement (at length)
Status: RO
X-Status:

I started planning this post a week ago and discovered there's just too much I want to say! I'll have to try to curb myself and, in describing my methods, skip over many a "why" and summarize some of the "how"s in the end -- so in case you get bored or unconvinced by my rendition of the "why"s just skip to the last portion of the post. I am very grateful to everyone who has helped me along the way with numerous tips and ideas and reference sources -- and I am grateful for this opportunity to discuss the subject I've become fascinated with. For the past few weeks, I've been accused by my family of "talking nothing but physiological, linear, and quantum optics." Among my friends, I probably rank as a one-subject bore by now. I used to be a sharp conversationalist; these days, no matter what is being discussed, when someone asks me, "What do you think?", the answer they are likely to get is, "I think that cloud over there looks like an overweight Dalmatian, and the one to the left is a portrait of Karl Marx, only the beard is better-groomed than in the original." Or, on a sign-reading spell, I will contribute to the general conversation by declaring, in the tone of a celestial revelation, that "this swimming pool is not required by state law to have a lifeguard on duty!!!" Recently I've also had to suffer through being introduced to people in the following manner: "This is Elena; don't pay any attention to her, she slips into a meditative trance every five minutes and isn't really there."

This is the price I have to pay for my new visual awareness: I'm as engrossed in what I'm doing and as removed from my immediate surroundings as SOMEONE READING A BOOK; only this book happens to be spread all around me, in all directions and at all distances. Otherwise, the attitude is the same: I don't skip words or sentences or paragraphs, and I don't welcome interruptions.

I think the key is paying attention to what/how you see AT ALL TIMES. Of course glasses should be removed from the picture, except for the situations

where seeing the world the way you see it is life-threatening, like when you're driving. For all other purposes, watch your real world. Try to understand and appreciate the fact that your blurry world is MORE real than the world of an emmetrope, closer to the truth, closer to what it physically is. A perfect world of emmetropic vision is a hoax. Nobody's eye is an object of perfect optics, and everyone's picture on the retina is blurry.

The emmetropic brain selectively enhances the signals from the center of an image and suppresses the ones from the periphery, thereby getting rid of such REAL phenomena as light interference and diffraction; that's how emmetropic high contrasts and sharp lines are created -- by eliminating the unwanted parts of reality from perception. A myope loses (or, more likely, forfeits) this ability to fool himself, to adorn the picture of the world this way.

Far from being dishonest, we are being honest even in our perception! Far from being conformists accepting the hoax of what everyone else agrees to see as "reality," we see a more real reality. Our blur is created by the laws of physics some of which we alone can observe directly. Lift up your head in pride, o ye myope: you see the world closer to the way God sees it.

Myopia is not a disease: it's a disagreement, a dispute, a dissatisfaction.

It's dissidence. It is, to use a very unscientific term, unhappiness. Well -- do any of you have serious reasons to believe that human condition has nothing in it to be unhappy about? Were it so, were we the ones who rain on everybody's parade by refusing to see just how perfect the world is, we would have to be ashamed of being myopic, and rightfully jammed into glasses through which the party line can be seen so clearly. But I feel that we are simply the ones who have more sensitivity, emotionally and intellectually, to the world's (and our own) sorrows -- and when it becomes unbearable we shut it down indiscriminately (because we don't know how to shut it down selectively). All of it. The higher the myopia, the more drastic the conflicts must have been that had found their only "resolution" in one's failing to see them!

The difference between failing to see and choosing to ignore may be very obvious on the conscious level, but on a deeper, unconscious level of perception, it disappears. I happen to have a very good example handy, where the organ "choosing to fail" is not the eye but the principle is the same.

In the Russian émigré community whence many of my acquaintances come, I have often observed numerous cases of temporary hearing impairment whenever an unfamiliar English word or expression was used by a native speaker conversing with one of my friends whose English is less than perfect. These people, well-educated professionals accustomed to high levels of cognitive success in their native tongue, and highly frustrated by their -- average at best -- cognitive performance in a second language, didn't realize in such situations that they'd failed to understand something: instead, they simply "didn't hear." Later they would often insist that a given subject was never discussed at all. They were not aware of having missed something -- instead, they were restricted in their awareness to what they didn't miss. Everything else was not consciously ignored but unconsciously omitted, not merely from cognition but from sheer physical perception.

Here's another striking example -- of how much the way we see is our protection against... God knows what, it must be different in every separate case -- and in this particular case, something quite dramatic. A close friend of mine who is a psychiatrist, a myope totally dependent on glasses, and a hard-core skeptical thinker who utilizes nothing but an extremely non-permissive scientific logic in any discussion, was recently asked to evaluate a patient admitted to the hospital. The patient, a beautiful woman in her thirties, had recently had her high myopia corrected by laser. She had always considered her myopia "a curse" and dwelled on the opportunities she had supposedly missed because of it. The correction had given her a perfect 20/20 vision and involved no unusual side effects or complications.

Two months later, she was hospitalized with acute psychosis; she has no previous history of mental illness. Her present problem is, she is not only clinically depressed but absolutely incapable of functioning in any way because she refuses to open her eyes. She says that she doesn't want to see the world with her new vision, that getting it was "a terrible mistake," and begs the doctors to give her back her myopia. I must say that if this patient didn't exist I should have invented her because she really helped me to get my friend interested in discussing possible psychological aspects of myopia with me, something she never bothered to consider before. I have her roaming around with no glasses on now, and meditating, too! But of course the best part is, now her knowledge is applicable to my hypothesizing, and I can count on her for weeding out my wildest speculations while expanding and sustaining whatever is plausible.

