

International Society for the Enhancement of Eyesight

The **International Society for the Enhancement of Eyesight**, (founded 16 Jan 1995) is a web site and a mailing list dedicated to promoting better natural eyesight for everyone!

Simple, safe, and easy techniques have been known for at least a century that you can employ to prevent, lessen, and possibly completely eliminate blurry vision. These techniques of the "Art of Seeing" have been simply ignored by mainstream optometry and ophthalmology. It's time to change all that! You have nothing to lose but your glasses!

Directory of Documents

Revised 4 Jun 2003

Bates Method in a Nutshell

Based on *Better Eyesight Without Glasses* by William H. Bates (New York: Henry Holt, 1981), Chapter 24, "Fundamental Principles of Treatment", pp. 193-200. Note, this is a paraphrase, not a direct quote.

The means to better vision is through relaxing the eyes. Rest makes vision better, strain or effort makes vision worse. There are several ways to rest the eyes.

1. **Close your eyes.** While doing this, think of something agreeable.
2. **Cover your eyes.** Called "palming". If you cover your eyes so as to exclude all light, the eyes will be able to achieve a greater degree of relaxation. Cover both eyes with the palms of your hands, your fingers crossed on your forehead. Note: in order to be successful, you must be able to relax while palming. Some people cannot do this, and palming becomes counterproductive. The blacker the field you see, the more relaxed you are. But if you "try" to see black, this may cause more strain. Don't try to see black: it is better to imagine a concrete, familiar object or scene.
3. **Observe the swing of things.** As you move your gaze from one point to another, things seen should move in the opposite direction. For example, if you look at the upper left corner of the letter "H" and then shift your gaze to the lower left corner, the "H" should appear to move, or "swing" up. If it doesn't, this is a sign of strain. There are a variety of exercises to practice the swing. You can gently swing your whole body to the left and to the right, and watch a distant tree swing to the right and to the left, you can move just your head, or just your eyes. The better the vision, the shorter the swing can be made to be.
4. **Use your imagination.** By seeing things with your mind's eye, and remember them in precise detail, you increase your ability to see actual objects better. The perfect memory of any sensation can be produced only when one is free of strain. It also helps, when practicing with a test card, to imagine that the part of a letter that one is looking at is blacker than the rest of the letter, or to imagine a small letter within a small black spot of a letter. In this way you direct your mind to appreciating finer and finer detail.
5. **Catch those flashes.** When your eyes finally achieve a state of relaxation through swinging or palming, you will see a "clear flash"; paradoxically, the sight of everything in focus is such a surprise that it causes strain, and the blur returns. So before the clear picture blurs out, close your eyes and remember the image in its full sharpness and clarity.

6. **Keep your vision centered.** When you regard an object, only one small part should be seen best. This is because only the center of the retina -- the fovea -- has the best vision for detail. Farther away from the fovea, the retinal receptors get progressively less able to pick up fine detail. Therefore, trying to catch all the detail with all of your retina at once causes strain because it cannot be done! Instead of staring at the entirety of an image, restrict your attention to the smallest area that you can.
7. **Enjoy the sun.** Get out into the open and enjoy every sunny day. It is especially relaxing and stimulating to the eyes if you close your eyes and let the sun shine onto your lids as you sway back and forth.
8. **Practice with a test card.** Keep an [eye chart](#) on the wall. To practice, stand from 10 to 20 feet away, and read the smallest line that you can without straining. Then look at one of the letters on that line and close your eyes. Remember that letter -- go over every detail in your mind; shift from part to part, from curve to corner and so on. When you open your eyes, you will see not only that letter better, but also the one below it. If you find yourself staring at the letters, which results in the line becoming blurred as soon as it comes into focus, it is best to close the eyes before this can happen. When you open them, shift to another letter on the same line. If you close your eyes for each letter, you will become able to read the whole line. Practice every day for five minutes or more and keep a record of your progress.

Eye Charts

If you want to improve your vision with natural vision improvement techniques, such as the [Bates Method](#), you need an *eye chart*. With an eye chart, you can perform various eye exercises, and, of course, an eye chart provides an objective way for you to see your progress as you improve your visual fitness. As you experiment with various vision improvement techniques, the eye chart can help you decide which exercises work and which ones *don't* work for you.

Check out the [eyechart download](#) section for free eye charts, ready to print out (or use on screen) and use in measuring and training various aspects of vision; or, follow the instructions on how to [make your own eye chart!](#)

Using a [Snellen eye chart](#)

The chart is usually read while standing at a distance of 20 feet. Acuity is represented as a fraction, with the distance at which you are standing being the numerator (top part of fraction), and the normal maximum legible viewing distance ("Distance" on the chart above) as the denominator (bottom of fraction). So if, at 20 feet, you can read the letters on the row marked "40", this means you have visual acuity of 20/40 or better: 1/2 normal. From 10 feet, if the smallest letters you could read were on the "40" line, this would give you an acuity of 10/40: 1/4 normal. If you are nearsighted, your vision will become more normal the closer you stand to the chart.

How do you use *your* eye chart? Tell us about it on the [I SEE mailing list!](#)

Free eye charts to download!

- **Interactive Eye Chart:** Alejandro Saksida's Flash-based **Ultimate Random Snellen Chart generator, version 2.5** now with new and improved picture options (updated December 11, 2003):
 - Read [Instructions](#).
 - Generate a [Random Snellen Chart](#) on the web.
 - Download a [ZIP Archive](#) of the generator for off-line use.
- **Vision Training Charts** from Ray Gottlieb, O.D., Ph.D., with instructions
 - Presbyopia Reduction Chart ([PDF](#)) -- helps you read fine print by training convergence

- String Of Pearls ([PDF](#)) -- for improving 3D perception
- Alex Eulenberg's **1-page Snellen Chart (20/20)**
 - in [GIF](#) format (browser-viewable, also printable at 72 dpi)
 - in Macintosh [PICT](#) format (hi-resolution, downloadable & printable)
 - in [Encapsulated PostScript \(.eps\)](#) format (compatible with, among other programs, WordPerfect for Windows.)
 - in [PDF](#) format.
- Joel Schneider's **3-page Snellen Chart plus near vision testing card**
 - in [PDF](#)
 - PostScript [source code](#)
- Vic Cinc's Letter **rows & grid of random tumbling E's**
 - in [PDF](#) format
 - in [PostScript](#) format
- Vic Cinc's [Astigmatic mirror](#)

Make your own eye chart!

For those enterprising souls out there who would like to laserprint or draw by hand their own eye chart, or if you would like to verify that your printout is of the correct proportions, here are the specs:

Distance (feet)	70	60	50	40	30	20	15	10	7	4
letter ht (mm)	31	27	22	18	13	9	7	4	3	2
letter ht (pt)	88	76	63	50	38	25	19	13	9	5
font size (pt)	152	130	108	87	65	43	33	21	15	9

Interpreting the table

"Distance" in the above table refers to the furthest distance from the chart at which a normal eye is able to read the letter. On a Snellen eye chart, rows letters of a given size have the corresponding distance number next to them. Thus row of 18mm letters is marked "40". The font must be **Courier** (or **Courier Bold**) in order for the "font size" in points to correspond to the indicated letter height. Courier Bold is the PostScript font that most closely approximates the official Snellen letters.

Mailing List

The **I SEE** discussion group mailing list has a long history of good debate and conversations on all topics related to natural vision improvement. The group, currently hosted by [Yahoo! Groups](#), gets an average of 50-100 messages per week. Members can choose to be sent daily summaries or digests, or to keep up with the list on the web at the [I-SEE Yahoo! Group home page](#).

How to subscribe to the **I SEE** mailing list

To subscribe, send email (subject line and content does not matter) to i-see-subscribe@yahoogroups.com

How to regulate the frequency of mailings from the **I SEE** mailing list

To make changes to your account, you need a Yahoo! ID so you can log in and make the changes. You get your ID through the [Yahoo! Groups ID assignment wizard](#). Once you have your ID, you can switch to a daily digest mode, daily summary mode, or read-only-on-the-web mode. You can do this from the [I-SEE Yahoo! Group home page](#).

How to unsubscribe from the **I SEE** mailing list

Please do not send mail directly to the list if you want to unsubscribe. To unsubscribe, send email (subject line and content does not matter) to i-see-unsubscribe@yahoogroups.com

Problems?

If you have any trouble with the above procedures, visit our [Yahoo! Group page](#) for more information.

Mailing List Archives

We have archives of the mailing list, organized by topic (for 1995) and by month (for 1996 to January

1999).

Recent archives

Posts made since October 14, 1999 are available to members at the [Yahoo! Groups home page](#) (Yahoo! ID needed).

there was a story in a Sydney paper that a team of researchers had found
the cause of cataracts and expect to have a solution within a couple of years.
which will be based on either nutrition or a new drug. the story didnt go into
too much detail. so you might want to avoid the surgery until this becomes
more widely available.

Vic

What can folks do in the meantime? Do you know of any thing
that will be good for the eyes and at least help cataracts from
getting worse?

In other words, what should those of us who either have
cataracts or who are terrified of getting cataracts do to keep
our eyes healthy and prevent cataracts or like the lady who
posted at least keep them from getting worse?

And does anyone know WHAT nutrition is good for cataracts?

Thankyou so much for any help you can give.

Kellie

SCIENTISTS LIFT A VEIL ON CAUSE OF CATARACT BLINDNESS
Gavin Gilchrist (technology writer)

A team of Australian scientists believes it has solved one of the great mysteries of modern medicine: the reason for cataracts, the most common cause of blindness.

After 8 years of research, the team believes it has discovered a major cause of cataracts, a major defect in the eye lens.

In a remarkable finding - which was opposite to the expected result - the scientists found that people with cataracts broke down a common dietary

component, tryptophan, more quickly than those with normal sight.

As a result, people with cataracts had much higher level of key tryptophan by-products circulating in thier blood; it was known that those by-products caused lens damage.

The findings by the Australia Cataract Research Foundation at the University of Wollongong offers hope that early damage may be arrested or even reversed by lowering the levels of those by-products, either through a change in diet or by new drugs.

As well, it may be feasible to develop a test to establish those people at high risk of cataracts by measuring the rate at which they broke down tryptophan.

"Given that we really know nothing about what causes cataracts. I guess this is really the first clue about what might be causing this major cuase of blindness" said director of foundation, Professor Roger truscott.

"It changes the way we think about cataracts"

The finding, which is about to be published in the international journal Clinical Science, is the result of 8 years' research by Professor Truscott and Dr Anthony Elderfield.

Overseas research had suggested tryptophan might be involved in cataracts, so the Wollongong team decided to test the theory. First Dr Elderfield developed a unique test for the by-products, which are created when the body breaks down tryptophan, an amino acid absorbed from food.

Working with cataract patients from Sydney Eye hospital, the team found that those with cataracts borke down the tryptophan about twice as quickly as another group with healthy eyes.

While it is possible that the link between tryptophan and cataracts is coincidental, other evidence suggests that a coincidental link is highly unlikely.

Three of the seven know by-products reate powerfully with proteins similar to those that create the human lens.

Scientists can take any of the three and, in a test tube, cause the same change to lens protein that is seen in cataracts.

I cant find my food composition book, but these are avallable in most bookshops. the message seems to be stay away from tryptophan rich foods.

maybe somebody can post a list of these...

Thanks for the many comments. I haven't been ingesting aspartame but doubtless have been ingesting tryptophan. Problem is, since it's an essential amino acid found in turkey and soy products as well as meat, poultry, fish and eggs, where to begin? I'm a vegetarian but do consume fish and soy products. I suppose I could abandon them for a while and see what happens but would really appreciate more solid research info before such experimentation. Thanks Vic, for the article on the Australia Cataract Research Foundation. Any idea how to get in contact with them?

The current (January) issue of Universal Light Technology News has an article on using light therapy and nutritional support for cataracts. It's a bit long to type, but if you send me a fax number I can fax it to you, or you can call Universal Light Technology at 1-800-81-LIGHT and ask them for a copy. ULT is headed by Dr. Jacob Liberman, who has written several books on light therapy and vision improvement.

 - *Date:* Fri, 5 Jan 96 06:31 PST
-

Hello Mary Ann:

I appreciated your questions very much. I am thankful that others have answered your questions from the nutritional point of view, and I consider the discussion generated very important. On the other hand, my patients generally report to me that the physical approach to cataracts is only part of the continuum of focus that is needed to get to the root cause of this condition or any eye disease problem for that matter. Your request for a guess as to why the condition is present at a such an early age is one of my favourite and interesting questions I hear from my patients. Rather than attempt to diagnose your situation, I would recommend you read my book *The Power Behind Your Eyes*, and glean from the many non-eye exercise self-help processes whether you find your own answer. If on the other hand, you would like some guidance, I can offer this form of consultation. My approach is three-prong. I have my clients listen to self-healing audio tapes, in your case the one called cataract, change their eating style, you have already done this part, ingest a balanced anti oxident formulae with other ingredients, which have been discussed in this group, and use coloured light brought into and through the eye. Our portable units are under \$100 making them quite affordable. Any more questions, please let me know.

Robert-Michael Kaplan
B.C. Canada.

>I am 45, pretty nearsighted, wear contacts, and have been diagnosed with
>cataracts. One eye bothers me a lot with multiple images, light glare,
>blurry/cloudy vision. I have tried: some Bates/Meier Schneider type exercises,
>nutrition, good UV protection. I am not getting worse but not really getting

As part of our vision fitness programs, we provide our clients with pinholes and an instructional paper on specific exercises you can use while wearing the pinholes.

You can e-mail us or write

Protective screen filters

- *Subject:* Protective screen filters
 - *From:* Alex Eulenberg <aeulenbe@ezinfo.ucs.indiana.edu>
 - *Date:* Fri, 5 Jan 1996 13:47:07 -0500
-

On sci.med.vision. in article <4ci3g4\$qc4@news.vanderbilt.edu> Stefan Stefanov writes:

>Protective filters that are attached in front of computer screens are
>widely used in Europe. I am surprised to find that they are not popular
>in the US. In Europe I used what was known as an "optical filter" over my
>NEC screen. Now I don't use such a filter in the US (an HP screen), and
>my eyes get tired much more quickly.

Just a few days ago, I got a filter from OCLI called "Glare Guard" that supposedly blocks radiation in addition to eliminating glare. It does make viewing less "tiring" -- because of the glare reduction or because of the electromagnetic field radiation, I don't know. It cost \$30 at a discount office supply store. It has a plug for grounding. It's "approved by the American Optometric Association", for what that's worth.

>Does anybody have an idea how these filters work and if they
>are incorporated in the newest screens built?

I am told the radiation is blocked by a thin lead coating within the glass. The material that came with the product did not say how it blocked radiation, but it is supposed to block "95% of EMF radiation".

Some computers at Indiana University computer clusters are marked "low radiation." I did seem to notice a difference with those monitors.

--Alex

Can anyone please tell me how to make Windows colors easier to distinguish for someone with eye problems? Like with DOS you can set it for white on blue or white on black and it is real clear. Is there any way to make Windows print bolder and easier to read onscreen? I understand how to fix the printed print but I'm talking about looking at it onscreen. With so many folks with vision problems there must be SOME way to make it more clear but we sure can't figure it out.

Thankyou so much for anyone who can help.

Kellie

Windows 95 has a High Contrast option in the Accessibility Options applet in the Control Panel. This makes fonts and boxes much easier to read for people with vision problems.

Acckkk!!!! Do not upgrage to doze 95, please :).

If you have Windoze 3.1 (and 3.0, if I am not mistaken), you can change the color scheme.

Go to the MAIN window, double click on CONTROL PANEL, double click on COLOR and experiment with the choices. Also, you can change the icon size, grid thickness, etc, on the CONTROL PANEL.

I hope this will do what your want it to do.

Dr. Kaplan,

I noticed that you mentioned that you have a \$100 colored-light device. Is this device similar to Dr. Jacob Liberman's??

I have read Dr. Liberman's book, "Take Off Your Glasses and See" and was quite intrigued by his approach toward vision improvement. How would you compare your approach - similar or completely different??

Do you have any information or guidance with regard to treating myopia using colored light therapy??

I would appreciate any information you can give me.

Regards,

Bob Langridge

>Dr. Kaplan,

>I noticed that you mentioned that you have a \$100 colored-light device. Is
>this device similar to Dr. Jacob Liberman's??

I have taken a stroboscopic xenon variable flashing light source and modified the opening aperture. This device makes use of gelatin filters of the same frequency and combinations as used in Syntonic Optometry. I wanted to come up with a simple device that could be used at home by anyone interested in colour light balancing. The available instruments are more sophisticated and expensive. My clients have reported excellent results as documented in the book *The Power Behind Your Eyes*.

>
>I have read Dr. Liberman's book, "Take Off Your Glasses and See" and was
>quite intrigued by his approach toward vision improvement. How would you
>compare your approach - similar or completely different??

Jacob and I are very dear friends and have collaborated on many occasions and are currently working on a joint project. We have tended to focus on vision improvement from two distinctly different viewpoints. My focus has been on modified lens prescriptions, and using the iris interpretation to help explain some of the causes of vision problems. Other than this we both have similar vision therapy, psychoemotional and optometric experiences. My suggestion is to read my books, and then draw your own conclusions.

Hi Elena,

I have been myopic since I got the measles as a small kid and have been wearing hard contacts since the age of 18 (34 years ago). I was born in the US and came to Israel at the age of 24. I don't recall just how near-sighted I am but I am extremely so (so is my father).

I work in front of a computer most of the day.

I began to try Bates, based on some articles that I read via i_see on the Internet last week. I took out my contacts for a week but had to put them back in while driving. I felt my vision was improving a trifle but had to bend close to see things, which was not very convenient or productive at work. I put my contacts back in 2 days ago and my eyes have felt heavy since then. I do have a pair of glasses lying around the house and now, after reading your letter, I think I will try them, when necessary at work, instead of contacts. I hope it works out - I was foolish enough to think that the procedure was to go from contacts to nothing at all!

Hello listees,

I joined this list about a week ago and have been brousing hoping for some discussion regarding the bates method.

I'm quite myopic I've been wearing glassses for about 23 years now. I finally decided to take the plunge and seriously try the bates method. I've pretty much gone cold turkey and thrown off my glasses. For about two weeks now I've been stumbling around New York City and Brooklyn. I'm slowly getting used to my vision and the blur.

I can now see a sharpness within that blur. Some times I can read the sign at the church across the street or the words on all the papers around me. Usually this clarity disapears when I blink but comes right back again. I'm quite determind and trying to stay very positive about this but I must admit the evenings can get quite frustrating when my vision is less clear than the day.

I have been palming, sunning, yawning, stretching, shifting, swinging, taking vitamins, herbs, etc....

Are there any others on this list who have successfully thrown off their glasses and improved their vision?

Have others tried this on their own with out any teachers?