Zarin, you wrote you would be convinced with "real" changes in the eye, while what you have observed in a clear flash was just blur reinterpretation. I happened to be reading "Zen And the Art of Motorcycle Maintenance" just alongside all the books on vision improvement, so every time I encountered the word "real" it would trigger a number of intellectual reflexes contracted from reading that remarkable book. What is real? An emmetrope's reality is constructed by the brain as much as a myope's reality -- even more so, considering the emmetropic brain has to eliminate a greater number of "real" light phenomena like interference and diffraction before it gets its picture right. Inasmuch as through vision, we are all dealing with mental images of objects, not objects themselves, none are "real" or all of them are "real" -- it really doesn't matter. The real "real" is electrons and protons and quanta -- something we never see anyway. I've always preferred avoiding my glasses -- just using them when necessary, like any device, never living in them -- because to me, they represented a mechanical distortion of MY reality, however different the latter may have been from everybody else's reality. I'm used, cognitionwise, to something everyone on this planet has to deal with, whether they ever give it a second thought or not: to having no immediate access to anything more real than my mind's choice of reality -- forever relative, be it myopic or emmetropic. At some point in the past (specifically, when I was 13 -- which, incidentally, is the prevalent age in females for the onset of myopia), my mind had chosen, or was forced to choose, to interpret the incoming data in a fuzzy way. To do this efficiently and with minimum monitoring, it had to do something to the eyes; it was done anatomically, organically, functionally, or through all of the above. The important thing is, however, that it couldn't have been done without a direct command from the mind, and can be undone by the mind's alternative decision, by its choice of a different reality, a different mode of perception/processing. The very first clear flash was enough to persuade me that it can be done, and I don't really have to know what it is exactly that my eyes are doing to obey this command, any more than I have to monitor my liver in order for it to dispose of the toxins properly. Extrinsic muscles or the ciliary, the curvature of the lens or the saccadic movements -- who cares? (Ophthalmologists should but they don't.) Eyes are there to look pretty, is all. The important thing happens inside my head, and to say that it's a "mere" reinterpretation may be perfectly correct -- if we eliminate the "mere" part. It's a reinterpretation of reality, a choice of an alternative universe, for God's sake! What can be less "mere" than that?!

Besides, I'm sure that "real" changes in the focusing mechanism do occur in the eye itself. (Otherwise, why the burning and stinging and the tears? How can these purely physical symptoms be accounted for if the eye itself is doing nothing?) Someone with -4D may be able to reinterpret the blur; with -8D, however, there's nothing there to reinterpret: I don't know the street sign exists, let alone interpret what's written on it. With me, it's not the case of something that

can be seen somewhat better -- it's all or nothing (nothing in terms of everybody else's emmetropic world, not in terms of my own world -- but they have little in common). At least that's how my clear flashes started. Now it's seldom "nothing" because my vision is constantly better, but still, at around

-5,5D, screwed up enough for me to appreciate the difference (in and out of a clear flash), and believe me -- you would have to reinterpret oxygen and learn how to breathe under water to get this amount of difference between the two worlds.

Today I want to live in the clear world, not because it is in any way superior to my old blurry world, but because it's a lot easier to use a world well broken in (like an old shoe), a world designed by generations of my predecessors for emmetropic use, than to cultivate my -8D (Minus Eight Dimensions!) universe which nobody can comprehend or share with me, or make more comfortable or safe. (Surely it's not the world where they would have invented driving! But things like fuzzy logic would thrive there and technology based on it can be superior to anything dualistic logic has produced -- the Tokyo-Osaka express has already shown it!) My world is NOT defective; it's just that the rest of this planet won't have anything to do with it; so I have to live where they all live, or be alone in my universe.

Well -- I've made my choice. Whatever decisions my mind has made in the past in order to avoid the perils of living in the artificially clear world of emmetropic vision will have to be void. I will never tell my mind that they were bad or wrong decisions; on the contrary, I will admire its ability to find this relatively harmless way to metaphorically express the inner conflicts so profound that in order to navigate through them without getting me into some chronically diseased state, without killing off my curiosity and imagination, and without turning me into a bitch, it had to do SOMETHING and had chosen to dim the harshness of the world on my feelings as best it could.

But today I'm encouraging it to turn it all on to full blast. I am strong; I can cope; I don't need any analgesics for the pain of living in the world I have to share with billions of creatures unlike me. I can take it.

With this attitude in mind -- now for some practical recommendations from my experience.

1. Some exercises usually practiced for vision improvement are boring. Don't do the ones you find boring.

2. Watch your visual perception AT ALL TIMES. Trace, blink, breathe, do whatever you remember to do -- but decide to dedicate a portion of your life (say, a month... a week's vacation if a month sounds like too much) to forming this habit. I know it sounds boring... but if you tell yourself there's a time limit and you won't have to do it beyond this time limit, you'll be able to talk yourself into trying. (I predict you won't be able to stop afterwards, but that's another story.)

3. Vision is passive. Attention is active. Never ever mix them up! It's a very myopic thing to do. Don't choose what you want to see, it's your eyes' choice. Don't ever forget to pay attention to whatever they choose to see.

A dot, a spot, a line, a letter -- if your eyes have singled it out freely, pay attention! If they lose interest and go somewhere else, follow them with your attention (not vice versa! Don't make your eyes follow your attention!)

4. Watch every sunset like a special effects show designed with the sole purpose of impressing the single important spectator -- you. Look at every natural phenomenon this way. Look at as many as you can this way. Become the center of the universe, the one for whom the sky changes its color and the ocean brings its waves closer for observation and approval. Ascribe the eyes of an adoring puppy to the moon: all it wants to do is look you in the eyes with eager anticipation of attention. Find thousands of such eager eyes among the leaves of every tree.