Feeling a little isolated out here in the blur thanks for your patience,
Alexandra Hill

Betty,

Sorry I didn't get back to you sooner. I meant to write after Thanksgiving but things got a little busy for me. I keep meeting new aspartame victims, though, so I thought this might be a good time to drop you a note.

The woman about whom I have written to you is doing better all the time. Her MS symptoms are GONE! She still has a problem with light sensitivity in the eye with the damaged optic nerve but that is gradually improving with time. Even during the holidays, she has continued to lose weight since giving up aspartame. She had been severely over-weight for many years and nothing that she did to lose weight worked for her. It is unfortunate that the diet products that she thought would help her lose weight did nothing but make her more unhealthy and obese. I am afraid that many women fall into that same trap.

Over the holidays, I learned that a business associate of my mother recently lost her job. She has lost her ability to concentrate and her memory is failing. She has some other neurological problems and was recently diagnosed with MS and depression. She is over-weight and has been on a series of unsuccessful diets for most of her adult life. We spoke to her and she agreed to give up aspartame. She is a confirmed skeptic but, at this point, she is desperate enough to try anything. I can only hope that we got to her in time to help.

I also found out that an elderly, diabetic friend of my parents is having some health problems. He has always been able to manage his diabetes through diet and exercise. Recently, his blood sugar has gotten out of control and the doctors have no idea why. I am sure it is related to his aspartame consumption and he has agreed to change his diet to see if that will help him.

I hope to have some good news to pass on soon about both these people

soon. It is amazing how wide spread these types of problems seem to be now that I know what to look for. Thanks so much for all of your helpful information and support.

RE: Phototherapy

Hi,

I noticed a discussion on Phototherapy about two days ago. During the thread Dr. Kaplan briefly detailed a color-light device which sounded interesting.

The reason for my interest is basically related to my daughter's (Melissa) amblyopia condition. Presently she has under gone traditional patching of the good eye, but unfortunately, after initial improvement her visual acuity, it appears that the improvement has stabilized. I am "NOT" trying to second guess her pediatric ophthalmologist (MD) but since Melissa's improvement has stopped I am seeking advice on what other "real" options exist. The following is Melissa's vision history:

The problem was noted in May of 95 she was 5.5 years old at point in time. No Strabismus was noted but she was amblyopic in here right eye. Optically corrected her amblyopic eye had a visual acuity of about 20/400. After about 4 months (around Sept. 95) of full time patching of her good eye her visual acuity was about 20/200 in her amblyopic eye, now as of Dec 29 no change has occurred - she is still at 20/200 acuity - optically corrected. A MRI has been done and no organic problems were noted. A specialist - a neuro-ophthalmologist at a Cleveland hospital was seen for a second option - this specialist said to basically quite patching because Melissa's amblyopic eye was not going to improve - no test beyond the normal eye exam was done. At present we are still full time patching under the direction of her original pediatric ophthalmologist.

At end of December 95 I took Melissa to a behavioral optometrist (BO) - until going online I wasn't even made aware that BOs existed! The BO detailed tersely Phototherapy (PT) as well as visual training (VT). The BO detailed Melissa would need Phototherapy about 2 to 4 times a week at a cost

\$20 per 20min session, and the VT would be about 2 times a week at about \$50 per session.

What I am seeking is the following:

Are the rates noted for VT and BO typical and fair?

How specific does the color have to be for the PT, example - 400nm +/- ?

What colors are used, or is it just guess work?

Can VT and BO be done at home?

What is the typical results for amblyopia problems treated via VT and BO.

How long for results - weeks, months, years?

I have an idea about making a very inexpensive home PT device, well less than \$100, but I need to know a few more details about the color wave number(s) and the photometric intensities typically used. I have an electrical engineering background as such this device would be interesting to build. Dr. Kaplan if would like to discuss this idea I would be pleased to talk to you about it.

Any feedback on any of the above will be appreciated.

In a message dated 96-01-11 11:17:01 EST, you write:

>Are there any others on this list who have successfully thrown off their
>glasses and improved their vision?
>Have others tried this on their own with out any teachers?

Hi,

I'm going through sort of the same thing. Except that I need my glasses, but am DETERMINED to eventually not need them.

I went and got a prescription for less than my 'charted' requirement.

ie - I was measured at -5.00, and my current glasses are -3.50. I wear them all the time. I figure that if I can't see anything (ie without my glasses) it actually won't do as much good, because my eyes might give up on trying to see clearly.

So far, it's really working, I can see much more clearly now than when I put the -3.50 on for the first time 6 weeks ago. I plan to go in again in another 2 months and get a -2.50 - see what happens...

Anyway, the -3.50 work fine for computer usage, everyday stuff, actually, everything except driving at night (that's still a bit of a problem). I haven't had the stronger ones on at all for 4 weeks now.

My doctor has never worked with this type of plan before, but is very open and helpful. He's interested in the ideas that I'm getting from this group!

Good luck!

Alice

I didn't save the message from the person that asked about buying bilberry seeds. However, I am told that there is an on-line catalogue at <http://www.datasync.com./sbe>.

I haven't had a chance to check it out yet, so I am not sure if they have bilberry seeds but the spammer that posted this address in one of the newsgroups said that they have a "collection of exotic, rare and unusual plant seeds".

Hope that is helpful to you.

Amanda

Hi, Alexandra!

You're not alone... I also have been working on my own at getting used to
life
without glasses. Unfortunately, I had a bit of a relapse over the
holidays,
but am getting back to it! I've been doing exercises about twice a day and
have been going without my glasses as much as I can. I've yet to brave
walking
about the streets without them in my pocket, at least, since I usually have
my
3 y.o. daughter in tow. But just the other day I saw a one way sign half a
block away -- it really made my week!
I've worn glasses for 22 years, and it's taken me about six months or so to
get
this far. Hold on to the clear flashes! They start coming more often and
staying longer. Just before Christmas, I had a clear flash while I was
looking
at my eye chart. I could actually see the 20/20 line and it lasted for
about a
minute -- long enough for me to look up and realize I could also read some

small words on a poster that had been a black blur a moment before. It gets better -- just keep working at it!

Also, does anyone have that Canadian address for pinhole glasses that someone posted a while ago? I accidentally deleted it.... Or does anyone have any other places where I could find a pair? I'd like to stop having to wear my glasses while I'm at the computer and doing other close work. Thanks!

-

This is a sequel to "thumb-watching".

Materials necessary:

- 1 pair eyes
- 1 pair thumbs

Preparation:

1. Open both eyes; remove all lenses
2. Hold your right thumb between your eyes as close as you can without it becoming blurry or going double.
3. Extend your left arm, thumb up. Keep focusing on your right thumb. You should see in the blurry distance not one, but two left thumbs.

Now for the action!

4. Look at your left thumb-images. Are they level? Is one thumb-image higher than the other? (Remember, keep your focus on the right thumb.) Watch what happens when you tilt your head. When the thumbs are level, is your head upright? It should be.
5. Change focus from your right thumb to your left thumb. Watch your left thumbs snap together to become one, as your right thumb splits into two. Do your left thumb-images snap together, or does only one thumb move? Does one thumb fade? If such things occur, this means that one eye is dominating. Make both eyes dominate. Align your thumbs so that the single-image thumb will always be right smack in the middle of your two double-image thumb images. Switch your gaze back and forth from thumb and always be aware of the splitting and merging of thumb-images.

6. Keep your gaze fixed on your right (closer) thumb. See the ridges (and dirt, if any) on your thumbnail. Keep it in focus. At the same time, wave your left thumb around. Now, keep your left hand still, and move your right hand out towards your left, and back again, always maintaining focus on your right thumb. Always notice how the left thumb images come closer and farther apart, and how they become more and less focussed. Now fix your gaze on your left (farther) thumb, and do the same motions.

Variations / Substitutions:

1. Use a pen instead of your right thumb. Use any distant object as your left thumb (will not work for first half of #6).
2. Put a pen between your eyes and a text. You should have two see-through pens. Look "under" each pen and read the text. Is one pen more solid than the other? Do you see only one pen? If so, that means one eye is being "turned off" as you read.

What to expect:

Heightened 3D perception and new sense of balance. Improved clarity. Easing of tension in the eyes.

Note: as with all exercises, if you do this too "hard" you may get eyestrain. If you feel a pain or stinging in your eyes stop, relax (palm), and try again later.

Also important: Do not try to see the double-image thumbs as clear! Always be aware of them, but see them fuzzy, as they should be, since you're focusing on the other thumb!

>Alexandra Hill

Hi Alexandra,

I have also attempted Bates style vision improvement without a teacher. I stopped wearing my glasses about two months ago and have never worn them since. My vision has slowly improved and I have had genuine flashes of very clear eyesight. I am currently living in Holland where the some of the TV shows are in English and subtitled in Dutch. I find that I can move further and further away from the television and see the subtitles with the same clarity.

I have tried various exercises such as palming, swinging, tracing the outline of objects with my eyes but in general I don't do these exercises as much as I should. I tend to work on the emotional aspects of poor eyesight, the things that stress me out. I think my poor eyesight is a combination of poor visual habits and these emotional aspects but the biggest gain I think I can get is not so much perfect vision but living in a more confident and open manner. Most of all being more aware of myself and what is going on around me.

So don't worry you are not alone and the more you believe you can improve your vision the better it gets with time.

Cheers

Sean Woodward

Actually we have a similar prescription mine is -5.00 right and -5.25 left.
My eyes have not given up on trying to see clearly. I suppose I will
eventually get some transition glasses so I can start leading a more normal
life. I decided to go cold turkey because I have some time on my hands at
the moment. I'm unemployed and no pressing responsibilities. I'm a painter
and I'm looking forward to seeing the world with a new clarity.

Well, not really...

Over 2 years ago, my prescription was:

R: -6.50 -1.75 10
L: -6.00 -2.25 170

Right now, I'm wearing an old -5.25/-5.50 pair, and they're starting to annoy me. (I did attempt to get new glasses a year and a half ago, but was shown straight to the door when I told the optometrist I was still breastfeeding. Nobody had warned me about the temporary increase in myopia that new moms get!)

That one great clear flash was on a "good" morning right after doing my exercises -- I haven't been able to duplicate it... yet. I was so stunned when I saw the 20/20 line, I guess my eyes stayed relaxed, but when I started to realize what was happening, I lost it. During the busy holidays, I kept forgetting to take my glasses off, so my eyes have backtracked a bit. New Year's resolution: tell family & friends that if they see me with glasses to yell, "Take 'em off!"

On good days -- especially mornings -- I can see the larger print on my computer screen clearly, but I still can't make out the small stuff. I'm a

weaver (still a hobby, someday maybe a business...), and if I weave without my glasses, I find I tend to lean too far over the loom, which is hard on my back. This is where I hope pinholes can really help.

I'm overdue for an eye exam, so when I've got new numbers, I'll let you know! (Unofficial measurement with ruler and paper with text was 4 diopeters this evening.)

Thanks for a great list! Wish someone had given me this kind of information way back when I was in 1st grade....

Well, in any case, I was correct about the astigmatism. Anything over 1 diopter is considered "major". Some doctors do not add cylinders if they find less than a cylinder-diopter of astigmatism.

Were you standing at 20 feet? If so, this is absolutely amazing.

> During the busy
> holidays, I kept forgetting to take my glasses off, so my eyes have
> backtracked a bit. New Year's resolution: tell family & friends that if
> they see me with glasses to yell, "Take 'em off!"

Something to think about: when you learn to see well without pure spherical (i.e. non-astigmatic) glasses, you are merely learning to ease up on your focusing, which is a natural function of the eye. But if you learn to see well with and without cylinders (astigmatic correction) this means you must be warping and unwarping your eye asymmetrically, which of

course, is not a natural function of the eye. According to the standard theory, this means "sectional accommodation" of the crystalline lens inside the eye. I am more tempted to believe it is the extraocular muscles pulling on the cornea in an uneven fashion, originally brought about by strain, but then later reinforced by lenses. In general, it is accepted that most astigmatic aberration is detectable in the cornea and not the lens. For evidence to support the idea that the cornea can change its shape -- its amount of astigmatism -- in response to the actions of the extraocular muscles, see the "Incredible Changing Cornea" bibliography on the I SEE page...

http://silver.ucs.indiana.edu/~aeulenbe/i_see.html

Read especially the link there to excerpts from a 1930 article by J.W. Parker, entitled "Changes in Corneal Astigmatism"

Anyway, the upshot is: when you get your next pair of reduced-strength glasses, ask your doctor if you can get them WITHOUT a cylinder component. This way, you will be able to train yourself away from astigmatism 100% of the time.

Hello Alexandra! You sound like you are doing great!

I am interested in your comment about having less clear vision in the evening. Many things (lighting, diet, exercise, state of mind, fatigue, etc...) influence my vision. I found the use of full-spectrum lighting in my home to be very helpful in reducing blur and creating a more comfortable visual environment. The bulbs that I use are "Chromalux".

As far as being isolated in the blur...I started VT about eight months ago. I also gave up glasses cold turkey and I know how tough that can be at first. You should be very proud of yourself for taking that step. (Time-out while we all pat ourselves on the back.) One thing that has helped me is talking to people about my vision improvement. At first I expected people to think that I was a total flake. That has not been the case though. Most people are very supportive and many of them want me to teach them the exercises that I do. Anyway, that may be something that can help you feel more confident navigating the world.

Good luck!

Amanda

I got some chromalux bulbs too, one is 150 watt and reading under that is great. My vision feels worse because of the dimmer light so things I could see during the dy I can no longer get into focus if I were to shine a bright light on everything I could probably see as well as during the day .

Some people are supportive, some curious, some almost hostile the hostile

ones are either afraid of it or feel competitive because they aren't about to do it they wish no one else to try. What has been your experience since taking off your glasses eight months ago? What was your prescription and how have you improved? How much do you work on it, How often?

Alexandra,

You have raised some interesting and complex questions. I will do my best to answer them. When you start seeing real and permanent improvements in your vision, you will understand why this is so complicated.

Before I get into any of that though, I want to thank you for your astute analysis of how different people react to the idea of vision improvement. There are several people that I care about that have a very negative reaction toward the idea of vision improvement. This is something that has bothered me more than it should. My vision is a major part of my life now and I would like people to accept that. I have been trying to figure out why someone would feel so threatened by that. I think that you may have hit the nail on the head though. Thank you for sharing your insight.

Now, as for my vision, as I recall I started out with the following:

R: -2.75 -1.75x10

L: -2.50 -1.75x170

My latest glasses are -1.50/-1.25. I see clearly through them most of the time. I should probably get a weaker pair but I rarely wear them, so it hardly seems worth it. I can see well enough to function day to day without them. I know how to start a clear flash now so, if I really HAVE to see very clearly, I usually can. I try not to force that though. I believe that it will come when it is ready to. The astigmatism is gone most of the time. My lack of astigmatism was verified by my optometrist in September. Boy, was he ever weirded out! The astigmatism does still rear its ugly head from time to time. That is only when I am tired or under stress though.

A little history.... My introduction to VT came last summer when I took a four week course with a woman in my community who teaches Natural Vision Improvement (the Janet Goodrich kind). A lot of the material zoomed right over my head. I was just looking for some eyeball calisthenics that would solve all my problems. I have since learned that it doesn't work that way. There is an psychological aspect of my vision and that is something that I am concentrating on at present. I have taken some "advanced" classes with the same teacher recently. That has been helpful in keeping me focused on my vision and has also given me a support group.

As far as exercises.... Well, palming is an absolute must. I try to do 10 minutes at bedtime and anywhere from 10 to 30 minutes in the morning. That all depends on my frame of mind. If I am letting hundreds of little worries eat away at me, palming does not help much. In the morning, I stop palming as soon as I start feeling that I have to plan my day.

If I have trouble settling down for palming, I relax with something that I call "body breathing". I am not sure whether I invented this or read about it somewhere. Anyway, I lie on my back and take a big, slow breath through my nose with my eyes open. I imagine the air filling my whole body like a huge balloon. Then I close my eyes and exhale slowly through my mouth and feel myself completely deflating. Then I do the whole thing again, if I can. After a while, I start yawning like crazy. That is fine. I just fit in the body breathing between yawns or I give up and just yawn continuously. That is very relaxing for me.

During the day, I try to remember to rock my head. Big, slow ear-to-shoulder, nodding, and chin-to-shoulder motions are great for releasing the tension in my neck and shoulders that affects my vision. Sometimes that makes me yawn too. It depends on just how tense I am.

As far as more active vision exercises, I do all the basics (shifting, tracing, swinging, etc.), as well as some that I invented, as often as I think of them. I have a desk calendar that has a new computer-generated 3-D picture each day. I use +2 D lenses if I am doing a lot of close work. I have become very conscious of central fixation and not trying to see too much at once. I spend a lot of time outdoors and I just try to appreciate the things that I can see. Once I stopped fighting the blur, I found that I can actually see pretty clearly at times. I am also noticing lots of things that I have never seen before, even though they have always been there. In addition to the usual dietary stuff, I take a bilberry supplement that has helped with my night vision. (That took about a month.) Since I live in Vermont and we don't have much sun this time of year, I have a lamp with a 150 W full-spectrum light bulb for indoor sunning.

This is probably going to sound like a cop-out but I think it is

important for you to do the exercises that most appeal to you. Those are the ones that will help you the most because you will enjoy them. I think that you already know what exercises are right for you. It is just a matter of following your intuition. For example, when I was reading Dr Kaplan's first book (I think it is called Beyond 20/20), I came across an exercise called "swing ball". I was very much attracted to this exercise and had no idea why. I just had to drop what I was doing and go buy the props for this game. This activity turned out to be great for my astigmatism and also helped with over-all relaxation. This is still my favorite vision activity, not only because it improves my vision but also because I love doing it, even though my cat tries to use my face as a launch pad to GET THAT BALL. If I were you, I would just read the I_See FAQ and pick the things that sound like FUN to you and that you would enjoy bringing into your life. Remember, if you get bored with the ones that you are doing, you can always go back and find some new ones in the FAQ, dream up some of your own, or get suggestions from the people here.

It has been important for me to recognise that there is a significant emotional component to my vision. I believe that is something that needs to be dealt with for lasting vision improvement to occur. I approach this with the understanding that the reasons for my visual blur are buried in my sub-conscious. Before I go to sleep, I ask my sub-conscious to give me a hint (ie a dream) that will help me understand what my issues are. I have had great success with this. A year ago, I never remembered my dreams. Now I remember many dreams and they have helped me understand myself better than ever before. I have found that it is more important to acknowledge the issues than it is to devise a solution to them.

I am told that another approach is to think about what kinds of things were happening in your life when you got your first glasses. This is tough for me because I have worn glasses since age six. However, this has been helpful to me in dealing with issues in my family. I have found that there are situations in that area of my life that cause my vision to "switch off". It has been important for me to acknowledge these situations and their causes. I don't actually DO anything about them. I just accept that they exist and that I may not have any control over them. Then the worries that I have about them seem less daunting.