5. Learn to write with your left hand. It will greatly stimulate your right

(visual) brain, often idle in myopes. Don't try to imitate your right hand's writing or you will feel totally helpless: your left hand can't do that, but it has a hidden OWN handwriting that has nothing in common with that of your right hand. Experiment and discover it. Don't force it to write in the correct direction -- it often prefers mirror reversions of letters, doesn't care whether it's writing from left to right or right to left, and might even like to write in a circle or a spiral rather than a straight line.

6. Become a junkie for light. Mentally direct it from its every source right into your visual cortex. Thunderstorms are great: let every lightning enter your head and explode with light inside your brain! When lightnings are not available, make use of whatever is flashing: police cars, fire engines... The sound should be transformed into light, too, and blast right into your visual cortex with the power of a hurricane!

7. Rewrite every scene from your past you are not particularly proud of or happy about. Create an alternative, more satisfying memory of this scene inside your head. Delete and overwrite the first script. Let it happen the way it should have happened. Tip: use violence where you were intimidated, arrogance where you were shy, courage where you were a coward; be a perpetrator where you were a victim. Perceive yourself as STRONG.

7. Make eternal peace with who you are. Justify yourself to yourself.

Justify your every action and emotion. Discover your innermost motives; discover how perfectly necessary and valid and instinctively right they've always been!

8. Establish an imaginary attention point in front of you, a point where a V projected from your eyes narrows down to an invisible dot in space. The angle of the V is wider at short distances, and extremely narrow at great distances. Then forget the V and be aware of just this point of attention wherever you move it. Place it on top of an object and simultaneously move the object down with this power point. Place it under the object, pushing the object up. Apply it to the left side of the object and push it to the right, then vice versa. Watch the power of your attention point move objects in space. Far and near, great and small, they all move wherever you push them.

8. Choose three objects lined horizontally in front of you (in your blur zone) on the same line of vision. Look at the central one while maintaining peripheral awareness of the other two. Don't try to get rid of weird light/dimness effects, pulsations, etc., that you might observe this way.

Blink very lightly when your eyes begin to burn -- and enjoy the clarity!

Remember the sensation. Eventually you'll be able to re-create your clear flash by just imagining this sensation whenever you choose, and later to maintain it.

9. The struggle with myopia is the struggle for control. If you go on living in a body that's totally beyond your mental control, something else will eventually go wrong, given the appropriate genetic/environmental opportunity.

Winning over one malfunction provides you with confidence and skills to fight any disease that may be lurking in the dark of the future. I don't think this struggle for control has been initiated by my conscious self: I think it's my survival instinct that does my blinking and tracing for me.

Hence my last recommendation: treat your visual activities as a quest for survival. You won't have to question their validity with this attitude.

Treat them as the most important part of your life, as its center rather than a mere aspect. Let everything ride on this attitude. Trace your thoughts; give them geometrical shapes. Paint your sex crimson and purple and neon red. Outline your anger, watch it turn into a deadly arrow, shoot it through the heart of your enemy. Draw your love, make it into a weightless, shimmering cover to throw on your loved one's shoulders. Crown your friends with rainbows around their heads. Stroke every cat with your eyes, and every dog. Visually recreate the process that has made a seed grow into a tree.

Elena

For every complex problem,
there's a simple solution,
and it's wrong.

X-Status:

Hi, :-)

I'm new to this list (Alex Eulenberg and Jim H Day may remember me from a Sci.Med.Vision-thread about myopia).

Anyway, In 1,5 years my eyes have become more myopic, 1,5 years ago they were about -0.5 dpt., now they're -2.25 dpt.

I've been to an eye-doctor who said that reading and close-work doesn't have anything to do with the myopia.

I have learnt from various sources that some of you out there doubt that.

I would like to know more about the "alternative" way of approaching the myopia-thing.

1) I have read about "Palming" on the net, but it seems just too simple, does ot really work the I think it does ? (cover eyes, relax)

2) Also I plan not to wear my glasses during close-work.

Anyway, I would love to hear more of these "easy to apply yourself" tips, I don't want to become more myopic.

A few more question(s).

My eye-doctor told me that I have "high eye-pressure". (He said "19")

As far as a I know normal pressure is 16 +/- 5.

There is no glaucoma in my family, does this mean I ****just have high ocular pressure**** and that's it ?

Will palming be able to reduce this (the eye-pressure) ?

Or anything else (besides the standard medicines and operations) ?

All info is welcome,
Greetings,

Jerry.

ps. For those concerned, I visit my Eye-doc each 6 months.

pps. The fact that I have "high eye-pressure" was only discovered by coincidence because I was becoming a bit myopic a year ago..

Subject: Documented Myopia Reduction
Status: RO
X-Status:

On sci.med.vision, In article <4alsj0\$gls@ixnews5.ix.netcom.com>,
Paul Harris <babo@ix.netcom.com> wrote:

>Two articles in a recent (within the past year) Journal of Behavioral
>Optometry were written by OD's are their personal stories of myopia and
>myopia control. One woman went through a long term 8-10 years worth,
>of work, (mostly on her own with infrequent periodic visits to OD's)
>and made a 5 diopter shift. The man made about a 4 diopter shift.

Just filling in the facts here...

I don't know which man Dr. Harris is talking about, but one woman,
Antonia Orfield (OD) wrote an article in the 1994 Journal of Behavioral
Optometry entitled "Seeing Space: Undergoing Brain re-programming to
Reduce Myopia" (pp. 123-131). It was not a five diopter
shift, but still significant. From the abstract:

* * *

:The author underwent myopia reduction from a spectacle prescription of
:-3.87 DS and -3.37 DS to -.50 DS and -.25 DS over a period of seven
:years. The essence of the program was passive adaptation to a series of
:weaker glasses and better vision in a reverse of the process of adaptation
:to stronger and stronger glasses and a more and more warped
:space world...

* * *

>From the article:

* * *

:My training consisted of three phases.

:First Phase, 1975-1981: Lens reduction without any specific training
:techniques until I wore a -1.50 DS [diopters] and -1.25 DS spherical
:prescription. Prior to '75 I wore a -3.87 DS and -3.37 DS with a small
:amount of against the rule cylinder. That Rx was based on a cycloplegic
:refraction in 1973 that had already cut me from my old -4.25 DS with
:cylinder OU [both eyes] prescription.

:Second Phase, 1981-82: Office training with [Dr. Amiel] Francke [in
:Washington, DC] for two three-month blocks of two one-hour sessions per
:week, with one month free between, and two months of a home program
:after. This took me down to what I now wear for good distance vision
:(-.50 DS and -.25 DS in spin-case soft contact lenses). These lens
:powers were determined by retinoscopy, as well as the subjective
:refraction. When I left Washington, I was also wearing a +.25 DS pair of
:training spectacles over my contacts for walks, and getting excellent
:vision most days. During that year every lens cut was first practiced
:with plus spectacles cancelling out minus before I actually received new
:contacts. Even with no lenses at all, I was comfortable at the beach
:that summer, seeing numbers on the sailboats, addresses on the houses
:across the street, white caps on the bay.

:Third Phase, 1983-89: Further Rx reduction with [Dr. James] Blumenthal
:[of the Illinois College of Optometry] in Chicago to a -.25 DS and a
:Plano, and then a struggle to hold my gains. For six months I wore
:nothing on either eye except to read. There followed a private tutorial
:with Blumenthal on myopia control during two years of pre-optometry
:classes and four years at ICO. My vision held up fairly well throug the
:first year and a half of optometry studies. Then there was some slippage
:in spite of our efforts, but now I am back to where I was when I left
:Washington. This phase involved no actual vision training, just lens control.

[...]

:Since I have learned to SEE SPACE, a -2.00 flipper reveals a visibly
:flat and warped distance view. A -3.50 DS or a -4.00 DS is a swimming
:blur, the way my father's glasses seemed to me when I was a child. It is
:hard to believe I spent years looking through them. How was it possible?

:By gradual, stealthy adaptation.

:How did I get out of them, then?

:By gradual de-adaptation.

* * *

--Alex

Subject: Vision Quest, step 1.
Date: Mon, 4 Dec 95 10:19:28 MST
Status: RO
X-Status:

Greetings,

On the first major step of my "Vision Quest" (eyesight improvement, at least), I plan to confront my optometrist (glently ;) and ask alot of questions and tell him of my intentions to try and break my dependence from glasses. I am mainly going to ask if he will help me to gradually reduce my prescription of my glasses and maybe my contacts. Though, I've gotten the feeling that glasses may be better because you don't have something in your eye which might interfere with your eye shape directly.

Any suggestions about what/how I should approach him? What else to ask? Should I just go to using glasses and no contacts? I wish I could go cold turkey off of my glasses, but I work with computers and this makes it nearly impossible to do.

Suggestions are appreciated,

M.A.T.

X-Status:

Hello all,

I am new to this list. I am a graphic illustrator, designer, coordinator and an energy field therapist (Reiki Master, completed Healing Touch Program, Therapeutic Touch and currently a student at Barbara Brennan School of Healing). I am familiar to some degree with natural vision healing but do not know the details. I do know that I do not agree with my optometrist (closed and rigid) and my eyesight fluctuates greatly (I am very near sighted, astigmatic, and have had reading glasses for a year or two which I use sometimes...sometimes I dont need them...I wear contacts. I was in bed for two weeks last year recovering from orthopaedic surgery on both feet and not wearing my contacts. I totally lost the need for reading glasses. I called my opt. and asked him what was going on...he said, "thats right...that happens..." . You would think that perhaps I might have been told that discontinuing contact lens use would prevent reading glasses...anyway...he believes there is no REAL improvement possible. He says once the eyes start to fail, it only gets worse. I told him I do not agree but I dont know where to start...walking around with 20/200 vision turns me into a super-introvert and I walk around looking at the floor. I hope there are optometrists on this list as well as none-optometric holistic people so I can get a well rounded view (no pun intended) of my situation. Any comments/recommendations would be appreciated.

Thank you.

Marla in Birmingham, AL

>Mark Jensen

I think it's not a bad idea to have Bill here -- long as he refrains from insulting anyone sci.med.vision-style.

There definitely are eye problems in this world best dealt with by orthodox ophthalmology, even though myopia is not one of them. I'm sure we can learn stuff from Bill -- provided learning goes both ways!

Bill -- I remember a post about a bet of sorts, I forget the details but I remember the figure -- a thousand bucks. Who were you going to pay? Can I get a piece of that pie if I prove to you that I've improved my high myopia?

You could get my medical records from my respectable Park Avenue ophthalmologist whom I have visited for the last time a few years ago. I didn't know anything about natural vision improvement till June of this year -- I have copies of my original post asking for information and Alex and Vic's replies. So I've been in "self-training" for six months. I started

from ground zero -- I couldn't read the first line at 5 feet. Today I can read four lines at 20 feet, and more on a good day -- up to 20/50. Because my vision now fluctuates constantly, I would prefer to wait a few more months before subjecting myself to a formal test (I'm prone to stage fright).

But since the stability of my better vision continues to increase, I believe I could show you quite impressive results in a while.

Oh -- and I only wear glasses for driving and unfamiliar surroundings now.

Can you imagine?! Never felt better in my entire adult life: headaches, eyestrain, etc. are the thing of the past. Haven't taken a painkiller in six months. I wonder how you could measure things like these.

Respectfully,

Elena

Elena - this is exciting to read. What did you find the most effective tools, exercises, etc - ie how did you do this? I'm just getting started, actually I'm at the 'is this really possible ? sounds like a dream come true - how do I do this' stage. My eyes are currently at -4.50 I would LOVE to be able to take my glasses off, and the headaches are telling me it's time to do *something*.