Hmmm...I have written lots and, believe it or not, this is just the tip of the iceberg. I could probably go on for days about this stuff. This is still seems like a good stopping point for right now. I hope this is helpful to you. Feel free to let me know if you have any questions.

Take care,
Amanda

-

Hi there,

I am new to this forum and absolutely delighted to have learned of it. I have been working with VT off, but mostly on for about four years. At the very beginning i had great progress. In about a month, i reduced my prescription from -7.5 both sides to -5.5. Unfortunately -- and i don't want to discourage anyone -- not much has changed since then, vision wise.

I came across the idea of VT while reading one of Jane Robert's Seth books in which he states that our reality is based upon our beliefs. Soon after reading what he had to say about glasses, i came across the Kaplan method which i followed and achieved my first reductions.

About 2 weeks into the Kaplan plan i had a flash of vision, not like the little ones where you can see the bottom line of the chart for a few seconds, (i have these too) but a really amazing, stereoscopic, breathtakingly colourful view of the world. At first, i was just stunned, but almost right away i felt crushed with sorrow, like i didn't deserve this. The vision lasted about 15 seconds. I wasn't doing anything particular when it happened, just walking the dog like i do everyday, thinking about nothing. I have had no repeat.

I keep getting back on the program, doing the exercises etc, but this experience has taken me away from the material side of VT towards a more emotional, psychological base. Is anyone else out there working on VT from this viewpoint?

Also, i have read Jane Goodrich's book, where she describes the imagination as being most important. I do have a vivid, verbal

imagination, but when i try to visualize anything inside my mind's eye, i see absolutely nothing. I have asked around and most people find this difficult to believe, but i see nothing inside my head. Is this a typical myope situation?. Should i concern myself and try to fix it? Does anyone have thoughts on this?

Thanks

Linda

Hello fellow I_See-ers.

A brief pragmatic question - where can I buy an eyechart?

Thanks for any info.

Stefan

Bates method

- *Subject:* Bates method
 - *From:* "George Tohme" <PolySoft@msn.com>
 - *Date:* Sun, 14 Jan 96 05:35:19 UT
-

Hello All,

I got the first batch of messages from this mailing list a couple of days ago and I quite enjoy reading about your experiences.

I'm looking for a bit of advice in relation to my eyes (obviously). I suddenly became myopic at the age of 11 or 12 (I just realized that I wasn't able to read some stuff on the blackboard) so the doctor said that I was myopic and that I had a bit of astigmatism. He gave me some glasses to wear but I could not stand the astigmatism built into them (I hope I'm using the correct terms). In other words everything was twisted!! If I looked down at my feet I could see the ground really high near my feet a lower away from them. (A perfectly square shape would appear to have the top side wider than the bottom one). To cut a long story short, the doctor agreed to prescribe some glasses for myopia and forget about the astigmatism.

The prescription did not change for about 10 years and I had perfect vision while wearing them. Then I decided to try soft contact lenses which I have been wearing for almost 8 years. The main reason I switched to contact was because I needed sunglasses and I did not like to wear dark glasses all the time.

All these years I could not believe (and I gave all the doctors I have seen some hard time about it) that the only answer for myopia was to wear glasses.

Anyway, few months ago I had an minor infection in one of my eyelids and I could not wear my lenses so I went to get a prescription for glasses. The optometrist convinced me that it's better to wear glasses with the astigmatism bit. When I got them the distortion was very bad. He then prescribed a pair with no astigmatism. Less distortion but extremely annoying and DIFFERENT: A perfectly square or rectangular shape (like a computer screen or a door frame) would appear to have the left and right sides CURVED just like this (). I'm not kidding.

I saw a number of doctors and they all said that my brain will adjust. Well my brain did not adjust. And then they said it is because I've been wearing contacts for a long time and that I've become a contacts junkie!.

Now I want to try to get rid of my contacts and glasses (which I still keep just in case) using whatever method that you people are trying but the problem goes like this:

1- I need to wear my glasses/contacts (-3.25, -3.25) to be able to drive the car and also work on the computer

2- I cannot use the glasses all the time or on and off because I cannot wear my sunglasses (even normal day light makes my eyes water like I've witnessed a terrible tragedy and been crying all day). BTW, my current glasses become darker when they're exposed to sunlight but they don't give me the kind of protection I need.

Any ideas on what I can do? Everybody is talking about throwing away their glasses but I cannot do that. Also a number of you have referred to the bates method but I cannot find any detailed info about it. Are there any exercises that I can do? can these exercises be done some time during the day and continue to wear the glasses after/before the exercises? How about wearing + glasses? Has anyone tried that?

many thanks

GeorgeFromDownUnder

Thank you for your comments Amanda. This Swing ball vision practise has probably brought more results for all vision conditions than any other vision game I teach. Not only is one teaching the mind to let go, but the exploration of space is particularly important. For those of you new to this vision game. You first lie down on your back underneath a brightly coloured ball that you swing in the primary directions. BTW This activity has been used in Behavioural Optometry for years. The ball would ideally be about 16" from your eyes. Feel your eyes following the ball and become aware of all the space surrounding the ball. This will reinforce the central fixation idea that Bates taught. For a deeper understanding, read the book Seeing Without Glasses, published by Beyond Words at 1-800 284-9673, and if you need some additional help, we provide swingballs as part of a vision fitness kit with eyecharts, patches etc, all the tools you need.

We even have audio tapes taking you through the vision games. It is like

Does anyone know about eye drops that are suppose to be great for cataracts? I read on internet that "Question & Answer Productions P.O. Box 30001 North Las Vegas Nevada, 89030, They sell drops that will clear up cataracts". Does anyone know more about these?

And I hear the natural vision faq mentions exercises and "succus Cineraria maritima". Can anyone please tell me what the exercises and "succus Cineraria maritima" are? Thankyou so much.

Hi George,

If you're in Australia you might want to look up Janet Goodrich, she's down under and gives workshops on vision improvement. She's also written a book, *_Natural Vision Improvement_*, wherein she incorporates Bates and others into a comprehensive vision improvement program. (If you're in the U.S. the book is available here too.)

I would also suggest finding an optometrist (behavioral or otherwise) who will support you in your efforts; otherwise you'll keep arguing with your optometrist about prescriptions, methods, etc. which eats up a lot of your energy and turns it into an uphill battle.

After a bunch of looking into berries, it turns out that there's a bit of "looseness" in what people call the berries in the *Vaccinium* species (blueberry, huckleberry, bilberry, whortleberry, cranberry); huckleberries are not bilberries, but have been called bilberries by some people.

Bilberries look pretty amazing from the articles I found; not only do they help night vision and myopia, but osteoarthritis, varicose veins and proneness to bruising, gastric disturbances (including colitis), blood clotting, etc. Much of this is clinically proven, too!

I found many sources for processed bilberry (capsules), and for bilberry nectar, but I'm still looking for a source for a starter plant or cutting (my wife, the botanist in the family, tells me that it would take years to get going if we started from seeds). I'll keep looking...

Dear Group

As a result of diabetes I've had hemorrhaging within the retina causing a complete loss of sight to my right eye. I've had laser treatment for the past six months while waiting for the blood to be reabsorbed but without success. My ophthalmologist is now scheduling a vitrectomy.

Can someone let me know what the procedure entails, risks, chances for success etc. Is there a continued improvement after surgery. Do they actually scoop out the eyeball & put it back? For how long is one disabled i.e. unable to work? Any and all information anyone can give me would be greatly appreciated.

Thank you kindly,

Charles

Dear Charles: If you are a diabetic you may be on aspartame marketed as NutraSweet, Equal, Spoonful and who knows what since the patent has expired. It has wood alcohol in it (methanol) which converts to formaldehyde in the retina of the eye, and then formic acid. Doctors mistake the vision problems caused by aspartame as diabetic retinopathy.

When Dr. Ralph Walton did an independent study not funded by the NutraSweet Co. (Monsanto) the study had to be stopped because of conjunctival bleeding from the eyes, and one patient got a retinal detachment. Others reported they were poisoned. He could understand why the NutraSweet Co. had refused to sell him the aspartame - they knew what would be found on independent study.

Many people are going blind in just one eye, and there is a letter from the late Dr. Morgan Raiford about that on the auto-responder under aspartame and the eye. He was a specialist in methanol toxicity and many of the patients who went blind on aspartame were brought to Atlanta to be diagnosed by this ophthalmologist. Now that he's gone we're having a hard time finding ophthalmologists who are specialists in methanol toxicity. Shannon Roth went blind when aspartame was in 100 products, Joyce Wilson when it was in several hundred. Now its in 5000. Dr. H. J. Roberts, the world expert on aspartame, and a diabetic specialist has warned all diabetics off this poison. His position paper on aspartame and diabetes is on the auto-responder, and there is an article where they tried to ban aspartame back in the 80's because people were going blind. Dr. Roberts says people on aspartame should be off of it for several months before having surgery because the problem may resolve on its own, if you're on this. He has written books on the subject and you can get his tapes on aspartame at 1 800 814-9800. He discusses how long you should wait for surgery if you're on aspartame.

You can get safe substitutes for sweeteners at any health food store but we also have a safe sweetener list on the auto-responder. There is also

a post on Stevia which is ideal for diabetics because it helps in the metabolism of sugar and is a food and not an additive. There is a resource list. I would also suggest you read Dr. Julian Whitaker's book REVERSING DIABETES. It's the best I've read on the subject.

In Dr. Roberts book and Dr. Russell Blaylock's book Excitotoxins: The Taste That Kills (Health Press - 1 800 -643-2665) it explains that aspartame actually triggers diabetes! I'll send you a copy of our warning flyer which will give you more information and the name of publications and a post I did on diabetes and aspartame.

If you're on aspartame, please take the "no aspartame test" and get back in touch with us later with your history. You may be surprised to find your medical problems have disappeared! You will see case histories on the auto-responder where people's vision has returned after removal of aspartame. I'll be glad to give you their phone numbers. They have given their permission. Many people who get well want to then help others. Be sure to read the Joyce Wilson story and you will see how serious it is.

To use the auto-responder, instructions beneath my signature, please put sendme help in the subject line and you will get a directory. Like this:

Subject: sendme help

When you get a directory simply put sendme in the subject again along with the file name of the file you want as typed on the lefthand side.

Regards,
Betty

To get more information on aspartame, email betty@pd.org the following:
Subject: sendme help (do not put anything in the message text)

Betty Martini	1. Take the 60-day No-Aspartame test
Mission Possible	and send us your case history.
PO Box 28098	2. Tell your doctor and your friends.
Atlanta GA 30358	3. Return Aspar-Poisoned foods to the store.
USA	(Nutrasweet(tm), Equal(tm), Spoonful(tm), etc)

We are dedicated to the proposition that we will not be satisfied until death and disability are no longer considered an acceptable cost of business.

Wow, does this ever sound familiar! George, I absolutely relate to what you are going through. I am also a myopic/astigmatic person, though I was more astigmatic and slightly less myopic than you seem to be. Before I gave up glasses and contacts last summer, I had been wearing contacts for more than 12 years. In that time, I became more and more sensitive to sun light.

The driving/computer use dilemma can be solved by purchasing a pair of glasses that correct your vision to 20/40...er, I believe that would be 6/12 in your part of the world...with no astigmatic correction. These glasses will give you enough clarity to see the things that you need to see and also give your vision an opportunity to improve.

The light sensitivity issue...my eyes used to react similarly to light. I had to wear sunglasses whenever I went outside. It could be sunny, cloudy, raining, snowing. It didn't matter. I would walk outside and I just felt like my eyes wanted to shrink into the back of my head. I increased my tolerance to light by sunning (exposing my eyes to direct suniight WITH MY EYES CLOSED). Within a short time, I had no adverse reaction to sunlight at all. During that time, I used homeopathic Euphrasia officianalis (a.k.a. "eyebright") to prevent the flood of tears

and the discomfort that accompanied them.

I hope that helps!

Good luck!

Amanda

Vic - Deus Ex Machina very kindly sent me the natural vision faq for which I can't thank him enough.

>> Succus Cineraria Maritima. Has been shown to increase the circulation between the tissues of the eye. Has also been shown to reduce of the opacity in cataracts.

>> an example program for cataracts ... Eye massage. Stretching the eye muscles. Relaxation and passive work

Can anyone please tell me where I would find Succus Cineraria Maritima and info about the eye massage?

There were lots of books listed in the faq (and I look forward to reading and making notes on the whole thing - it is FANTASTIC) but since it will take me a long time to track down all the books I'd really appreciate it if someone could give me info on where I might find info on the above two things.

Thank you so much for any help anyone can give me and THANK YOU everyone who participated in that phenomenal faq and especially to the super kind person who sent me a copy.

This group is great!

Kellie

>may have hit the nail on the head though. Thank you for sharing your
>insight.

Thanks for your response. Sorry it has taken me so long to respond. But
wihout any glasses typing at this computer can be very tiring.

It is true there are alot of things to deal with psychologically when
taking on vision therapy. Not only peoples reaction to it but also the
feeling of a change in ones personality which comes with a change in ones
vision. I am excited about getting out in the world and seeing it fresh
with a new perspective.

>A little history.... My introduction to VT came last summer when I took a
>four week course with a woman in my community who teaches Natural Vision
>Improvement (the Janet Goodrich kind).

There is an psychological aspect of my vision and that is
>something that I am concentrating on at present. I have taken some
>"advanced" classes with the same teacher recently. That has been helpful

in

>keeping me focused on my vision and has also given me a support group.

It must be very helpfull to be going thru this with other people I am greatfull to Alex for starting this list because so far it is becoming my support group. It is quite hard for others to really understand what you are going thru. I enjoyed Janet Goodrich's book it was very axcessible.

>As far as exercises.... Well, palming is an absolute must. I try to do >10 minutes at bedtime and anywhere from 10 to 30 minutes in the morning.

When you palm do you visulize movement or black?

>If I have trouble settling down for palming, I relax with something that >I call "body breathing". I am not sure whether I invented this or read >about it somewhere. Anyway, I lie on my back and take a big, slow breath >through my nose with my eyes open. I imagine the air filling my whole >body like a huge balloon. Then I close my eyes and exhale slowly through >my mouth and feel myself completely deflating. Then I do the whole thing >again, if I can. After a while, I start yawning like crazy. That is >fine. I just fit in the body breathing between yawns or I give up and >just yawn continuously. That is very relaxing for me.

It seems that creating you own exercises is a sign that you are tuning into your bodies needs and therefore more receptive to what is right for you . I am intrigued by how unique everyone experience is. Alot of this is feeling your own way which is so anti western medicine where you are taught to take a pill and deaden your bodies responses. I think some of the hostility you find by people to this vision therapy is often a fear of their own bodies.

>During the day, I try to remember to rock my head. Big, slow ear-to->shoulder, nodding, and chin-to-shoulder motions are great for releasing >the tension in my neck and shoulders that affects my vision. Sometimes >that makes me yawn too. It depends on just how tense I am.

I try and do some self massage and some accupressure points every day. One thing that got me into really trying this instead of just thinking about it was my experiences with Tai Chi and standing meditation. I found when I did standing meditation my left eye watered alot this is the weaker eye with a slight on /off astigmatism. After a few weeks I tried reading without my glasses and found it much easier. I used to favor my right eye. It was as if by doing standing meditation I was balancing out my eyes. I highly recommend it.

I spend a lot of time outdoors and I just try to
>appreciate the things that I can see. Once I stopped fighting the blur,
>I found that I can actually see pretty clearly at times. I am also
>noticing lots of things that I have never seen before, even though
>they have always been there.

I wish it wasn't so cold all I wan't to do is sit in the park or go to the
zoo and draw . I have no interest in going into my studio to paint it seems
to insular to enhancing of my myopic condition.

>This is probably going to sound like a cop-out but I think it is
>important for you to do the exercises that most appeal to you. Those
>are the ones that will help you the most because you will enjoy them. I
>think that you already know what exercises are right for you. It is just
>a matter of following your intuition.

I agree with you ,but I find the ones I avoid tend to be the ones that I
need the most . For instance the General Electric game is a struggle I am
close to really getting it.

For example, when I was reading Dr
>Kaplan's first book (I think it is called Beyond 20/20.), I came across
an
>exercise called "swing ball". I was very much attracted to this exercise
>and had no idea why. I just had to drop what I was doing and go buy the
>props for this game. This activity turned out to be great for my
>astigmatism and also helped with over-all relaxation. This is still
>my favorite vision activity, not only because it improves my vision but
>also because I love doing it,.

You've inspired me to try this one. Thanks :)

>It has been important for me to recognise that there is a significant
>emotional component to my vision. I believe that is something that needs
>to be dealt with for lasting vision improvement to occur. I approach
>this with the understanding that the reasons for my visual blur are
>buried in my sub-conscious. Before I go to sleep, I ask my sub-conscious
>to give me a hint (ie a dream) that will help me understand what my
>issues are. I have had great success with this.

Yes, this is important to be open to guidance.

>I am told that another approach is to think about what kinds of things were
>happening in your life when you got your first glasses. This is tough
>for me because I have worn glasses since age six. However, this has been
>helpful to me in dealing with issues in my family. I have found that
>there are situations in that area of my life that cause my vision to
>"switch off". It has been important for me to acknowledge these
>situations and their causes. I don't actually DO anything about them. I
>just accept that they exist and that I may not have any control over
>them. Then the worries that I have about them seem less daunting.

Some of this stuff about thinking about what was happening to you when you first got glasses kinda bugs me. Granted I daydreamed and drifted off staring into space in school. I got glasses when I was ten . Being nearsighted and going thru vision therapy makes my want to focus my sights on the future to be more extrovert ed and not to focus too much on the past . That is what is so weired about the exercises, for instance palming what an anti-social thing to do. And not wearing your glasses, well I feel more open but not being able to see peoples expressions makes it tough I find my self avoiding eye contact sometimes. It all makes me more determined to see this thru and keep going .

Best of luck to you I've rambled for way too long.
alexandra

Charles,

there was a recent thread on vitrectomy in sci.med.vision. Maybe it's still there-- you might want to check it out. It was related to the problem of floaters, so look up under "floaters." There wasn't a lot of info, but what I remember is this.

In vitrectomy, they replace the vitreous with the saline solution, something into which the vitreous tends to gradually turn anyway in the course of natural aging. However, in about five years after the replacement, all patients develop cataracts. Because the rate of cataract surgery success is very high, this is not considered to be a counterindication, but, rather, a follow-up procedure. They won't do it for a non-threatening (albeit annoying) minor problem like benign intravitreal floaters, though, and someone in sci.med.vision was really upset about it. So cheer up -- at least you're getting something other people want but can't have!.. I wish you the best of luck and a complete recovery.

Elena

>publications they were?

>

They were WWW articles that I found using a Lycos search. One of them is an article by Robert Bidleman at:

<http://www.crl.com/~robbee/bilart.html>

There were several others but that's the one that summarized the bunch for me so it's the only one I kept a bookmark to. If you're not familiar with Lycos, it's one of the best search engines on the Web, available at:

<http://lycos-tmp1.psc.edu/lycos-form.html?>

Just hop there and do a search for bilberry.

Another thing I found is that a lot of things are called bilberries that are not really them. One mail-order herbal place listed "huckleberry/bilberry" as an entry, implying they're the same thing; I did a Lycos search on "huckleberry" and found that there are 3 different genus of plants with several species each that are called huckleberry; none are the same species as bilberry (*Vaccinium myrtillus*), although some are in the *Vaccinium* genus.

(But there can be a huge difference within genus: which would you rather be locked in a room with, Felis Leo or Felis Cattus? :-) Caveat emptor...

It's kinda night time right now. I will definitely try it tomorrow. How often/how long do you do it? Also, forgive my ignorance, what is homeopathic Euphrasia officianalis (a.k.a. "eyebright")?

Thanks

> often/how long do you do it?

The way I was taught to sun is to face the sun with my eyes closed and move my head (and eyes) in a counter-clockwise circle around the sun. I do this at least once a day for ten to fifteen minutes. When I was starting out, I would do two or three five-minute sessions per day and palm for five minutes immediately after. If you find that your eyes are too sensitive for regular sunning, you can work up to it by doing the same exercise facing the sky but not the sun.

> Also, forgive my ignorance, what is homeopathic
> Euphrasia officianalis (a.k.a. "eyebright")?
>

Homeopathy is a type of medicine that helps you overcome illness or injury by bolstering your immune system, rather than suppressing it, as is the case with conventional (allopathic) medicine. You take miniscule doses of something that, in larger doses, would cause the symptoms that you seek to prevent. It sounds kind of off-the-wall but it works amazingly

well for a variety of conditions. I found that taking homeopathic Euphrasia when my eyes first started watering, relieved the problem within about half a minute.

As to where you might buy them DownUnder...I haven't a clue. Perhaps some of the Australians that read this list can help there. I first encountered homeopathy a few years ago during a trip to the Netherlands, where this type of medicine is very common. IT is much less common in the US. I find the remedies in natural food stores and some pharmacies. Perhaps, if there is a physician in your area that practices homeopathy, he or she could give you a hint.

Good luck!

Amanda

Yeah, you may want to watch that computer use for a little while. I have found that I am much more susceptible to computer eye-strain than I was. Of course it may just be that I am more aware of it, as I become more in tune with my vision and my body.

```

```

Yes, having the class is definitely helpful. It is still up to the individual to develop a life-style that is conducive to clear vision. We are able to learn from one another's experiences and that is helpful. I agree that this list is a great resource to have. It has become particularly active recently and that is wonderful.

What impresses me about Janet's book is that, as I work through my myopia and astigmatism, I am constantly finding things that pertain to where I am RIGHT NOW. I bought that book eight months ago, read it and thought I understood everything that she had said. As time passes and my vision improves, I find things in that book that apply, in different ways, to a new vision student and also to someone who has been doing this for a while.

>
> When you palm do you visualize movement or black?

It kind of depends on my state of mind. I had a lot of difficulty learning to visualize at first. I taught myself to imagine color first. I would say "blue" and try to see the color blue. At first I would just get a very brief flash of something that may or may not have been blue. I would just support that and keep trying with different colors. When I got to the point where I could call up any color at will, I moved on to objects. Now, I sometimes visualize myself in a pleasant, relaxing environment. Other times, I just relax and observe the darkness.

I defintely agree. I draw an analogy between poor visual habits and eating junk food. IF you lived on a steady diet of chips and pop, you wouldn't be surprised when your health began to fail. Likewise, poor visual habits can lead to unhealthy vision. By learning better habits and applying them to your own lifestyle, you will be doing your exercises without even realising it. Everything that you do becomes an opportunity to fine-tune your vision.

No way...I don't buy it. I live in northern Vermont and we see REAL cold here. I recently went out into -20 F and it was the clearest vision I have ever experienced. Cold air is great for vision. You just need to bundle up a little and keep moving.

> I find the ones I avoid tend to be the ones that I
> need the most . For instance the General Electric game is a struggle I am

> close to really getting it.

Yeah, there is one really basic vision game that I had a lot of trouble with at first. I had to give up on it for a while because it was creating a ton of stress and aggravating my astigmatism. For your situation, with the GE game, there are lots of other games that teach the same skills. Perhaps you would be more comfortable with one of them. If you actively dislike a game, it will be counter-productive to force yourself to do it.

I appreciated Dr Kaplan's recent comments on this game. It was interesting to learn that many other people had had similar experiences. I am glad that I listened to my instinct and tried it.

>

> Yes, this is important to be open to guidance.

I think it is also important to understand that we all have a great deal of un-tapped wisdom within ourselves. I think that my myopia represents a rejection of that wisdom. I find it very important to respect the more intuitive aspect of my personality and not attempt to rationalize every thought and emotion that I have.

> Some of this stuff about thinking about what was happening to you when
> you first got glasses kinda bugs me. Granted I daydreamed and drifted off
> staring into space in school. I got glasses when I was ten . Being
> nearsighted and going thru vision therapy makes my want to focus my sights
> on the future to be more extrovert ed and not to focus too much on the past

That is an important point. There is a distinction between brooding over an issue and accepting it. What you might want to try to think about is what could have happened in your life to make your subconscious decide that you did not want to see the world clearly. For many women, this has to do with issues that surfaced at the onset of puberty. What is important is to try not to get caught up in saying, "X happened in my childhood and now my life is ruined," and concentrating on the cruelties of life forever. That is as counter-productive as blaming your vision on genetics and believing that you have no control in the situation. I try to say, "X happened in my childhood. I reacted by blurring my vision. I am an adult now and I can deal with the realities of life. I do not need to insulate myself in this way." I have a lot of respect for my subconscious for choosing such a benign way of trying to protect me from what it interpreted to be a dangerous situation. I have a dear friend who is a paranoid schizophrenic. He has 20/20 eyesight but lives in a fantasy world and believes that he is being haunted by dozens of supernatural beings. I feel very sad for him that his subconscious chose this way of dealing with unpleasant situations in his life. He reminds me that myopia is not such a terrible condition.

> . That is what is so weird about the exercises, for instance palming what
> an anti-social thing to do. And not wearing your glasses, well I feel more
> open but not being able to see peoples expressions makes it tough I find my
> self avoiding eye contact sometimes. It all makes me more determined to see
> this thru and keep going .

I feel that before you can really know the world, you need to know yourself. That is what palming and a lot of the other exercises teach me. I find that the heightened self-awareness that I gain through palming and meditation helps me interact with the world in a more loving and open manner. I have learned a lot about interpreting body language, something that I was totally unaware of previously. I have also found that I have to reach out and bring people into my space. That is something that was very frightening to me at first because part of my myopia is just about me being in my space and wanting to ignore the presence of everyone else. Bringing people closer to me in space has been a rewarding experience in terms of helping me deal with my own myopic thought patterns.

> Best of luck to you I've rambled for way too long.
> alexandra

Good luck to you too!

Obtaining an Eye Chart

- *Subject:* Obtaining an Eye Chart
 - *From:* "Linda" <llee@comox.island.net>
 - *Date:* Mon, 15 Jan 1996 17:39:12
-

To the person who posted the note asking how to obtain an eye chart:
(sorry, i lost your note)

You can order eye charts and other vision enhancement devices from Dr Kaplan. His e-mail address is Beyond_20/20@sunshine.net

He has a catalogue of all kinds of neat stuff, although you might find the shipping expenses to be a bit steep for just a chart. Anyway, i'm sure he would be happy to send you his catalogue.

Personally, i got my chart from my optometrist. She was a bit surprised that anyone would actually want one, but after i explained what i was doing, she was okay. It took a few days, cost about \$10 cnd, plus shipping.

Also, could someone please tell me if this forum is monitored? I sent, or at least tried to send a message a few days ago, but i haven't seen it. I wonder, was it not received, or are some comments screened out?

I really enjoy reading everyone's comments. I have been working on natural vision therapy for about four years and was beginning to think i was the only one in the world. Lovely to learn there are at least a few of us.

Linda Lee
Vancouver Island, Canada

found a cooperative in germany which is selling bilberry tea & bilberries themselves (dehydrated).
these products are strictly monitored for residues after the germn laws for medicaments.
as these bilberries are collected from wild grown ones i do not know about their level of radiation (tchernobyl) though.

50g tea: 3.50DM
50g b'berries: 4.90DM

tee & kraeuterladen
wurzacherstrasse 12
88339 bad wurzach

Good question. The optometrist never said that I have a problem with my near vision and always thought that not being able to read the computer screen was normal because I've got -3.25. Well the screen is 20" away from my eyes and I'm writing this message using the Arial font with a size 10pt. If I remove my glasses I just can't read it.

Tiny white flying things...

- *Subject:* Tiny white flying things...
 - *From:* "George Tohme" <PolySoft@msn.com>
 - *Date:* Tue, 16 Jan 96 05:50:51 UT
-

No I'm not talking about UFOs or other extraterrestrial things. Let me explain:

Today I wanted to start sunning but it was cloudy (yeah, talk about summer down under!) so I closed my eyes and faced the white clouds. 10 seconds later I started 'seeing' some very small very white dots dancing in all directions and then disappearing.

To give an idea of what they looked like: if you've ever watched the news when they show a war zone at night and there is some heavy shooting, bullets travelling in a not-so-straight line, well that's what it looked like except that it looked as if I was looking at he bullets departing from 'my head' and they were white and more agitated.

I was able to see them everytime I repeated the exercise. Does anyone know what they mean (if they have a meaning)?

thanks

GeorgeFromDownUnder.

Buying an eyechart

- *Subject:* Buying an eyechart
 - *From:* stefansi@ctrvax.Vanderbilt.Edu (Stefan Ivanov Stefanov)
 - *Date:* Mon, 15 Jan 1996 23:57:31 -0600
-

To all who offered their helpful hints of how to obtain an eyechart - thank you. I bought one today from the medical bookstore at Vanderbilt University for \$7.65.

I needed the chart because I didn't seem to have a good "benchmark" of my vision at home. I have such "benchmarks" - letters on posters on walls, book spines, road ads, signposts - in places I usually am or pass through, so I always have an idea how my subjective vision is at a given moment.

Peter Locher wrote in a recent post:

>I really would like to respond generally to letters like this.
>Often in this group I see (often incorrectly written) spectacle
>prescriptions but I rarely see anything like visual acuities.

>
>If any of you actually do have improvements, I would like to know

>if these were taken by your vision care specialist - either an
>ophthalmologist or optometrist and not with your own letter chart where
>your memory and hopes would reduce objectivity.

I agree. In Bulgaria (where I am originally from) I used to pop in at an optometrist's office and just have my objective refraction measured by autorefractor (I am aware that they are not very reliable although in my case measurements proved to be quite consistent). I noticed some significant variance between measurements taken by different makes of autorefractors however, so I decided to stick with one type - Rodenstock. I checked my vision this way quite often - sometimes as often as once a week, but usually once every two months. It cost me a nominal \$2 since I didn't see the optometrist for a full exam; plus the risk that assistants might think I am a maniac (maybe I am, at a point I was thinking of buying a refractor but it turned out I didn't have enough money in the bank).

So I now have a pile of printouts for the last two or so years. On each printout I have marked any specific conditions that might have affected my

visual acuity at the time of taking the measurement (eg stressed from work, light like a feather after something good has happened to me, weather conditions, etc.)

Regrettably, I have been unable to continue this practice in the US. I shelled out about \$80 for an eye exam two months ago and for now this price prohibits frequent check ups.

My special thanks to Dr. Robert-Michael Kaplan for his offer to supply an eyechart. I read his book "The Power Behind Your Eyes" "at one gulp". I shall be contacting him privately and if something worthy comes out of our correspondence we may share it with I_See.

Stefan Stefanov

I really would like to respond generally to letters like this. Often in this group I see (often incorrectly written) spectacle prescriptions but I rarely see anything like visual acuities.

If any of you actually do have improvements, I would like to know what your unaided visual acuities are. It would enhance credibility if these were taken by your vision care specialist - either an ophthalmologist or optometrist and not with your own letter chart where

your memory and hopes would reduce objectivity.

So if you have case histories where you have before and after histories I really would be interested.

e.g.

Patient XX

Age 25 at 1 Jan, 1990

1 Jan, 1990

6/24 R -1.50/-1.50 x 180 6/6

6/24 L -2.00 DS 6/6

1 Jan, 1996

6/7.5 R -0.50 DS 6/6

6/6 L plano 6/6

Even longer histories would be great including Diabetes and/or stress levels or drug use.

I'm sorry if I offend some people but I find some of the accounts here too subjective to be useful - or even believable. Please tell me exactly how much improvement you get.

I've seen the small white dots that dance like vibrant energy forms in the sky. I can see them better on cloudy days. I do think they are external, but I don't know whether it is useful to ascribe any significance to them. I always see them with my eyes open.

How were you feeling when you saw them?

I would really like to respond specifically to letters like this. I recognize your interest in case histories. I think we all share a similar interest. However, I also enjoy notes such as the one to which you seem to have taken offence. My personal criteria for vision improvement are subjective and intuitive -- it's my experience after all. A delusion of objectivity (measurement is an inherently relative phenomenon), makes for better comparisons and conversations; but in the U.S., the cost of consulting an optometrist prohibits frequent visits for most. I would not ask anyone to wait until they've seen an optometrist to share their experience or ask for encouragement.

The letter you responded to does mention an experience with sufficient veracity for the person posting it. That's good enough for me. It might have been helpful for you to suggest that if that individual still wears glasses, the experience might indicate a need to pursue a lighter prescription. Perhaps not.

Anyway, may you have an magnificently enthusiastic week full of profoundly positive and transformational experiences.

I don't think these are floaters. I see millions of them, but only when I'm looking at the sky on a cloudy day. On sunny days, I might catch a few, but they seem sparsely distributed. I am not assuming that there is a physical cause or a "material" object corresponding to the sensory impression.

(Do you think it could be a transubstantiated form of Elvis?)

I am happy to report I went to have my eyes examined yesterday and there was an improvement from my last prescription. My last prescription was: R -5.50 L -5.75 .25 180

My new prescription to see 20/20 or 6/6 would be R -5.00 L -5.00 .25 180. I have been doing vision improvement exercises for about three weeks on my own from reading various books and the FAQ from I-SEE. Needless to say I am excited and ready to push on with this project. I am picking up some transition glasses today which will be -3.50 for both right and left and no correction for the astigmatism. I hope this information helps you. I am not an optician just a wearer of glasses.

If I put on my last pair of glasses now I get nauseous. I've had a few short clear flashes were I look up and I can see clearly something I normally can't, they last several seconds then fade.

Being so aware of your vision is great really makes you want to get
outside and scan around blur or no blur. Being an artist I've always been
very observant this just enhances that.

>> I wish it wasn't so cold all I wan't to do is sit in the park or go to
the

I knew I would here something like this. :) It was 40F yesterday which is
down right warm to you. Its the moving thing thats hard if your drawing you
kinda need to sit down and spend sometime with a subject. Yesterday I
thought maybe i should take some photos instead. Could be interesting. What

would be in focus? Anything?

I have also found
>that I have to reach out and bring people into my space. That is

>thought patterns.

This is great . I can relate to what your saying. I look forward to looking
into peoples eye without anything coming between us.

>Good luck to you too!
>Amanda

Thanks. I have some good news to report. I went for an examination
yesterday. I have improved!!!! :) My last prescription was R -5.50 L -5.75
.25 180.

(I think in an earlier post I had reported it to be R -5.00 L -5.25 .25
180 that was a prescription from 1990)

Well my new prescription to see 20/20 is R -5.00 L -5.00 .25 180. So I
seemed to have evened out my eyes. I am very excited. I must admit if there
hadn't been an improvement I would be disappointed. My transition glasses
are -3.50 each eye no correction for the astigmatism. I am going to try to
wear them only when truly necessary.

I call them "Our Version of The White Diamonds, or Liz Taylor, Eat Your Heart Out!" I see them when I'm very relaxed, and they usually signal good times for my vision. Could it be that they are actual quanta of light? Far as I know, human eyes are capable of detecting the presence of as little as 11 quanta (theoretically, even one, but that's where relativity kicks in -- there's a statistical uncertainty as to the fate of a single quantum falling on the retina, it may or may not excite a receptor).

Weren't floaters once believed to be a sign of insanity? Actually, I think that many myopic people get them. I have no idea why though. I have seen something similar. I see white ones in the morning, when it is sunny, and black ones at night, when I am tired. They seem to be related to stress. I find that if I make an effort to relax and not try to look directly at them, they seem to go away on their own.

I will be interested to learn what effect, if any, vision improvement has on your art. I always saw myself as having no artistic ability whatsoever. Since I started working on my vision, I feel more interested in art and have even become motivated to create some of my own. I am actually starting art classes in a few weeks.

Good lord! I wear SHORTS when it gets above 35 F! I love going to Connecticut and freaking out my family by doing that. I wore shorts to Thanksgiving dinner. Everyone thought I was ill.

Actually, photography is the only ability that I have that remotely resembles artistic talent. I have been taking photos the entire time that I have been working on my vision. It is interesting to look back at the ones that I took last summer and see how my relationship with the world has changed.

Definitely, and being able to look directly at people, without glasses or contacts getting in the way is amazing. I now see so much beauty in people that I have never noticed before.

Good for you! Thank you for sharing. This is fantastic! There is nothing like experiencing a serious improvement to keep you motivated. I hope you keep it up!

I would suggest that those of you who are interested, find a user friendly Optometrist or even an Optician who would be willing to work with you on an experiment. Make an arrangement with them for you to come in after their busiest hours, where you can have them do the visual acuity findings. It shouldn't take that long to measure your visual acuity on their chart and at least every measurement will be standardized to their examining room. In

my case, I found a local optometrist (I no longer test eyes), met with her and arranged for my client to have her glaucoma measured once per week to monitor the natural approaches to her self-healing program. Otherwise, use the ole Snellen or Eye C chart from my books. They are logrithmically designed and reliable and accurate.

Cheers,

Hello,

I have tried the exercise described in the FAQ [9.4] for restoring the central fixation and I'm just not getting anywhere. I simply cannot find a point that will make the letter (or point) appear clearer. Is there another exercise or variation that will achieve the same objective.

thanks

This is wonderful! I wonder if anyone has explored this side effect of vision improvement.... I started weaving shortly before I started working on my eyes, and now I'm really getting into creating and weaving tapestries. Maybe we can *see* our creative side more clearly?

And congratulations, Alexandra, on your improvement! Now I really can't wait to get my vision officially checked. Still looking for a sympathetic optometrist in my area....