This is a great article! Thanks for sharing it.

At the bottom he mentions a 3-d wallpaper for a PC - is this available anywhere ?

Thanks
Alice

ps - I went to my Dr. yesterday and got glasses at -3.50 (was wearing -4.50) - he has never worked this path with anyone, but is interested and willing to persue it with me . . so the adventure starts!

thats a 25% improvement. I finally got around to returning to my old optometrist, to get a "full" prescription, since I actually dont have one. I am going away for xmas and while I can drive around on 20/40 script on familliar roads at night, I dont feel comforatble driving out in the country at high speeds on strange roads. the whole thing was a last minute decision, and I didnt prepare for the examination at all. I knew I had gone backwards a bit in recent months, too many hours in front of a computer, but I was surprised that I hadnt reverted back to my old script of -2.25. what I should really be doing is getting back into a serious regimen of VT, which I keep putting off.

anyway I didnt tell the optometrist I had been doing VT and went in complaining about headaches, which was true a year ago, so I wouldnt have to explain why I wasnt wearing my glasses. As per usual no cyclopegics, I have never had one. autorefraction and the usual health test, eye pressure. and then the subjective refraction.

I couldnt really tell much difference between a lot of the lenses she made look through, so I suspect she was hovering around where she expected my Rx to be. then she checked my near vision. which I know has also improved as measured by my behavioral optometrist.

she double checked my records did some more tests and finally she announced that I wouldnt need a stronger script(was -2.25 x -1) and in fact I needed a "slightly" weaker script (-1.75 x -.75) and then proceeded to sell me on the idea of getting weaker glasses. (like I needed any selling) seems almost everybody comes in expecting more "power". she didnt ask me why my vision had improved, although she was surprised when I told her originally that I didnt wear them wandering around. seems if you are -2.25 x -1 then you cant walk around without glasses. which I found very difficult when I first tried it. but now I can see the eyes of passers by and even read parking signs.

the script she gave me I call my base vision. which is the norm, the not really trying to see grove, I also have another groove I fall into every now and then where things are much clearer. I suspect maybe 10% of day I can see close to 20/20 without any lenses. there is a bit of edge "pluming" probably from astigamtism. but it seems the sphere is quite willing to revert to 20/20.

now during the same year the other 3 guys in my office, also all over 30, have had increases in power. not surprisng considering how much time we spend staring at computers.

so hey doc Stacy do I qualify for some of that cash? you can have access to my records for the last 5 years from the same optometrist.

I have heard the usual stories about people making good progress and then when they stop they slip back to as bad or worse then they started, so I am encouraged that having done nothing VT like for nearly half the year I havnt sliped back very far at all. probably no more than -.25. I am certainly encouraged enough to start doing it all again and aim for another lower plateaux.

Vic

Subject: Elena tells all (long)
Status: RO
X-Status:

Hi everybody,

here I go again.

My approach so far consisted in:

- 1) reading all the books on the subject that two dozen local libraries could produce;
- 2) trying to assess all possible emotional, behavioral, psychological, intellectual, cultural roots and consequences of myopia;
- 3) experimenting with many Batesean techniques and inventing some of my own;
- 4) removing contacts forever and avoiding glasses most of the time (while owning three pairs none of which is a full correction);
- 5) using yoga, meditation, visualization;
- 6) taking many vitamins and supplements (after thoroughly researching the subject) and some herbs.

IMHO, the key to success is to think your myopia through and through, to understand its exact place and role in your psychological makeup. If you perceive yourself as a malfunctioning robot you might benefit from treating myopia as a technical problem; but if you're pretty sure you're human, you are more likely to succeed if you understand it as an outcome of any number of psychological/physiological events, some independent and some intertwined, synergetic, linked in cause/effect loops, vicious circles, etc., etc.. I consider trying to dig out all possible roots of the evil a very important part of the process (at least in the case of high myopia, which is the only case I had a chance to study thoroughly from the inside). I devoted my previous (September) post to some speculations around this idea (to convey everything I came to believe and understand in the past few months, I would have to write a book.) This time, however, I'll try to stick to describing some of my practical techniques, since that's probably what you'll be looking for. However, I should emphasize that, to me, separating "practical" and "theoretical," physiological and psychological, seems rather counterproductive. As one Nobel-prize physicist converted to Taoism once said referring to his understanding of the workings of our whole universe, "it's all mind-stuff." While I'm neither a physicist nor a Taoist, I find the concept appealing and have been trying to apply it to my personal case.

The techniques I'll describe are not the only ones I use, but I've been more successful with them than with the "generic" ones. As for nutrition,

vitamins, etc., I don't know if I'm a better expert than the next guy/gal, so I leave it out. Everyone is welcome to ask questions, and I'll be grateful for any feedback. I have also included an appendix -- a little case history so you can evaluate and compare some of my myopic experiences with your own.

(Nearly everyone's vision will compare favorably with mine, so you'll get an additional reason to expect success in your case.)

I've benefited greatly from visualization and meditation. I experimented a lot and learned to combine the two. Before I started VT, I only had a passing interest in meditation and a very brief experience; what told me to look further was a striking similarity of my purely physiological responses to meditation and to some Batesesean techniques. Those are all rather subtle sensations, but they are signs of deep relaxation and can't be mistaken for anything else once you've learned to recognize them. I decided to look for images that would work best as triggers of this state. I think those images have to be very personal -- again, no generics -- so you can't really benefit from mine, but I'll give you an example that may help you find your own.