Objective Vision Results

- *Subject:* Objective Vision Results
 - *From:* "Linda" <llee@comox.island.net>
 - *Date:* Wed, 17 Jan 1996 00:52:57
-

In response to Peter Lochner's letter, i would like to list the various prescriptions i have been tested at since i have been working on improving my vision. The beginning results represent glasses that i had been wearing for about two years. I began vision therapy in June / 91(age 36) and my 20/20 glasses at that time were:

June / 91	R: -7.5	L: -6.75	Astig: (r) -.050/ 40 (l) -.050 / 146
July 2/91	-6.75	-6.75	
July 12/91	-6.25	-6.25	
Sept 14/92	-5.5	-5.5	
Mar /95	-5.75	-5.5	

My astigmatism remained the same throughout. These results were all recorded at my O.D.'s office during regular office visits. I schedule a visit whenever i begin to feel annoyed at my glasses. I am normally fitted for 40/20 glasses, an reduction of about 3/4 a diopter. At the moment, i am wearing 40/20, R -5.0 and L -4.75.

As you can see, i made quite a lot of progress in the first few weeks and then kinda fizzled out. However, i am not discouraged and am even more enthusiastic since i have found this group. My personal approach is more emotional then behavioural, but i think we are all doing what works best for us.

I attribute my first big acuity achievements to my taking up meditation. I go through spells where i work daily with an eye chart, visualizations etc, but then i let it go for a while. I too have flashes of clear vision - one second i am looking at blur and then, for a few blinks, the entire chart comes into clear focus. This never happens in my Doctor's office!

I notice that the vision i have now is the same as the prescription i

began with, in other words, within a year of wearing glasses (at age 13), i was wearing -5. My personal belief is that the majority of my fears were developed when i was young and have been in place longer. Perhaps it will take me longer to unfreeze that part of my vision.

I have recently started to do the swing ball exercise, thanks to so many in the group who recommended it. I tried this game many years ago and never saw anything move. As i watch the ball now, i can see some movement in the background. I think that i must have frozen my environment visually in order to control it and therefore survive. Lately, i am focussing on letting go of my expectations of how others should act. I am sure this will be a visual break through for me.

I understand your need for objective results and i thank you for your open minded approach to this somewhat radical method of visual and personal healing. I am not a diabetic, eat a moderately healthy diet and have until recently used drugs (alcohol, pot, tobacco) recreationally.

In response to Amanda's note, in which she asks if any of us have become more artistically inclined since changing our vision prescriptions:

About the same time i discovered natural vision therapy, i also became involved in theatre. At first i used to do back stage stuff, doing the myoptic sidelines thing but that is changing. I have recently joined a musical theatre group and am having too much fun. I enjoy very much being on the stage, something that had always frightened the life out of me before! Sometimes i hear someone say something like, - oh no, i don't want to be centre stage, just leave me back here in the chorus where no-one can see me - and i think, hey, i used to do that. I can't for the life of me imagine why! What could i have possibly been afraid of?

Blessings to you all.

I am going to second this reply. when your eyesight improves, you can tell, you dont need to have an optometrist verify it for you. most people arnt intrested in doing a double blind study on themselves, but only interested in results. and again I think you want to question the veracity of the claims, this clearly serves no usefull purpose.

Marla,

Thanks for mentioning orgone energy. To speculate: perhaps orgone energy is easier to see on cloudy days because of its lower vibratory rate. Now I need to start looking for it on bright sunny days. I didn't know that full spectrum bulbs could freshen orgone energy.

I do use sage and cedar from time to time to clear out the unwanted energies. It freshens the rooms and lifts my spirits. I have been reluctant to use the orgone terminology because I'm not sure that the orgone model encompasses all the energies that can collect here and there.

Mark

As a professional, I would be crazy not to pursue a "discovery" in my field of study comparable in magnitude to the VT "discovery" in the vision field. I as a professional would WANT to study the cases, do my own experiments, and verify the results for myself.

It seems like most vision professionals are really "lazy" in this respect. The only thing they do is demanding that the patients PROOF that they're not lying. They ask the patients to perform scientific experiments for them. They want the "objective" results to be HANDED to them on a golden plate, as if their continuing mockery of VT was objective. In short, they refuse to do anything to participate in the "discovery".

The closest participation I have read is a doctor(?) who bet money to cover his own laziness (I won't mention any names, but his initial is Bill. Hey Bill, did you part with your money yet? Haven't heard from you for a while), and others who mock VT instead of studying it to see if it really works.

In S.M.V., we have doctors who mock us commoners when we make "false" statement about how VT works. Correct me if I am wrong, but isn't it the duty of eye doctors to study these cases?

We commoners don't know HOW it works. We don't care HOW it works either. The only thing we care about is that it DOES work. It is the duty of the so-called doctors to figure the inner working of VT. If VT results are just psychological(sp?) effects, so be it. The only think I ask for is that you self-proclaimed doctors fulfill your oath and do your duty and study the cases objectively. Do not brush aside VT just because "you know better" and "you don't think it would/should work".

In closing, I have to point out that only in vision field have I seen doctors asking patients to perform scientific works to convince the doctors of a break-through discovery.

Perhaps the standards for graduation in vision fields are not held as highly as those of other scientific fields. If this was the case, I will understand the lack of interest in studying VT, and doctors asking patients to perform

scientific experiments to proof their claims.

This is in response to several recent discussions at once.

Re double postings: one (ONE!) of them is mea culpa -- I've accidentally clicked on the "send" button when I intended to respond to someone's post -- AFTER I copied it but BEFORE I responded. Sorry. I've been afraid of computers and little green men for much of my life, and I've come to terms with little green men lately but am still struggling with computers.

Re little white things: the dancing sparks of light aren't floaters. Those of you who do have floaters know what I mean -- they are totally different, and ugly, too. Please share experiences. I'm particularly interested in any difference in their perception after you've started vision therapy.

Re vision improvement and the arts: I'm writing a sci-fi story directly inspired by this group.

I've also tested myself on the visuo-spatial section of the IQ test -- the section where, in stark contrast with verbal and numerical tests, I had scored brain-dead a few years ago. This time, however, I got a decent 140 on that particular section. The dead zone is gone.

what is this the new age brigade is here in force?

what the f* is this orgone energy nonsense.

you can see tiny white specs at any time if you look for them.
you can see them even when you close your eyes.

its almost certainly random firing in your neural net of a brain.

if if you look at anything closely enough you can see it shimers,
again thats your brain hard at work making a picture for you.

stick to know facts when improving eyesight.

you have to remember everything you see is in your head, and not out there. different people see diferent things.

Is there really a need to be condescending? There was a time when the fact that the earth was round was considered "nonsense."

And as to sticking to "facts," your facts may very greatly from someone else's facts, and we must each do what feels instinctively right for us. It's this loss of trust in instinct, and a mindless belief in what others call facts which have shaped modern medicine into what it is.

No one is on this list to be belittled or ridiculed, and I, for one, would appreciate a bit more respect to be shown to all who express their opinions.

Thank you,
M. Antonsanti

Weaving? Wow, that is really interesting. My mom used to be involved in weaving. She has a loom that had belonged to my great-grandmother. It takes up an entire room.

The way I am looking at my recent artistic endeavors is that I have these abilities that I have repressed for years. I am beginning to see the creative part of my personality as being just as important as the intellectual part. I really had to let go of the impulse to judge the finished product and just enjoy the act of creating.

Glad to hear your taking classes just remember there is not right or wrong when creating. I hope you are inspired by your class.

I used to be the same way. I was a photography major in Art school. Simply because I thought I couldn't draw. I'm slowly learning I can draw. So far my paintings have been primarily abstract but I think that might be changing soon. Have fun with your art class and try not to compare yourself to others just explore. I hope I'm not sounding too preachy . Its just that there are good teachers and there are not so good teachers. I think everyone has artistic abilities but many people had them squashed at some point in their childhood.

Actually I went back yesterday to pick up my glasses and cornered the optician he had been so weird the day before that I left feeling uncertain about my prescription in fact the only reason I knew my prescription was from reading his scribbled out numbers on my card. You see while talking to him it was as if he did not want to tell me how well I had done and was very evasive in his communications with me So yesterday I said could you please explain my reading to me again and write it down for me. Well it wasn't -5.00 on each eye it was -4.75 each eye and the astigmatism was so weak he said he might not have corrected for it. So I have improved even more than I thought !!! What a yucky experience it has been dealing with this store. The owner is even worse, giving me a hard time. He has it in his head that I'm only training myself to see 20ft in front of me. Don't know where he gets that from but ... whatever.

Thanks for listening.

oh, one more thing. Tell me a little about the photos you've taken. How blurry are they?

Do they look different than what you thought they would look like when you snapped them?

I was that way until I moved to Vermont. (I grew up in Connecticut.) I think it is all just a matter of what you are used to. I had an idea to get you outdoors, though. How about trying to play with a Frizbee? Frizbee in the blur is a blast.

I understand and agree with what you are saying. Actually, the course that I am taking is part of my university's not-for-credit extension program. My Natural Vision Improvement course last summer was part of the same program. Technically, I am not supposed to take those courses. They are supposed to be only for "grown-ups". No one has ever said anything about it though and they seem more than happy to take my money.

Anyway, the course is called "Art for the Intimidated" and it is limited

to non-artists. I have met the teacher and she is great. I am hoping it will be a little more open than the kind of art classes that I hated in public school. You know, where someone else told you what to paint and it was more like you were expressing the instructor's creativity than your own. I think that a lot of people get turned off to art that way. Either that or you end up thinking, as I have for most of my life, that art is something that has nothing to do with your life or that you aren't the type of person that can "do art". I agree with you that everyone has creativity. Sometimes it may simply be a matter of learning to access it. (Gee, I didn't know I had that much of an opinion about this.)

The course meets once a week for 8 weeks and starts next Wednesday (gulp). I will try to remember to let you know what it is like, if you are interested.

I have found that there are certain people that, no matter what you do, are always going to come up with some reason not to believe that your vision is improving. It is too bad that they have to be so insecure about this stuff. I just keep reminding myself that it is their problem. I know it is frustrating but do try not to take it personally. You are doing this for yourself, not for him.

> oh, one more thing. Tell me a little about the photos you've taken. How
> blurry are they?
> Do they look different then what you thought they would ook like when you
> snapped them?

The photos are...um...different. I don't always have much of an idea what they are going to look like when I am taking them. I try not to bring a lot of my own expectations to them or get too hung up on doing it "right". I tend to look at them as an expression of where I am right now. I know that I have far to go, in terms of my personal development, and my photos do too.

Some of them are just really, really "bad" by conventional standards. I guess some of my more recent photos are pretty well focused. I sometimes see a little more clearly through the view-finder than I do in real life.

There have been a couple of really interesting ones, where something other than the subject of the photo is in focus. In general, I would say the photos reflect my view of the world. I have to confess that I have been known to force a clear flash, just to be sure of getting a particular photo the way I wanted it. Those are usually photos of family that I am taking for someone else.

Thank you for sharing your interpretation of your vision. I am intrigued
by your comments because i didn't realise that different people perceive
swing ball differently. When I do swing ball, I see lots of motion in the
background. It feels like lying on my back in the bottom of a canoe in
rough water but with none of the feeling of vertigo that one might expect.
It is among the most comforting and relaxing things I have ever
experienced. I find it positively euphoric.

I posted a message asking for help finding succus cineraria maritima which the i_see faq recommends for cataracts.

I received this response. Although it sounded fishy I did do it just on the offchance that it was real. It wasn't.

I am very upset about this (and I'm cancelling the I_see listserve group in the message after this one) because I thought this was a SERIOUS listserve group where people try to help each other so wasn't prepared for folks to use it for jokes.

But I do want to thank Alex, Vic, Betty, and all the other wonderful people here who have bent over backwards trying to help people. I really do appreciate your great kindness and am sorry that nasty people instead see this list as a way to play tricks. Thankyou again.

Here is the message as I received it:

I have little black, specky things when I am tired or under stress. They tend to follow my eye movements. I haven't seen them in a long time, however. Since I started VT, I have learned to relax and make them go away.

In the last few weeks, I have seen white, blobby things that I had never seen (or noticed) before. I have only seen them on sunny mornings and palming seems to make them more noticable. They remind me of the "honeycomb" effect that I used to get from light reflected off snow, back when my eyes were very light sensitive. (I was a sunglass addict before I started VT.)

Does anyone have any stories to share about their work with presbyopia therapies? And is the natural vision therapy very similar to myopia therapies? I'm very interested in your personal stories whether you worked in tandem with a therapist or on your own. Please tell me what worked best for you.

Thanks in advance,
freda

Look up the definition for "improve," will you. Then again, If you break a
bone, I can improve your condition with a painkiller, and I can prove it.

>No offence is intended. I just want a MEASURE of objectivity.

>

Seven months ago, I refused to drive in my -7D contacts because they had
been prescribed for 20/40 a couple of years before and I no longer saw any
signs on the highway wearing them. I had to ask people for rides because I
knew that driving with this kind of vision was lunacy. Now I drive in my
old -5,5D glasses and, while waiting at the red light, read a piece of a
newspaper lying by the road. And you're telling me there's a fair savior
knight with an ophthalmoscope in this universe who will tell me OBJECTIVELY
whether that's an improvement or not.

Hi, Alexandra!

Yes -- I'm over in Brooklyn. I'm still trying to find someone local who's involved in vision therapy. The closest I've come is an optometrist in New Jersey, near my brother-in-law. I'll probably be going there next month for a visit anyway and am planning to get my eyes checked then! I think it'll be nicer to actually see an optometrist who believes vision can be improved rather than have to keep explaining myself. It gets old after a while...

If I get tired of waiting, though, maybe I will take a trip over to Manhattan and see what kind of reception I get at Eyeworks -- could be fun!

If anyone out there knows anyone closer to Brooklyn, please tell me....

Karen Yang

 - *From:* "Linda" <llee@comox.island.net>
 - *Date:* Thu, 18 Jan 1996 00:55:56
-

In response to your comment regarding middle aged shift from near-to farsightedness:

I had heard that comment before from one of my non-believing friends but he didn't have a source for it. Since turn around is always fair play, have there been any studies on this? Certainly my own doctor had never heard of a reversal in prescription and she's is fairly up to date in her field.

I do have many friends that have gone into bi-foculs at around 40, but this is not the same thing, is it? If such a phenomenon has been noted, i would ask you whether these people had any other changes in their lives? Fortyish is certainly a time for re-evaluating and changing focus (pun fully intended). Besides, if vision is reliant on the shape of one's eyes, then where is the medical rational? I mean, you can't have it both ways ... vision is fixed by genetics, unchangeable except of course, until it changes at 40 for no particular reason ...

You might ask why a person such as myself would continue after 4 1/2 years to seek perfect vision when it flies in the face of everything we 'know' about eyes. Go on, ask me . . . well, i'll tell you anyway!

When i first read about the changeability of vision, it was in a 'channelled' book - i admit it, i am a confirmed flake, just a few degrees left of 'way out there'. After reading that all physical conditions are a manifestation of our own belief systems (still with me?), i learned about the Bates, or more specifically, Kaplan's method.

During the first few days of Kaplan's 21 day program, i had what i thought was a flash of clear vision, but i now view it differently. I was walking my dog one sunny afternoon without glasses, when all of a sudden i could see the world in startling detail. Certainly the

colours were brighter, but the depth of field was what really moved me. It was like i had always seen the world thru a window and this was what it really looked like, multi-dimensional and in motion. The vision lasted until i had the thought that i didn't deserve this much pleasure. A huge wave of saddness landed on me, that i have yet to name and my sight returned to 'normal'.

If that is how sighted people see, then that's what i want. It wasn't like seeing the eye chart clearly, it was much bigger then that. And i had no explanation for it. My eyes had shifted more then 6 diopters in seconds and back again. Everything i had learned about 'how things work' told me it was impossible. Even Kaplan / Bates et al say that improvement is gradual, the result of work, nutritional adjustments and exercise. And yet all i had done was change my mind to believe that it might be possible . . .

So, i keep trying. Even if everyone else tells me it's impossible, that i can't go around changing my body parts just because i want to, i know that i can. Even if i have to confront and eradicate every bit of fear and sorrow in my psyche, i want to see the world as it is, and not flattened by some artificial device. Or is it me that does the flattening?

I'm sure my experience is not unique. Has anyone else got a "i remember the first time i saw clearly" story? I would love to hear it.

Hang it there, you're doing great!

orgone shmorgone

- *Subject:* orgone shmorgone
 - *From:* Vic - Deus Ex Machina <root@spook.cia.com.au>
 - *Date:* Thu, 18 Jan 1996 18:29:35 +1100 (EST)
-

I look up orgone in current medical diagnosis and treatment. 1995 edition. a hefty tome that covers every know problem and possible cures. nothing.

ok. I have a lot of books on my shelf. lets try Alternative medicine the definitive guide. a huge book, that covers borderline resolutions to problems.

nothing.

ok I have more. Optima encyclopedia of Natural medicine. oh what a surprise. nothing. and on and on we go.

what is the point of introducing some obscure jargon, which nobody has a clue what it refers to when there is already a perfectly good vocab available to us to talk about health and healing.

let me tell you about orgone energy, many years ago a prominent australian racing driver was sucked into the orgone energy bandwagon. some kook convinced him that the orgone energy in his car wasnt setup correctly, and that by placing a black box under the car it would realign the energy and make his racing car go faster. this racing identity tried it and was sold. he had a deal with holden australia to produce aftermarket version of family cars, and was making a tidy bundle out of it. so he insisted that his aftermarket cars be fited with this "black box". holden was sceptical. the originator, some pseudo-scientist wouldnt let them analyse the box. holden wanted to do trials. and after much arguing they found objectively that the cars acutally went slower. (because the originator insisted that the tires needed to be let down a little to balance out the energy.)

anyway to cut a long story short, the driver eventually woke up to himself and realised he had been taken for a ride.

I wont waste any time looking into the life and works of Reich and seeing what a lunatic this guy was. freudian psychonalysis itself is virtual unheard of today. it has been discredited by countless trials.

I am forever amazed by the amount of rubbish that the new age is willing to adopt to make a buck. perhaps monsters from atlantis will channel messages of encouragement to us poor shortsighted souls.

I have no problem with different belief systems, I dont have a conventional belief system. I dont do mainstream things. and I will support people who dont want to have a conventional beleif system. BUT one has to draw a line between total nonsense and something unconventional.

I am bothered by well meaning people jumping to the defence of what is basically rubbish.

if you are shortsighted, it means one very simple thing. once you had, and may still have, a life style which was *incompatible* with long distance vision.

your eye has changed shape. thats the physical reality of the situation. no amount of praying to alah or chasing orgone energy around the room with cedar oil or chaneling venusian aliens is going to change the shape of your eye back to something compatible with distance vision.