I have extremely clear early childhood recollections, not only of significant events but of virtually everything (before I became myopic I had photographic memory). At four years of age, I once picked up a tiny black stone shaped as a perfect sphere. I remember holding it in my palm, finding it pretty exciting, and wondering what the purpose of such perfection on such a small scale could possibly be. I couldn't even show it to other kids or my parents because it was too small for them to pay any attention. Now, Bates-instructed, I was searching for a perfect black object to remember, and immediately retrieved the image of that stone and mentally answered the question of the four-year-old about its purpose: to be remembered, over three decades later, as an example of how incredibly well you (we? I?) can SEE, my dear! Now the perfect black is represented to me by a tiny spherical speck in my own four-year-old palm, and meditation on this object takes me back in time. I open my eyes and, at least for a while, see as clearly as in my childhood.

I've been practicing "the art of blinking" a lot, experimenting with different techniques and combining them with short, "instant" visualizations.

I've learned to blink very lightly to avoid a painful clear flash (when my clear flashes just started they were accompanied by a lot of pain and tearing -- a sensation of an unbearably bright light and some onion juice in my eyes). I have developed a different blink to instantly start a clear flash (works 90% of the time) -- I keep my eyes closed a split second longer than in an ordinary blink and imagine pushing the eyeballs backward and a little downward with the insides of my lids, then open them as though my lids are operated by very soft springs. A note for females: I find some useful blinking techniques incompatible with mascara (the upper and lower eyelashes tend to stick together). Excessive tearing in the beginning may also be a problem, so stick to waterproofs or better do without for a while.

I took up some yoga. After a yoga workout, I lie down flatly on my back and, with my eyes closed, imagine the eyeballs in a free-fall inside my skull, all the way to the back of my head. After this visualization, everything looks maybe a bit smaller (like through the glasses) and a lot more distinct; the relaxation value is unmatched.

When I do a Buddhist meditation (with attention on your breath), I imagine breathing in and out through my closed eyes as if they were nostrils, or in through my eyes and out through the back of my head, or in through the nose and out through the eyes. When I do a Dzogchen meditation, for which you are supposed to keep your eyes open, I do it in front of the Snellen eye chart and "put my awareness into my eyes."

I take regular walks with the specific purpose of looking into the distance.

(No glasses of course!) I visualize a lot while I walk, constantly imagining all kinds of weird thing. My eyes floating freely above in the sky, looking downward with excited curiosity. The earth being rotated backward by my stepping feet, as if I literally walk on the surface of a giant ball. The space and time changing places, as if I'm exercising free will in choosing my direction of movement in time but am being dragged along involuntarily through space. I don't stick to one particular visualization -- I invent them on the move and change frequently. I get my best vision this way.

I've tried self-hypnosis. I wrote down a list of key words and phrases that I associate with the idea of perfect vision, and then incorporated them in a suggestion in the form of a page-long rhythmic poem. I did it because I suspect that anything rhythmic has a better chance of reaching the unconscious. I repeat it to myself when I start falling asleep at night.

(Sorry I can't share it with you -- I wrote it in Russian, because it's the only language I knew when my vision was good, so I keep in mind that the deep unconscious memory levels I'm trying to reach might not understand any English.)

I use 3-D pictures to practice convergence and divergence. I got them from a \$3.50 children's book, "Eye Illusions," which I accidentally came accross in a drugstore (while doing my shopping without glasses...). I have six of them mounted on the wall near my computer.

Appendix: A little case history.

I had perfect vision as a kid, and a coincidental photographic memory which made any type of learning a piece of cake -- and which was totally obliterated after a couple of years of big-time myopia. I started reading at 3, and was through with children's books and meticulously going through my parents' library by the age of 5. My paternal grandmother was a -18D myope; however, my parents, now presbyopic, were both 20/10 till their late forties.

At 10, I had a routine vision exam at school, and the doctor told me I needed glasses and gave me a note for my parents. I flushed the note down the toilet and lived happily... not ever after, unfortunately, but for three more years.

At 13, I noticed for the first time that something indeed might be wrong with my vision: things started to disappear form the chalkboard. For a few months, I dealt with the problem by having other kids copy stuff from the chalkboard into my notebook. (In the alcohol-drenched Ukrainian miners' neighborhood of my childhood, my peers were tough, anti-intellectual, and anti-Semitic; I had fought my way to acceptance and respect in numerous and merciless fist fights I got into at the slightest provocation and on very short notice, even though I was a Jewish intellectual and a skinny girl.

Glasses would certainly interfere with this image of a fierce Amazon warrior I had cultivated myself into out of necessity.) Sometimes I could still see the chalkboard myself -- it all depended on the lighting, the mood, the subject... Finally I gave up and went in for an eye exam.

I have no idea how it is done here, but where I lived, ten to fourteen days of cycloplegia were a standard measure before you got your first Rx for myopia. They made a big deal out of differentiating between an "accommodation spasm" and "genuine" myopia. If the minus Ds were low they sometimes prescribed plus lenses for close work, along with the minus for distance. If higher they sometimes prescribed vision therapy. Yes -- in the Soviet Union, in 1970, an ophthalmologist prescribed VT. I went in for it for a month or two and improved, then quit it and relapsed. They didn't

explain what could be done at home on my own, and aimed the in-office training only at the accommodation spasm, so they didn't "go all the way" either. Yet, as a side note, I should mention that when I first came to the U.S. six years ago, the biggest jolt of the infamous cultural shock was delivered by seeing the sheer number of people wearing glasses.

Anyway, my VERY FIRST Rx was OS -3,25, OD -3,5. Which probably means that I had a high adaptability to under- and no correction right from the start.

Even as my vision reached -8D over the next 25 years, I've never become addicted to glasses. I could always walk, talk, eat, cook, swim, dance, listen to the music, and of course read without glasses. (I did get a -2,5D pair for reading at some point, but I started using it only a few years ago.

I now use it for computer work and the TV, and once again I don't need any correction for reading.) Removing my glasses had always been my automatic response to any situation which didn't absolutely demand that I have visual control over it. I never felt OK wearing glasses, never had a comfortable pair, got headaches and eye irritation from contacts, couldn't take full correction at all (my head and my eyes felt like they were about to explode the second I tried it), and my vision ALWAYS took a plunge whenever I had to spend long hours every day wearing glasses without a chance to utilize my normal "on and off" routine. The plunge was always sudden rather than gradual (two to six weeks was all it took to get an extra half or full diopter), so there's no doubt in my mind as to this pattern. As for the amount of close work, it has always been approximately the same and always extensive.

Whenever I came to a doctor complaining that I couldn't see zilch in my latest pair of glasses anymore, I wound up with a stronger prescription and a comment that, "fortunately," I had "very healthy eyes." That was nice to know, of course, but I always stumbled at the logical block a designation of my eyes as "healthy although myopic" created in my mind. Surely no one would call "healthy" a pair of legs that couldn't walk? ...Unless of course the key was the controls. The mind, or the brain, or both. Someone who is paralyzed due to a stroke might have healthy but useless legs.

That was the first inkling of the idea that whatever is wrong with my vision might lie somewhere deeper than the organ itself. But before my first reading of Bates, I couldn't make heads or tails of this vague idea, because I always believed the standard explanation for the structural defects and the resulting hopeless incompetence of a myopic eye.

The biggest mistake of my entire life.

Today's situation: I drive in -5,5 glasses and, away from home, have them handy at all times but seldom put them on. I write this wearing -2,5 glasses, sitting 1 1/2 feet away from the screen and using the zoom feature (115%) so I don't have to move closer. I have 20/60 or better unaided vision about 30% of the time indoors, about 60% of the time outdoors. Everything is slowly, gradually improving, I haven't experienced a setback so far. My biggest current problem is floaters: not new floaters (I recognize their shapes from ten years ago) but old floaters with a new visibility. They puzzle me a great deal because right now, they look like they are a major overlooked (no pun) component of myopia rather than a mere symptom. They interfere with my focusing, are probably responsible for my monocular polyopia (they "drag" additional images off the real one when they move across my center of vision), and move in TOTALLY DIFFERENT PATTERNS depending on whether I'm having a clear flash or not. I'm in the process of gathering information on the bastards and will be grateful for all contributions.

Elena

Subject: Corneal accommodation revisited
Status: RO
X-Status:

The modern theory that the lens is responsible for accommodation, and not the cornea, is usually credited to Thomas Young, who, at the age of 28, delivered a lecture in 1801, and published among the Transactions of the Philosophical Society of London. This article, according to every source I have come across, definitively proved that 1) the cornea does not change during accommodation to near and far distances, and furthermore 2) the crystalline lens, located behind the pupil, is responsible. It appears, however, that most people have not read this article. For if they did, they would be led to the article that Young was trying to refute, and they would conclude that Young's disproof was incomplete, especially since an extensive rebuttal was reprinted the following year, to which there was no response from Young in the Transactions.

It seems likely that it was Young's reputation as the originator of the modern physical concept of energy, his research on color vision, his study of astigmatism and other important areas in optics, not to mention his help in deciphering the Rosetta stone, that convinced people that Young had the right idea -- not a careful comparison of the relevant studies.

As a side-note, I add that corneal accommodation has recently been discovered to occur in chicks..

I reprint from the much-neglected article:

* * *

Final paragraphs of Croonian Lecture of 1795, by Howe (printed in the Philosophical Transactions of the Royal Society of London)

August the 28th, the former experiments were repeated by Sir Henry Englefield, Mr. Ramsden, and myself, on the eye of a young lad, and the result was similar to the others, the motion of the cornea was uncommonly distinct. Sir Henry now became the subject of the experiment, and changed the adjustment of his eye from one distance to another in a very irregular manner, without giving the smallest information, with a view to embarrass Mr. Ramsden who was the observer, but without effect, for Mr. Ramsden was able to tell every change in distance he had made, without a single mistake; this exceeded our expectation, and appeared to us so satisfactory that we required no further proofs of the truth of our former observations. Before we concluded our experiments, every mode that could be devised was put in practice to see how far there might be any deception; the eye was moved on its axis, and in different directions, but these motions did not give at all similar appearances to those seen in the adjusting of the eye to different distances.

>From the different experiments which I have had the honour to lay before the R. S., I shall consider the following facts to have been ascertained. 1st, That the eye has a power of adjusting itself to different distances when deprived of the crystalline lens; and therefore the fibrous and laminated structure of that lens is not intended to alter its form, but to prevent reflections in the passage of the rays through the surfaces of media of different densities, and to correct spherical aberration. 2d, That the cornea is made up of laminae; that it is elastic, and when stretched, is capable of being elongated 1/11 part of its diameter,

contracting to its former length immediately on being left to itself. 3d, that the tendons of the 4 straight muscles of the eye are continued on to the edge of the cornea, and terminate, or are inserted, in its external lamina: their action will therefore extend to the edge of the cornea. 4th, That in changing the focus of the eye from seeing with parallel rays to a near distance, there is a visible alteration produced in the figure of the cornea, rendering it more convex; and when the eye is again adapted to parallel rays, the alteration by which the cornea is brought back to its former state is equally visible.