YOU are totaly irrevocably responsible for your vision. YOU are responsible for the shape it is in now.

how do you change the shape back? YOU have to do it. nobody is going to do it for you, no magical mystical set of procedures will change your eye shape back.

there are two things that happen when you do VT. first you build a lot of new pathway to your eyes, you open up nerves that have been sleeping. this gives you the "delusional" aspect of improving. you can see better but the optometrist doesnt find any change in your eye. then later the second thing is that you begin the make actual changes to the shape of your eye. your unconscious mind that looks after you, that keeps your heart beating, your lungs breathing, day and night, week after week, year after year, it knows who I am talking to, "knows" how to alter the shape of your eyes. this is a "clear flash", when all blur evaporates and you can see perfectly. it is never a question of when you are "ready" to have a clear flash, it is a question of knowing how to do one.

just like knowing how to tense the cilliary isnt an issue of when you are ready to do that little parlor trick. it is a question of self knowledge.

no amount reading or praying is going to teach you to tense the ciliary muscle under voluntary control. only practice, concentration and paying attention to what is happening within yourself is going to allow you to learn to take control of an involuntary muscles like the cilliary. I should know I have done it.

let me tell you about my first clear flash. I had just finished doing this NLP course, and we did lots of work on the unconscious mind, and naturally enough I wanted to use that to improve my sight. nothing seemed to change, my eyes seemed more open but I wanst seeing clearer. then one day in frustaration, feeling self deafeated, I said to myself, to my unconscious mind that keeps my heart beating, my lungs breathing, that if it konws how to fix my sight it should do so NOW! and to my amazement I felt my eyes move slightly and a funny feeling came across my face and POW. perfect clarity. I looked around in total awe. everything was crystal clear, the colours were brilliant. I was shocked. unfortunately it lasted about 30 seconds. since then I have had countless clear flashes. it isnt a question of being "ready", its question of intention, intention to do it NOW! if you are not ready now, get ready!

why do clear flashes not last long? it seems your unconscious mind knows how to tug at the right muscles, and it can change the shape of your cornea very slightly. but simply tugging at muscles is only a short term solution, you cant keep tensing muscles forever to fix a mishapen eye. for each -3d of myopia, there is a 1mm lenghtening of the eyeball, that is a miniscule change. this is a tiny problem. but you have the interoccular pressure making sure that if your eye changes shape it wont shrink again in a hurry. so on one leg, change comes about from persistant, continuous, relentless dedication to living a lifesytle that is *compatible* with distance vision, and the other leg you need knowledge, self understanding, exploration, endless self-observation. and by walking on these two legs you can achieve permanent change entilery on your own steam. VT is exacly like learning to walk again. something everybody has learnt to do. from each tentative step, with concentration and keen observation on what is going on and perseverance you learnt to stand up and walk.

if that compatibility with distance vision means using an emotional metaphor to describe your relationship to your sight, then that is fine. if it means using a strictly physical basis to describe your sight, again that is fine. but orgone energies? please spare us.

Vic

No, it doesn't. There are no dates or medical history.
For example what is your age. At around 40 yrs of age there is often a
shift toward increasing long sightedness (Hypermetropia) which reduces
the prescription of shortsighted (Myopic) people without treatment.

My point is if you claim improvement I would like some objectivity.

This is a great start though. Thank you for raising the discussion
one level.

My response is that you "improvement"
is probably delusional.

What is your own measured improvement in visual acuity
or contrast sensitivity or colour vision.

I can improve vision with galsses very often, and I can prove it.

No offence is intended. I just want a MEASURE of objectivity.

My my, what am I getting myself into. Arguing with vic. Deus is gonna jump at me right out of his orgone-free machina, so help me. However...

>I look up orgone in current medical diagnosis and treatment. 1995 edition.
>a hefty tome that covers every know problem and possible cures.
>nothing.

>
<snip several additional hefty nothing sources>

New Webster's Dictionary and Thesaurus of the English Language, 1992
p. 840:

"Reich, Wilhelm (1897-1957), Austrian psychoanalyst known for his controversial theory of orgastic potency -- that emotions of love and the pleasurable sensations form the basis of mental health. He taught in Vienna and Berlin (1927-33). During the 1940s and 50s, in the USA, he maintained that orgone energy was the basis of life energy and invented the orgone energy accumulator, a device that was banned. When he defied the ban he was arrested, convicted and imprisoned. He wrote "Character Analysis" (1993) and "The Mass Psychology of Fascism (1993)."

Vic -- this last one is an absolute must read for you. You'll redefine your defiance.

>I wont waste any time looking into the life and works of Reich and
>seeing what a lunatic this guy was. freudian psychonalysis itself
>is virtual unheard of today. it has been discredited by countless trials.

>
Yeah, that's what I've heard -- under the circumstances that prohibited personal inquiry into a non-compliant ideology. But what a coincidence -- only last Saturday a friend of mine who is a shrink came close to physically attacking me when I casually remarked on the "Freudian myth" -- and I didn't even mean to express skepticism, I used the word "myth" in the sense of an

organized system of beliefs, a sort of cosmology. Well -- I guess in Australia they may have suppressed this particular cosmology, just like where I come from. They used to tell us it was "totally discredited," too.

Elena

If the clock strikes thirteen it doesn't only mean that the last ding-dong was a mistake. It also undermines the credibility of the previous twelve.

>...of science is wonder, along with
>curiosity to find the truth, not out of hand dismissal of ideas.

Spot on - many people who claim to think 'scientifically' in fact do no such thing. They seem to forget that science is **observation** followed by formulation of a principle which **describes** the observation, rather than an **explanation** of what's going on. It doesn't deal with truth at all, as such. You can't **really** dismiss ideas on the basis of science, because it **could** be that you just haven't observed the phenomena yet.

And people tend not to put much effort into looking for, or thinking about, phenomena which they've already 'scientifically' dismissed.

>again thats your brain hard at work making a picture for you.

Hardly very helpful "explanations" those. No real basis.

What is it about having your brain "hard at work" which would make vision "shimer". And if the brain really **were** a neural net, why would it randomly fire, and why would this produce tiny white specs?

>stick to known facts when improving eyesight.

It doesn't seem that there **are** many of those "known facts" going round. What **is** available are a few sets of different opinions, so why not use the approaches that are most useful, or work best, and leave

the rather foolish pursuit of trying to explain what is "really" happening.

If the idea of orgone energy produces some useful approaches that help, then that seems fine by me!

Hi Elena,

I've got the addresses of two. One seems to be more into diet and nutrition: Ben C. Lane O.D., CNS, FAAO, FACN, FCOVD (what do these things stand for?) at the Nutritional Optometry Institute, 16 N. Beverwyck Road, Lake Hiawatha, NJ (201) 335-0111. The other sounds like he's more into behavioral optometry, eye exercises, etc.: Dr. William Moskowitz at the Park Vision Therapy Center, 245 Union Avenue Suite 2C, Bridgewater, NJ 08807 (908) 725-1772. I'll probably try visiting the latter, since he sounds more like what I'm interested in.

Oh, yes, and my brother-in-law's address is...

But it also changes along with the hormonal changes in pregnancy and lactation and then improves again! My last ophthalmologist said that he has so far discovered that two women were pregnant before they even knew it just through unusually big changes for the worse in their myopia. (Supposedly vision gets more nearsighted in order to facilitate bonding with the new baby -- at least that's his theory...)

That's what really got me thinking that vision is not permanently fixed at any one level, and made me more open to explore ways to change my vision for the better.

NLP & long distance vision

- *Subject:* NLP & long distance vision
 - *From:* "Linda" <llee@comox.island.net>
 - *Date:* Thu, 18 Jan 1996 16:21:35
-

Vic, in response to your Jan 18 posting:

There were many interesting points in your letter and i would like to address a few. First of all, how can i get any information about NLP -- i think it stands for Neuro-Linguistic Programming. I have seen workshops offered in cities far from my home, but have not found any books on the subject. Truthfully, i haven't looked all that hard because this is the first time i have heard NLP mentioned in connection with VT. I would like to hear more about it, if you wouldn't mind. Can you recommend any books on the subject? Your own experience sounds very encouraging. I gather it has something to do with monitoring our own language patterns to reprogram ourselves?

I am also interested in what you had to say about choosing lifestyles incompatible with distance vision. I would like to hear more about that also. As i chat with more and more people involved in VT, i encounter an overwhelming preponderance of accountants (including myself) -- has anyone else noticed that? I can see how accounting as a career focuses on details, things close up, but how would that apply to decisions i may have made in early puberty. I don't remember ever daydreaming about accounting in my early teens, although i admit, i always liked the clothes! But how do classic cut, navy blue suits relate to a non-long distance lifestyle?

But then, i am being facetious! Actually, i can remember that having a steady supply of money was important to me. Perhaps that's what you mean by decisions incompatible with long distance. But doesn't stocking up for the winter imply that there will be a future? I suppose it could be a fear that i won't be able to cope in the future so i better grab it now. Is that what you mean? Is this an idea of your own, or can i read more about it somewhere?

Finally, i would like to thank you for sharing with us your story about your first flash of clear vision. Yesterday, i posted a similar story, that you may have read. The difference is that my flash came when i didn't in the least expect it, while you seemed to be able to will yours to appear! But i have had only a few incidences since then in contrast to your countless clear flashes. Still, the original one was the best. I guess its true, you always remember your first time . . .

. . . until next time,
keep the faith!

>in tandem with a therapist or on your own. Please tell me what worked best
>for you.

Presbyopia is my favourite condition to work with because I find the results occur really fast. I call Presbyopia the Short-arm syndrome for those of us over 40.

I am 48 this year and do not wear glasses for all of my reading, computer work and when my vision does blur I use half-eye pinholes as a training device. I focus my eyes in by crossing or converging them and then quickly release with an out breath. Miraculously the fine print pops into focus after about three breaths when I remove the pinholes. If I have editing to do , I use the pinholes and a full spectrum fluorescent task light put out by John Ott, called the Ottilite. Many of my presbyopic clients, as I experience, can read without any glasses while using this light. Next in my routine is to use the small eye chart, (Near Eye C -chart from my books), and focusing on the white space between the letters, I breathe in and trombone the card towards my eyes and cross them at the same time. This has a very powerful effect of activating the focusing mechanism of the eyes. =46or those of you who have Janet Goodrich's book, can see a similar description from her point of view.

I suggest my clients always use a weaker plus lens or less minus while working at the level of the Presbyopia. The less nearsightedness that others have talked about on another thread is the evolution of Presbyopia. I love this period of my vision life. I am learning so much about my physical well-being and how clear small print is up close. Hope this helps.

Much light,

Robert-Michael Kaplan.

Hello,

has anyone used/using saline solution (the kind that you use with contact lenses) to wash the eyes?

I still squeeze a bit in my eyes because it makes them feel better. Is this a good practice?

thanks

george

Ivo,
thanks for support.

To be honest with everybody, I don't give a rat's tush for OR against the subject matter of discussion -- it's just that the person who first introduced it has succeeded in improving HIGH myopia and therefore is a member of my own minutest minority on planet Earth. I have a special respect for its members no matter what their methods may be. You know, whatever takes you through the night.

For those who are interested in the subject matter per se, I should mention Dr. Rosanes-Berret, a New York-based natural vision improvement ophthalmologist and Reichian psychologist. In her book on VT, she attributes her first success in this field to Reichian analysis.

So we have been presented with three models for interpreting the tiny white things that some can see at certain times or all the time: Quanta (point-instant representation of light energy?); random neuron firings (highly speculative if you ask me [No one did; I'm just not convinced of the validity of randomness or entropy]); and orgone energy. All three are theories and look intuitively promising from within three separate interpretive paradigms. I don't know which is correct, if any. The orgone energy model is promising, in my opinion, because it speculates on the influence of the environment on our state of health in a way that is partially consistent with my personal view of the world as basically an energy phenomenon. This tiny white thing discussion may be irrelevant to vision improvement. I need to do an informal survey, but I would guess that many see these things regardless of their visual acuity.

Vic,

Thank you for expounding your views. I respect your point of view and second three important ideas contained therein: (BTW, I still think orgone energy is an interesting theory):

- a. Beware of black boxes (use your mind instead);
- b. Examine ideas carefully (even the ones you thought made sense);
- c. orgone energy does not have much to do with vision improvement.

Saline is a lot better for your eyes than commercial drops with chemicals
that "get the red out", and is cheaper too. Make sure that the saline
doesn't contain thimerosal or other mercury compounds, since mercury is
incompatible with living things.

Why bother with objective evidence??

You could help change the way vision care specialists treat myopia.

Why bother with that if you have found your way to deal with it and its working fine.

It opens the door to others, including children who are just starting to become myopic.

What is objective evidence?

There are two lines of argument why the Bates method or versions thereof are a load of crap in the eyes of those who control vision care.

1) People are only learning to interpret blur. Therefore it is not a real improvement in the refractive error of the eye. This means you can read the 20/20 line, your "visual acuity" is 20/20 but if one were to measure the refractive error of your eye objectively, with an autorefractor or retinoscope, you could still have a refractive error (that is a beam of light bounces off your retina and through all the parts of your eyes that bend it and it comes to a point of focus at a different point than if you had zero refractive error).

2) People whose vision improves just had an accommodative spasm, "pseudomyopia" and have learned to relax their ciliary muscle hence have eliminated this temporary refractive error. The spasm caused the lens of the eye to bend the light too much making a refractive error and once the spasm was eliminated so was the refractive error, no biggie, this is an established phenomena. For the majority of myopes this is not the cause of myopia (unless you get a reduction in refractive error and then we'll

conclude it was in your case, ruling out the validity of Bates ideas) and so trying to reduce the majority of myopia through exercises is a waste of time and money.

Want to address these with hard evidence and help change the face of vision care for myopia??

Get your optometrist/ophthalmologist to do an objective refraction on you..both have the means with a retinoscope..some might have an autorefractor...and have them do it while your eyes are fully cyclopleged (this is a drug which temporarily relaxes your ciliary muscle). If then you return to them and have them repeat this measurement after you have improved your vision with training and there is a significant improvement by this measurment bingo you have proven a true change.

Its that simple. I would be very happy to make a collection of these reports and get it published in an optometric journal that would be read by thousands of vision researchers, optometrists and ophthalmologists. Send the results or your vision care specialist name, address, phone # to me directly via email, to be sure I get it and cc I-see so everyone else can see it as well.

I am asked on this group what a visual acuity is !!!!

In simple terms it is a measure of how blurred your vision is.

It is usually measured using a letter chart and is a simple guide that anyone can use. It has its problems but is a good guide.

Colour vision - you had to ask ??????????

Contrast sensitivity is a measure that some - especially cataract patients will know. If you have cataracts and want to measure improvement you should get a low contrast chart to measure improvement as well as normal charts.

Over the past week I have been read complaints about my interest in objectivity in results of vision training. I'm sorry that some people feel threatened by this but anecdotal evidence is only so good and saying "I'm enjoying my vision better" as I find frequently here is not evidence of improvement.

```