Having supported these facts by the evidence of anatomical structure, and absolute demonstration, I shall consider them to be established; and make some observations on the muscular and elastic power by which so very curious an effect as the adjustment of the eye is produced. The 4 straight muscles of the eye are attached to the bottom of the bony orbit near the foramen opticum; they become broader as they pass forward, and when arrived at the anterior part of the eye-ball, are insensibly changed for tendons; these adhere to the sclerotic coat, and terminate in the external lamina of the cornea, which appears to be a continuation of them. When we consider the situation of these muscles, it is evident that their action will produce 3 very different effects on the eye, according to circumstances. When they act separately, they will move the eye in different directions; when together, with only a small quantity of contraction, they will steady the eyeball; and when this is increased they will compress the lateral and posterior parts of the eye. This compression of the eye will force the aqueous humour forwards against the centre of the cornea, while the circumference is steadied by the muscles, so that the radius of curvature of the cornea will be rendered shorter, and its distance from the retina increased. That the eye-ball cannot be made to recede in the orbit by any of these actions, is sufficiently proved by its not having done so in any of the experiments. These muscles are uncommonly large, and come much more forward than appears necessary for the purposes generally assigned to them; but when applied to so important an office as that we have just stated, their size, and anterior insertion, are easily explained.

It may be imagined that I have allotted to these muscles a greater variety of uses than is compatible with the simplicity of the general laws of the animal economy: but to prove this not to be the case, I shall only bring the biceps flexor cubiti as an instance of a similar kind. That muscle is attached to the scapula by both its heads, one of which passes through the joint of the shoulder, they afterwards unite, and their common tendon is inserted into the radius; when the muscle contracts, the first effect will be to steady the joint of the shoulder; if the contraction be increased, it will rotate the radius, and if still more increased, bend the fore-arm.

There are many instances in animal bodies of elasticity being substituted for muscular action, but this in the eye is by much the most beautiful of those applications. In the vascular system the arteries are composed of muscular fibres, and an elastic substance; in the natural easy state of the circulation, the reaction in the larger vessels is principally the effect of elasticity; but when increased, it is the effect of muscular contraction. The claws of the lion are drawn up, and supported from the ground, by means of elastic ligaments; but they are brought down for use, which is an action not so often required, by muscles. In the adjustment of the eye it is the same; the state fitted for parallel rays is the effect of elasticity, but that for nearer distances, which is less frequently wanted, is the effect of muscular action. In these different instances, the intention is uniformly to avoid the expence of muscular action whenever the effect can be produced in any other way, as muscular

actions consume a considerable quantity of blood, which is the nourishment of the body. That the adjusting the eye to near distances is the effect of an action, or exertion, was very evident to every gentleman concerned in these experiments. In changing the focus of our eyes, we were much astonished, particularly Sir Henry Englefield, at the exertion required to adjust the eye to the near distances, and the facility with which it was adapted to distant ones; the first was a strain on the eye, the 2d appeared a relief to it. When the eye was intent on the near object, it required the attention to be constantly kept up, or the object became indistinct, and if we looked at it beyond a certain time, the eye was so much fatigued as to lose it at intervals. This corresponds with other muscular actions, for whenever muscles are kept long in one state they begin to vibrate involuntarily.

These circumstances explain what may be called a coup d'oeil, or the distinctness with which an object is seen when the eye is first fixed on it. This arises from the nice adjustment produced by the muscles when first thrown into action, which they cannot keep up, being unable to remain long in the same state; nor can they, after having been used for any time, return to this adjustment with the same exactness.

The change that takes place in the eye at an advanced period of life, by which it loses its adjustment to very near, and at very distant objects, does not arise from any defect in the muscles, as might at first be imagined, since that would not account for the eye being unable to see with parallel rays; nor is there any obvious reason why these muscles should lose their powers, while others, which are not apparently so strong, if we may judge by their effects, retain their full action long after the eye has undergone this change. This defect in the eye, I am led to believe, is brought on by the cornea losing its elasticity as we advance in life, neither contracting nor being elongated to its usual extent, but remaining in a middle state. That elastic substances in the body do undergo such a change, may be well illustrated in the vascular system. The aorta is composed almost entirely of elastic substance, and there is probably no part of the body, at an advanced age, which is so often found to have lost its natural action; it appears to undergo change from age alone, becoming inelastic, and then taking on diseases of different kinds, as being ossified, or becoming aneurismal; but in neither of these diseases is it found to be contracted, though often the reverse, and when disease has not supervened, the artery more commonly remains in the middle state.

The cornea, having similar properties must be liable to a similar change; but its action being less constant, and the power which to resist being weaker, the change will be probably more gradual and less in degree, but sufficient to account for the alteration we find in the focus of the eyes of old people. There are many other circumstances respecting vision, and many which occur in disease, that may be explained by a knowledge of these facts; but as this lecture is only intended to establish the facts themselves, in doing which I have already taken up too much of the time of the R. S., I shall at some future period consider their application to the phenomena of vision in health and disease.

Fig. 10, p. 5, shows portions of the four straight muscles of the eye, with their tendons insensibly lost in the external lamina of the cornea, stretched out and dried. The tendons become broader as they approach the cornea, and form a circle of which the cornea appears to be a continuation.

Alex (and anyone else interested):

As you well know, the occasional posts to sci.med.vision on flashes of clear vision are answered with condescending remarks by the professionals. They are probably unaware that there are a few reports in the literature on this phenomenon. On re-reading a paper on "The resting state of accommodation" (Meredith Morgan, Am. J. Optom. and Arch. Am. Acad. Optom, Monograph 214, July 1957), I came across the following:

"Le Grand, using skiametry, found five subjects who showed negative accommodation during "flashes of clear vision" while wearing too much convex lens power...Morgan and Olmstead, using skiametry to measure changes in the refractive state of the eye, reported that sudden sensory stimuli, such as an electric shock or a loud noise, may cause a sudden decrease in the refractive power of the eye, usually not more than 0.25 D."

I noticed the same effect from a hard fall when hiking in the mountains--a flash of clear vision. I wonder if anyone else has had a similar experience. The comment about "wearing too much convex lens power" suggests a way to provoke flashes. How about wearing strong convex lenses while exposed to a loud explosion and receiving a strong electric shock! :-) (Would that produce a .75 D. reduction in lens power?)

Rich