```
> Does anyone know the arithmetic required to use a 20/20 chart in a
> ten foot room?
```

First of all, realise that there is no inherent "20" in an eye chart. If you stand away from it at 20 feet, and you can read the 20 line, and your vision is (at least) 20/20. If you can read the 15 line (lucky you!) your vision is 20/15, or "one-third better than normal" of If you can only read the 40 line, your vision is 20/40, or 1/2 normal. This figure, however, only applies to your vision AT 20 FEET, which is why the fraction is not normally reduced, and why the numerator is always "20". But this much everyone knows.

Now then, the same chart can be used at 10 feet, using "10" as the numerator of the fraction. At 10 feet if you can read the 10 line, your vision is normal or better. If you can read the 20 line, your vision is half normal AT 10 FEET, or 10/20, and so on.

Same for all the numbers of the chart. Each number means "the letters on this line are the smallest that can be read by the normal eye at X feet" It works out so nice because all the letters, viewed at the specified distance, project to be the same size on the retina, and if you increase your distance from any object by a certain amount, the image on the retina will increase by the same proportions. Thus, you will notice that the "20-foot" letters are exactly half the size of the "40-foot" letters, and so on.

Make sense?

Of course, if you're nearsighted, the closer you bring the chart, the better your vision will compute out to be. That's why the chart is supposed to be used at the furthest distance practicable when measuring your distance acuity. Eye doctors like to say that 20 feet is optically equivalent to infinity. Actually, for perfect focusing, you must make a change of 0.16 diopters when going from 20 feet to infinity. This means that you could be 0.16 diopters nearsighted and still test 20/20, or even 20/15! But your vision for stars would be less than optimal.

By the way....

I deduced this all one day by measuring the letters on my eye chart. It may turn out, however, that these calculations are only approximate. Perhaps someone with a better knowledge of geometrical optics could give us the real formula.

Due to the high volume of the past week or two, and the mass unsubscribing that ensued, I am going to be moderating I_SEE for the next week or so. What this will do mostly is just slow down the list. I will be stopping messages of an administrative nature (i.e. "please stop sending me email"), and with those that I feel violate netiquite, I will bounce the message back to you, and let you re-edit it. If you disagree with me the second time, I'll let you have it your way. I also may answer a question posted with my answer, instead of having one post for the question and one post for my answer. This will also cut down on volume. Of course, this means I always get the first word if I want it.

Fair? Unfair?

Hey, who said this list was supposed to be fair?

Don't worry, I won't try to squash debate or "dangerous ideas".

 - *Date:* Sun, 21 Jan 1996 14:01:58 -0800 (PST)
-

To measure 20/20 vision at 10 feet, use the 20/10 line on the Snellen chart. At 20 feet, a 20/20 Snellen "E", is 8.73 mm high and subtends 5 minutes of arc vertically. "E" is composed of two gaps and three strokes, each of which subtends one minute of arc, which is theoretically the smallest easily resolved retinal image size based on anatomy. (Three cones in the fovea will "see" this 1 minute image. Because of diffraction effects at the retina, one cone alone cannot usually resolve an image).

Many people of course can do better than this, ie, 20/15 or even 20/10 acuity.

Each minute of arc is then $8.73/5 = 1.746$ mm at 20 feet. At 10 feet, the "E" only has to be 1/2 of 8.73 or 4.37mm. That is what I actually do at screenings where the room is an odd length- proportion out the length of the room; a 10 foot room would be 10/20 times 8.73= 4.37. I then find letters that size and they can be used for a 20/20 target

So all you have to do is use a proportion to figure out what acuity you are measuring if the room is not 20 feet long. 20 feet is the standard length because it is close to optical infinity (but not quite) ie, the normal eye does not have to focus at all to see at that distance.

I wonder if others have experienced what appears to be a phenomenon of "internal vision"?

Certain conditions seem to be necessary: a deep sleep that is interrupted by some noise or disturbance but not enough to wake one fully. While in that twilight state, I have 'seen' what seems to be a wonderfully illuminated transparency sometimes of multiple prisms that shift in rhythmic patterns or, more recently, a multi-coloured image that contained richly saturated patterns and designs.

I recall an article in the NYTimes from years past that alluded to this phenomenon but don't remember whether it guessed at what it represents.

Can someone offer insight[s]?

TIA,
Vincent

I most often see them when
my blood is really pumping and
the light is from about 45 degrees (i.e. mornings, afternoons)
I am not consciously focusing on anything

The most recent occassion was while jumping on the trampoline in the
backyard with the kids. I, too, see them with my eyes closed, and believe
them to be blood cells carrying oxygen though some part of my eyes. Mine
seem to be following the same little paths, one after the other - if I
watch for a while, I can see where the trails are.

Another time I saw them while daydreaming in the car, my focus entirely
relaxed, nothing logical going on.

It is probably possible to see them in the dark; I don't usually do much
aerobic excercise at night <G>. Or at high noon, for that matter.

Greetings!

I received a coupon in the mail for a local optometrist (Austin, Texas) who would like to examine people for \$29.00. I'm thinking of taking advantage of the offer to see what my vision rating is right now. Also, I will probably need some undercorrected lenses for driving and working in front of a computer.

I have seen several notes in the past suggesting that there is no need to correct for astigmatism. Some of the comments that I have read in Dr. Kaplan's book (I'm only in the first chapter) suggest that astigmatism is too variable to validly correct for with glasses. Is it a general rule that someone bent on vision improvement should avoid correction for astigmatism, or are there some special circumstances?

Mark

There is a review of PRIO glasses in PC WORLD, Feb 1996, page 334.
"New Sight for Sore Eyes" by Steve Bass

Some quotes from the article:

"The difference was like night and day. I've been using the glasses for 30 days now, and I'm stunned at how much better I can see the monitor. Images are sharper than they've ever been, my eyes don't get tired, and, well, it just feels easier to settle in on the screen."

Dr. Jonathan Gording says, "The problem is that the computer is behaving to the eyes as if it's 8 or 9 inches closer than it really is. If you're 22 inches away, it's like being 13 inches from the screen."

"The PRIO glasses' prescription compensates for this visual discrepancy, bringing the focus of your eyes up to the plane of the monitor."

"Eschewing the traditional eye chart, PRIO uses a gizmo that simulates a small color computer screen, positioned the same length from your eyes as is your monitor at home."

"...They're great reading glasses. However, PRIO glasses blur everything more than a few feet away..."

"...a PRIO test shouldn't cost more than about \$80. Figure another \$75 to \$200 for the glasses..."

PRIO Corp.; 800/621-1098, 503/636-3707

This is all I know. I just wanted to bring it up for discussion and

present the information to help anyone on the i_see list.

Yes, you can, we all can, if we take the time to notice them.

There's no big revelation here. If you close your eyelids and press on them (lightly) for a while, you will see spinning, swirling patterns and lights (this is not extremely healthy for your eyes, BTW).

I wondered why this was, so I prompted this question on USENET several months ago. The response I got was from a physician to said that the neurotransmitters in your eyes, along with being senseitive to light, are also sensitive to pressure, and putting pressure on them will cause them to fire signals to the optic nerve, thus resulting in you "seeing pressure", which manifests itself in a variety of forms, including tiny white things (whew!).

So why do you see things even when you're not pushing on your eyes? Because there's always pressure on them, usually coming from the blood vessels. That explains why being stressed out causes you to see things, and migraine headache sufferers offen report seeing silvery white flashes.

I hope this clears things up.

-Stephen.

Snellen Chart

- *Subject:* Snellen Chart
 - *From:* "Herbert T. Black" <blackht@pacificu.edu>
 - *Date:* Tue, 23 Jan 1996 11:15:59 -0800 (PST)
-

To measure 20/20 vision at 10 feet, use the 20/10 line on the Snellen chart. At 20 feet, a 20/20 Snellen "E", is 8.73 mm high and subtends 5 minutes of arc vertically. "E" is composed of two gaps and three strokes, each of which subtends one minute of arc, which is theoretically the smallest easily resolved retinal image size based on anatomy. (Three cones in the fovea will "see" this 1 minute image. Because of diffraction effects at the retina, one cone alone cannot usually resolve an image).

Many people of course can do better than this, ie, 20/15 or even 20/10 acuity. Each minute of arc is then $8.73/5 = 1.746$ mm at 20 feet. At 10 feet, the "E" only has to be 1/2 of 8.73 or 4.37mm. That is what I actually do at screenings where the room is an odd length- proportion out the length of the room; a 10 foot room would be 10/20 times 8.73= 4.37. I then find letters that size and they can be used for a 20/20 target

So all you have to do is use a proportion to figure out what acuity you are measuring if the room is not 20 feet long. 20 feet is the standard length because it is close to optical infinity (but not quite) ie, the normal eye does not have to focus at all to see at that distance.

You can't put physical pressure on neurotransmitters, or else my mind is running out of its norepinephrine and dopamine and can't think clearly, in addition to running out of taurine and glutathione and messing up my ability to see clearly.

Astigmatism that is typically measured during optometric tests are composed of two elements. The first is the structural amount which shows up on the cornea and the refraction. Very often there are other amounts of astigmatism which are more functional in nature. In my research i have found that it is unwise to have the functional astigmatism precribed and worn befor the eyes. In my own case, I have nearly 1.00 dioptres of astigmatism and through my vision training program, I am noticing that I can vary my astigmatic perceptions by how I program my eyes to look, how I think and feel about myself, and my moment to moment view of life. I f you have been wearing a lens prescription for astigmatism, I have found it unwise to eliminate the astigmatism component during the first reduction in myopic power. If the astigmatism is under 1.00 dioptre, then you can consider halving the astigmatism if it has been worn before. This reason for these suggestions would require a lot of explanation, which if the group is interested I could get into. This is where I make a distinction between transitional, vision fitness and therapeutic lens prescriptions.

Trust this makes this point clearer,

```

```
>At 10 feet, the "E" only has to be 1/2 of 8.73 or 4.37mm.
```

Herb, I have a nit to pick with this, even though I agree that the calculations are correct. It's a matter of semantics more than optics, but I think it's important.

I say it is incorrect to say that what you are measuring at 10 feet is "20/20 vision". You should say you are measuring "acuity at 10 feet." 20/20 means, by definition, that you can read at 20 feet (first 20) the smallest eye chart letters the normal eye reads at 20 feet (second 20). Furthermore, we should not say "20/20" line or "20/10" line. It is a 20 line or a 10 line, period. At 10 feet, you use the 10 line as a standard for normal vision, and at 20 feet you use the 20 line for normal vision. At 10 feet, if the smallest line you can read is the 20 line, it means your acuity is "10/20" or "half normal at 10 feet". If you can read the 10 line, your acuity is "10/10" or "100% normal at 10 feet."

True, the 8.73mm letter viewed at 20 feet projects to the same size on the retina as the 4.37mm letter viewed at 10 feet. But, when diagnosing near-sightedness, the question isn't "how small can you see" (acuity) but "how small can you see things AT A (given) DISTANCE?"

You could be as much as a third of a diopter myopic and see clearly the 10 line at 10 feet, whereas in order to see the 20 line clearly at 20 feet, you have to be less than a sixth of a diopter myopic.

In all fairness to Herb, if you can see normally at 10 feet, it's likely you can see normally at 20 feet too -- changing focus from 10 to 20 feet

is a difference of only a sixth of a diopter. Glasses for less than a half a diopter of myopia are rarely prescribed.

Incidentally, the closer you get, the more diopters you need per unit distance. Example: to switch from 1 meter to 25cm (distance = 75cm) requires an increase of 2 diopters, while a switch from 1 meter to 4 meters (distance = 3m) requires a decrease by the same amount -- two diopters. Double the distance, halve the necessary diopters. So the further away you get, the less difference it makes. Photographers are familiar with this phenomenon. For close ups, you have to be more careful about focusing than for distant shots (right, photographers?)

--Alex

Getting it

- *Subject:* Getting it
 - *From:* solusrex@soho.ios.com
 - *Date:* Wed, 24 Jan 1996 21:30:48 -0500
-

I finally saw i_see home page. Anyone not afflicted with PCphobia will find it amazingly stupid, but all this time that I've been trying unsuccessfully to get there I was simply using an erroneous location line (two letters transposed), yet was fast to attribute lack of success to my general lack of user proficiency. (I never really learned how to use a PC in an intelligent way -- I just happen to be married to a sys.admin., so my modus operandi is monkey see, monkey do.) Anyway, I'm getting better, although much of computer-related stuff just keeps bouncing back from wherever it is in my cortex that I'm trying to designate a storage area.

Now to the point. I read Richard McCollim's article and unexpectedly found a clue to yet another mystery that my eyes have presented me with. Here's a relevant quotation:

"Suzuki performed an experiment in which he injected radiopaque material into the vitreous of a cat's eye, which during accommodation moved in a direction indicating that the vitreous was forced against the back of the lens and also somewhat toward the posterior pole of the lens." (11)

An experiment by Koke produced a similar result. He injected cat eyes with radiopaque material and took X-rays during miosis and mydriasis, which showed that during accommodation the vitreous moved toward the lens and inward toward the optic axis. (12)"

Eureka! I immediately realized that I'm one of those hapless lab cats, with floaters instead of the radiopaque goo swimming in my vitreous, hardly detectable from the outside but perfectly traceable from within. I have two particularly large and annoying ones. The one in the right eye looks like one of those astrological maps of constellations where the stars are connected with lines forming a particular figure. And I'm not into astrology. In the left eye, I have a very precise replica of a crucifix, with the little Jesus holding a long scarf in his hand (his own loincloth?) and waving it about. And I'm not even Christian. Very annoying, and I've often wondered why a more pious person than myself wasn't blessed with these

images in her vision field. She might have interpreted them as the sign of being chosen or something...

Anyway, I noticed that these floaters change their pattern of movement when my vision clears up. In a blur, they move from side to side; in a clear flash, they move back and forth, and the more pronounced this movement, the clearer my vision. I've learned to accommodate by just locating and tracing them, and voluntarily moving my eyeballs sort of inward (subjectively it's "inward," although not to an extent where I would be able to see it in the mirror.) So my guess is, understanding myopia MUST include understanding the behavior of the vitreous.

In addition, I found that I can only see the constellation floater when my both eyes work as a team; otherwise I see a lot more of the crucifix. That's because I have contra-lateral dominance, i.e. I'm emphatically right-handed but my dominant eye is my left one. Although my vision acuity is about the same in both eyes, my left one tend to focus faster; I favor it for taking aim when shooting (not that I'm able to hit anything yet, at least nothing I intend to), and in tennis my favorite ball always approaches me from the left. Some of the greatest baseball players also have contra-lateral dominance, so it's no big deal in itself, but I see a lot better when my eyes focus together, not one by one. So now I just focus on the constellation when I want to remind my right eye of its duties.

The most important recent events in my vision have to do with an extensive research I've undertaken in the past 3 months, in a desperate attempt to turn this vast and deep ignoramus into a sudden neuroscientist. The endeavor resulted in a series of practical experiments on my very own neurochemical organization, involving brain amines, precursors to neurotransmitters and neural hormones, and nootropics (Europeans among you might know what I'm talking about -- the latter is a whole class of pharmaceuticals widely used in Europe and involved in enhancing memory and overall nonverbal intelligence). Well -- about a week ago, I started getting my first results. My clear flashes are very stable now -- in fact, I can maintain them indefinitely in many situations, interrupted by only short flashes of blur. My floaters are paler and smaller and look like they're wasting away rapidly, poor things. My monocular polyopia in the left eye is all but gone, and in the right eye, is reduced to dyplopia (a significant achievement for someone accustomed to seeing sixteen moons arranged in the sky in no particular order). My unaided vision is now fully functional -- it's a world of objects consisting of details consisting of more details, with faces, street signs, all the basic necessities. (Just to remind you -- with -8D and pronounced astigmatism, removing my glasses used to mean living among faceless blobs of human presence, uniform rivers of mysterious light instead of the oncoming traffic at night, things like that.)

An unexpected side effect: if I only could afford it I would now seek formal education in neuroscience, in addition to visual re-education. Well

-- for now I'll just have to add another dream to my looong list...

Stay clear and cool.

Elena

Know thyself. (Socrates)

OOps!

Dennis Yelle kindly pointed out a goof-up in my last post...

On Wed, 24 Jan 1996, Alex Eulenberg wrote:

>
> Incidentally, the closer you get, the more diopters you need per unit
> distance.

This is still true, but the example and the formulation was incorrect!!!

Here's what I believe to be a correct example (not Dennis's): Since a diopter is the reciprocal of the distance in meters away from the focal point (i.e. your retina)...

0.50m away	=	1/2 m	=	2/1 diopters	=	2.00 D
0.66m away	=	2/3 m	=	3/2 diopters	=	1.50 D
1.00m away	=	1/1 m	=	1/1 diopters	=	1.00 D
1.50m away	=	3/2 m	=	2/3 diopters	=	0.66 D
2.00m away	=	2/1 m	=	1/2 diopters	=	0.50 D
infinity	=	1/0 m	=	0/1 diopters	=	0.00 D

So we see, in terms of diopters, the difference between 50 cm and 66 cm is the same as the difference between 1 m and 2 m, which is the same as the distance between 2 m and infinity!

To pull your focus inward from 1 m to 0.5 m requires an entire diopter, while to push your focus outward from 1 m to 1.50m requires only 2/3 of a diopter!

Also, it follows, if you have 0.0 D of myopia you can see infinitely far away! With 0.5 D of myopia, you can see clearly up to 2 m away; if you have 1 D, you can see clearly up to 1 m, etc...

Notice that if you have myopia, you want to "subtract" the number of "extra diopters" you have in your eye. This is why myopes are prescribed lenses with "minus" diopters.

Did I get it right this time, optics wizards?

So, for those of us high myopes:

0.25m away = 1/4 m = 4/1 diopters = 4.00 D
0.20m away = 1/5 m = 5/1 diopters = 5.00 D
0.17m away = 1/6 m = 6/1 diopters = 6.00 D
0.14m away = 1/7 m = 7/1 diopters = 7.00 D

This is the clearest explanation I have heard (seen). I hope this is it, because it answers some questions I have had. . . . Seems it might be easy to overcorrect, as the numbers get higher. . .

Alex;

I guess this is really only a matter of semantics. You are technically correct to call acuity 10/10 if a person can read the 10 line of a standard Snellen chart at 10 feet. However, when I go on a Lions Club screening, for example, where there is only 10 feet of space in the trailer, they have

Howdy all. I have a question about whether anyone know if the soft, very fine grain bean-type bags are good for your eyes' relaxation as they do touch the eyeball when you use them . The presure is quite heavenly & relaxing.

Also, about the "body breathing" mentioned in a message about personal VT techniques a while ago, it's not bad per se to be yawning like crazy as you mentioned, yawning is our body's natural response to not getting enough oxygen (I think more precisely it's a too-high CO2 concentration), so your body's just making sure your cells don't asphyxiate. Better, I think, is to breathe pretending that the air coming in & going out is a deep fog & fill your lungs from the belly up & empty from the throat down.

Also, in my Aikido class we "palmed" & I asked the sensei & he said it was an Aikido exercise. I guess that's some sort of proof that palming does something. Personally I thing it teaches your eyes to relax and then once relaxed, they can function properly again. Just like in hata yoga the idea is to really exert your muscles for a short period of time and then relax them completely, coupled with a stretching out of the muscles, so too does sunning exert the eye muscles, palming relax them & other VT exercises like swinging stretch the eye muscle out. I hope I'll see the same results that I have in hata yoga!

Deep breathing also helps relaxation & infuses Oxygen to help tired eyes. Here is a breathing exercise instruction I downloaded:

Pranayama Instruction

Ceci Henningsson (ceci@lysator.liu.se) 11 Oct 1994 writes:

(Updated: October 11th, 1994)

PRANAYAMA IN THREE EASY STEPS

This is my experience from learning Yoga breathing and pranayama using the book "Yoga -- en praktisk vaegledning" (Yoga -- a practical guide) by Swami Nirvikalpananda Saraswati for instruction. This article is meant to help you teach yourself the technique. It is not meant to be authoritative with regards to definitions or Yoga theory.

Pranayama is a breathing practice in Yoga. It is particularly useful in situations where you feel threatened, because it helps you retain your calm. Pranayama is often recommended to the beginning occultist. Among authors who recommend it are Robert Anton Wilson and Aleister Crowley.

Preparation

Wear loose-fitting clothes or no clothes at all. Make sure your nose is clear, so you can breathe freely. If you have a cold, you will have to wait till you are recovered. Not only is it impossible to do pranayama when you cannot breathe through your nose but if you have a sore throat the first deep breath will send you into a violent cough attack.

Step One

The purpose of the first step is to learn to distinguish between belly breathing and chest breathing.

Lie on your back on a comfortable flat surface. Relax and start following your breath. Put one hand on your belly and the other on your chest. Relax.

Belly breathing: When you inhale, the hand on your belly rises, while the hand on your chest remains still. As you exhale, the hand on your belly goes down again, whereas the hand on your chest remains still. Repeat this for 5-10 breaths.

Chest breathing: When you inhale, the hand on your chest rises, while the hand on your belly remains still. As you exhale, the hand on your chest goes down again, whereas the hand on your belly remains still. Repeat this for 5-10 breaths.

Alternate between belly and chest breathing for 5-10 minutes. Repeat every day. It is vital that you master this step before going on to step 2.

Step two

Purpose of step two is to combine belly and chest breathing in one breath. This is called Yoga breathing.

Lie on a comfortable flat surface. Relax and follow your breath. Put one hand on your belly and the other on your chest. Relax.

Yoga breathing: Start inhaling with belly breathing. When you feel that you cannot inhale any more this way, go over to chest breathing until the chest part of your lungs are full. Then you exhale using chest breathing first and then belly breathing until you have emptied your lungs completely.

Breathe very slowly. If you feel dizzy, you are breathing too fast. If you feel out of breath, you are breathing too slowly. Follow your body's signals.

If you have problems distinguishing between belly and chest breathing, go back to step one again.

Step three

Sit or stand with your spine upright.

Use Yoga breathing and follow a set pattern. To do this you need to somehow count the rythm. I use ordinary counting, but I imagine that you might aswell use words instead. The rythm 4-2-2 works very well for me. That means I count to 4 while inhaling, hold my breath while counting 1 and 2, and exhale on 3 and 4. I have also seen a 4-4-4-4 rythm recommended and now find it more efficient. It means adding an extra element, namely holding your breath between exhalation and inhalation. Be careful not to hold your breath for too long. Again, listen to your body's needs.

Yoga breathing should be a more or less effortless process, so your breath should not be louder than usual. I had problems with starting the exhalation inaudibly. If you experience this too, there is a trick to it: you inhale just a wee bit before exhaling. You are supposed to be able to use pranayama in virtually any situation, so to practise making it an "invisible" process is definitely worthwhile. That way you can use it, for instance when you walk up to the platform before making a speech or when listening to someone in an argument.

I also had problems with my diaphragm going rigid. When this happens I can make it relax through softly patting on the diaphragm. The stimulation seems to confuse the muscles on the inside into relaxing. It did not happen any more when I got more used to the practice.

Practice

It is a good idea to practise step one for a week, then combine step one and step two for one week, and then try all three steps in your daily session during the third week. This way you repeat the first basic steps every time. I followed this advice and feel that I have learnt the basics quite well. I still feel the need to practise distinguishing between belly and chest breathing from time to time. Pranayama works better if you practise it regularly. Do not do it all the time, but a few times a day

will not hurt, quite on the contrary. My Yoga book recommends doing pranayama before meditation, but after asanas.

(Note: this article was cross-posted to sci.med.vision, under the heading "Re: Glasses or no glasses ???")

In article <4e6rau\$qmg@shellx.best.com>,
>Good thoughts to ponder... of course that's the crux of the matter:
>"What causes myopia"?

>Question: Can you tell me more about these "recent experiments"?

An article appeared in the November 11, 1995 Science News (vol. 148, pp. 318-319) by Lisa Seachrist called "Growing In and Out of Focus: The eye adapts to avoid blurry images". Mention is made in that article of research by Earl L. Smith at the University of Huston School of Optometry. His research team put goggles on the monkeys, where one eye got a plus or a minus lens, and the other eye got a non-refracting lens. The monkeys wore the glasses for 12 weeks. "The eye with the refractive lens either grew or stopped growing until the animal could see clearly with it. In the ensuing year without the goggles, the animals' eyes slowly grew to compensate for the lack of lenses until the eyes became balanced again." writes Seachrist.

Many similar experiments have been done on various animals, including chicks and shrews. I see no reason why humans should be an exception. For the collection of experiments done on monkeys -- both young and adult, see my "myopia control" bibliography, at

http://silver.ucs.indiana.edu/~aeulenbe/i_see.html

>Another question: Do you think muscular act of focussing (ciliary body >action) causes structural changes in the eye? What kind of changes? >in axial length?

I believe that the muscles in and around the eye are capable of affecting the cornea and causing the eyeball to elongate. Under what conditions -- in terms of kind of focusing demands, diet, state of the digestive system, state of the circulatory system, state of the nervous system -- within what time scale, and to what extent, I can't say.

The following I do know (time for my trademark ancient article citations!!)

Two hundred years ago, experiments were published in the Philosophical Transactions of the Royal Society of London, wherein corneal changes were observed during accommodation. The corneal changes alone were not enough to account for accommodation, and the experimenters believed that the cornea, lens, and vitreous chamber all were involved in the act of accommodation.

I have retyped these articles and have made them available at

http://silver.ucs.indiana.edu/~aeulenbe/i_see.html

under the "I_SEE library" -- Works on the Mechanics of Vision.

Dr. Fukala of Pilsen-Karlsbad wrote in 1890:

:I operated two years ago on a boy, aet. 16 years, (both eyes) for
:zonular cataract. he now reads with correcting glasses -- + 10 D --
:Jaeger No. 2. Although these observations, first published by Forster,
:were, as is well known, denied by Donders, Woinow immediately after, by
:means of his careful experiments, proved undoubtedly that people with
:aphakia really possess a not unimportant amount of accommodative power"
:('Treatment of Myopia by Removal of the Lens', trans. by C. A. Wood,
:American J. of Ophthalmology 11, 357-360).

In 1895, Dr. A. Edward Davis of the Manhattan Eye and Ear Clinic reported several cases of accommodation in the lensless eye. One lensless subject, with the same pair of glasses, had 20/10 distance acuity and was also able to read fine print (Jaeger 1) from 8 to 22-1/2 inches. It was observed that when he focused, his cornea moved forward and there were other, optical, evidences of change in refraction. The same changes took place "when the lids were held open with a speculum, and even when the ciliary muscle was paralyzed with scopolamine." The author concludes: "The changes produced in his cornea must, therefore, have been produced by the action of the external muscles of the eye." His article in the reports of the clinic for that year, "Accommodation in the Lensless Eye -- To What is it Due" cites several other similar cases and experiments.

Jesse S. Wyler in the /Ophthalmic Record/ of 1909 writes that "a pseudo-accommodation which may be the result of the pressure of the converging muscles upon the bulb" often allows a myope whose lens has been removed "to dispense entirely with glasses for close work"

William Bates -- dare I mention his name -- published an article in the New York Medical Journal in 1918 describing changes in the curvature of the cornea and sclera during accommodation, with the direction of gaze held constant, as evidenced by reflected light.

Especially after Fincham's experiments showing how the lens changes during accommodation, there has been little effort to measure the changes in the cornea or sclera -- however slight they may be -- that might occur during accommodation. Nor do most modern myopia researchers ever give such mechanical considerations any thought. The buzzword now seems to be "retinal growth factors"

However, Jim Day, OD, of Alabama <JimDayOD@aol.com> has reported just this past year, that slight corneal changes in the direction of myopia occur under the influence of miotics (drugs that force contraction of the pupil and -- in the proper proportions -- close focusing). Email him for complete references.

> Could this explain why most hyperopic children eventually
>become emmetropic at some point in their life?

I believe so.

Many apologies about the delay in responding but I only go on the net occasionally.

"hypermtropia, acquired Hypermetropia resulting from changes in the refractive indices of the media due to either age, or to surgery"
- Dictionary of Optometry 3rd ed Michel Millodot, Butterworths

If you want studies to back up known shifts in refractive conditions with age or other factors I found a heap of studies summarised in :

Clinical Refraction Vol 1 p14 - ??? 3rd ed Proffessional Press

Borish

In your last paragraph that iI have quoted you have wrongly stated the current thinking on refractive conditions. Who told you that things were fixed ?

I also deny telling you that you would become longsighted. I only said that I would have expected a shift in that direction at around this time.

I hope this helps.

Peter Locher

(originally posted to sci.med.vision under "Re: Cause for Myopia ?")

Deciding to argue against a behavioral optometrist for a change!

On sci.med.vision, in article <4ehelt\$p32@ixnews6.ix.netcom.com>, Paul Harris <babo@ix.netcom.com> wrote:

>Myopia is a complex situation with multiple possible causes. It is
>understood that most varieties are triggered by sustained near centered
>activities such as reading and VDT work. The greater the volume of
>close work, the greater the intensity, the more oppositional the
>attitude, the poorer the nutrition, the worse the print, the poorer the
>lighting etc..... you get the idea I hope about the connection. It is
>well established through many papers many of which date back to the
>early part of this century. The physiology is now pretty well
>understood.

Paul, somehow you managed to leave it all at an innuendo: "you get the idea I hope about the connection." What, is it unethical for an optometrist to say explicitly that something is a CAUSE of myopia?

Assuming that that IS what you meant -- that the things you mentioned above cause, or "trigger" as you say, myopia, I think about half of what you said is truly "well established", while the other half is mere speculation, if not completely disproven.

1. Volume of close work
2. Intensity of close work

I suppose by volume you mean "total time spent" and by intensity you mean "how close". I think that these two probably do have the most support in the literature. I think of the latest results from the Orinda myopia study conducted at Berkeley, where a group of schoolchildren have

been followed (and continue to be followed) as to their refraction and ocular dimensions. They included a variable called "diopter hours" which was 3x hours spent reading + 2x hours spent playing "video type games" + 1x hours spent watching TV. Granted this is a very crude variable (it does not take into account time playing piano, time spent doodling during class as opposed to looking at the chalkboard or out the window, etc.). Nevertheless, they found that "diopter hours" correlated with degree of myopia, all other things being equal (the researchers claim to have demonstrated a genetic component to myopia as well). No prospective studies have been done on humans, but plenty have been done on monkeys in support of this idea. "University or academy life" has been found to be associated with development of myopia past the "growing years." This may be due to the close work involved, although it could be for other reasons.

3. Oppositional attitude

This one I must disagree with. I think most people will agree that myopes as a class love close work, are introverted and passive; it's the hyperopes that "oppose" close work, are dyslexic, are therefore "trouble students", etc. Perhaps you meant something else by "oppositional attitude"

4. Poor nutrition

I agree on this one. This one is rarely talked about, but several researchers, working independently have found that low-vitamin or low-protein diets are correlated with myopia. One British (Gardiner) and one Australian (Walkingshaw) reported modest improvements in progressive myopia after instituting a high-protein diet. But since it's hard to find sources of protein that aren't also sources of other nutrients, I wouldn't jump to the conclusion that protein is the key.

5. Poor print

I do not believe any study has established a connection between poor print and myopia. It is a common conception that reading poor print leads to bad eyesight, but who has done anything to prove that it causes myopia?

6. Poor lighting

This is another factoid, that poor lighting causes myopia. I know of three reasons given why poor lighting supposedly causes myopia

- a) it's difficult to read in poor light, and therefore people become myopic as a result of the strain.

This is commonly offered in earlier literature, however one curious fact that William Bates observed (for what it's worth) is that when one

strains to see at the near point in the dark, one actually becomes hyperopic, not myopic. I do not believe anyone else has done any experiments to prove or disprove this statement.

- b) poor lighting reduces acuity and therefore one is tempted (or forced) to bring the text closer in order to make the text more legible. Because of the increase in intensity of the close work, myopia ensues.

This is more reasonable, but then according to this, lighting really isn't the factor, we're back to factor 2, intensity of close work. (Or factor 1, volume of close work -- if the poor acuity slows you down)

- c) exposure of the skin to full-spectrum light is essential for the synthesis of vitamin D, which is used in the absorption of calcium, which is a component of the coats of the eye; too much darkness leads to a calcium deficiency which leads to a weak eye which elongates under the normal intraocular pressure.

This is the only explanation that I will accept as having any sort of experimental basis. Note, however, that "adequate lighting" means much more than a 100-Watt bulb here. It means getting out into the sunshine -- even if your eyes are closed!

7. The physiology is now pretty well understood

If that were true, there would be no controversy. I guess it all depends on who's doing the understanding. I will end with a comment by J.G. Sivak, a prominent myopia researcher from the University of Waterloo (emphasis mine):

"The suggested link between accommodation [close focusing] and myopia is not new, nor did it originate in the optometric literature. Both Donders and Helmholtz [two Ophthalmological giants of the 19th century] believed that excessive accommodation could lead to myopia, and a variety of mechanisms, including accommodative increases in intraocular pressure and permanent accommodative lenticular change, have been suggested. However, suggested mechanisms, of whatever type, must be considered with some skepticism when THE OVERALL MECHANISM OF HUMAN ACCOMMODATION ITSELF IS STILL NOT COMPLETELY UNDERSTOOD AND QUESTIONS SUCH AS THE SIZE AND IMPORTANCE OF NEGATIVE ACCOMODATION ARE STILL UNCLEAR."

--Alex

PS for a more in-depth look at the theories of myopia causation (with references), see my paper at

http://silver.ucs.indiana.edu/~aeulenbe/i_see.html

on the preventability of myopia.

Re: Causes of Myopia

- *Subject:* Re: Causes of Myopia
 - *From:* Beyond 20/20 Vision <Beyond_20/20@Sunshine.net>
 - *Date:* Tue, 30 Jan 96 14:35 PST
-

>PS for a more in-depth look at the theories of myopia causation (with
>references),

I am surprised that very little discussion is devoted to the psychoemotional causes. In my book *The Power Behind Your Eyes*, I hypothesize that Myopia, as in most physical deviations seen in the eyes, are initiated by our thoughts triggered off by some inability to cope with the world. This can be predisposed from genetics and also from life situations and challenges. I would like to see more discussion devoted to perhaps the real causes of the physical manifestation of Myopia. I thank you Elena for your consistent reminders of this important link.

Robert-Michael Kaplan.

mental seeing exercise

- *Subject:* mental seeing exercise
 - *From:* michael c brady <mbrady@indiana.edu>
 - *Date:* Tue, 30 Jan 1996 13:57:15 -0500 (EST)
-

I apologize. I have good vision. But I came up with an "exercise" that might be of some use to people. I'm more interested in problems of perception that have to do with higher centers in the brain. That's what this is aimed at.

I assert that when a person is attentive to something, and it seems blurry, (out of focus) there must something in their field of vision that is in focus. It's just that their attention isn't directed towards it. And if their attention is directed towards that which is in focus it becomes out of focus. (They learned how to focus when they were little but their eyes grew unproportionately - leaving eveything out of focus when it originally would have been in focus)

Maybe there is a way of redirecting attention to that which is in focus from that which is unfocused (without changing the shape of the eye). To relearn how to synchronize attention and the eye muscles in other words.

So here is my exercise:

I bought a \$3.00 watch at Target a couple of weeks ago. It has a cover that opens to let me see what time it is. Printed on the cover is one of those magical things where if you tilt it a little bit, the image changes. Mine is a statue/gargoyle that changes into a roaring purple monster. I found that if I hold it close to my face, one eye can see one image while the other eye sees the other image. I noticed that if I really concentrate, I can see one image then mentally shift and see the other image.

This doesn't have much to do with refocusing my eyes except that it lets me direct my attention (and change my perception) without actually changing my visual input or moving any eye muscles.

If I think of a good focusing exercise, I'll let you know..

Last week, Rob Barnett brought up the subject of PRIO glasses. On sci.med.vision today, Larry Bickford, OD, posted the following description of what they are:

```
----- Forwarded message -----  
From: eyecare@west.net (Larry Bickford, O.D.)  
Newsgroups: sci.med.vision  
Subject: Re: Anyone have any experience with PRIO glasses?  
Date: 31 Jan 1996 16:28:37 GMT  
Organization: The EyeCare Connection & CyberLens!
```

In article <4en4v6\$euf@newsbf02.news.aol.com>, krazybob1@aol.com (Krazybob1) wrote:

```
>  
> I am an optomerist, and I recently read about PRIO glasses in a computer  
> publication, but would like to know if anyone out there has any first-hand  
> experience, either as an examiner or a patient.
```

Yes, on both ends. My take on PRIO is that is a marketting scam---albeit one with some valid testing and prescriptive protocols.

The use of their proprietary "computer monitor" simulator is an interesting and effective device to help examin the patient under simulated workstation environments. But one could also take a good history, use some common sense and experience and come up with the same results. A pretty cool device, though. Really impresses the patient, but not me.

The resultant lenses are nearly the same as what you'd expect, usually with .25 or .50 more plus than you might be used to prescribing, with tints and coatings to enhance contrast on various types of screens (amber, color text on color backgrounds, etc) and reduce glare. Nothing really out

of the ordinary.

What is out of the ordinary is their marketing arrangements: In order to be "authorized" to use their vision-tester and to receive "rebate credits", you must order the lenses from a list of their contracted laboratories. Kinda feels like I'm getting my arm twisted.

The bottom line is that they do make it easy to RX computer specs and show off a new toy to your patients. You certainly can (and should) be doing the same without PRIO toys, and I have a problem with their marketing practices. Nothing evil about it, just business. I've chosen not to participate.

Larry

Seeing well through eyelashes

- *Subject:* Seeing well through eyelashes
 - *From:* "George Tohme" <PolySoft@msn.com>
 - *Date:* Thu, 1 Feb 96 11:35:02 UT
-

Hello,

Could someone explain to me how, being a myop (-3.00, -3.75), I can see things extremely sharp by just closing my eyelids (not completely) and looking through my eyelashes. I'm not squinting or exercising any tension on the facial muscles.

This might be related to the fact that wearing pinhole glasses produces the same result but some far I have not heard/seen any explanation to this one either.

many thanks
george

>

Thanks for noticing, Dr. Kaplan!

My hypothesis is, being reluctant to see psychoemotional links is a symptom of myopia in itself. We myopes are all, to varying extents, left-brained freaks of nature -- and the left hemisphere loves straightforward scientific explanations and hates metaphors, especially the self-referential kind. Many of us prefer to rationalize and intellectualize rather than love and hate and search our souls for answers. Long histories of suppressing direct emotional responses are often part of the problem. A typical myope's personality is a volcano with a cork jammed tight into the crater. Which makes us all the more interesting as individuals but does little for our visual health.

In my own "self-inflicted" case study, I could opt for any one of three possible explanations. 1.Genetics: my paternal grandmother had -18.00D. (She read insatiably and looked like a human scanning device, moving her head along the length of each line and occasionally brushing the page with her nose.) 2.Early stress on visual system: I started reading at three. 3.Psychoemotional conflicts: in abundance. So which one should I choose as the major cause? The first two seem sufficiently solid... but only if one doesn't look deeper.

Let's take a closer look at the grandmother version, for instance. Instead of genetics, I find myself faced with a bit of family history. Her husband, my grandfather, was arrested and shot without trial in the course of one of Stalin's "purges." He was a journalist and his crime was mentioning a wrong politician's name in one of his articles. That's what my grandmother was able to learn thirty years later; at the time of the actual events, however, he was just taken away "for a little talk," and disappeared. My grandmother went to the local KGB office to ask why they had arrested her husband, what the charges were against him, and what would happen to him. The answer she received was exactly this: "We didn't arrest anybody; you never had a husband; and, since you have two small sons, make sure they remember that they never had a father -- if you want them to have a mother." I imagine developing -18.00D should be considered an ADEQUATE reaction to this kind of reality. So it wasn't genetics after all... maybe a genetic predisposition to breaking at this particular physical level, as opposed to families where people develop autoimmune or cardiovascular disease or ulcers. Btw, my father, who was only four at that time, had normal vision till quite recently, but his brother, who was almost nine when faced with the imperative to pretend he never had a father, rapidly developed high myopia.

George,

I will give the explanation that my optometrist gave me. Simply, he said, it has to do with optics and related effects of seeing an image through smaller apertures. The smaller the aperture the more defined an image becomes. Like letting less light into your receptors allows for your image to not be blurred by "excess" light. His answer did not totally convince me since I have experienced the same encouraging effect as you mention, by looking through pin holes or "skinting". But I think that as matter of fact, his answer is not without basis. If you look at the way a camera works, the smaller the aperture is (when you take a picture) the better a picture exposes the film for far away images.

Does this explanation sound familiar to anyone else?

Well its been a while since I announced my vision quest in December when step 1 involved the confrontation of my optometrist with the ideas of eyesight healing. I saw him in December and its taking me this long to come to grips with accepting or actually not accepting his negative reaction. Its kind of funny, now that I think about it, that his reponse was such an emotional let down. Simply he said that my vision was too degraded (around -7.5 on both) for any of the "intense" exercises to work or have any effect. He did however said that it was totally up to me if I wanted to persue this quest. I am sad to say that I chicken-out at the time and got me the corresponding prescription on my new glasses instead of getting some that were decreased in strength. Now my courage is regaining strenth and will be taking another shot at these methods. It would be encouraging to hear from people who have actually gotten some if not great improvement in their eyesight by practicing these methods as discussed in the isee group.

Vitamin supplements for better vision

- *Subject:* Vitamin supplements for better vision
- *From:* stefansi@ctrvax.Vanderbilt.Edu (Stefan Ivanov Stefanov)
- *Date:* Fri, 02 Feb 1996 13:03:15 -0600

Can anybody recommend any particular brand of (multi)vitamins that are particularly helpful for combating myopia? Is it possible to find the active substance of bilberries in drugs? I looked at the FAQ, saw explanations of how different vitamins worked, but could not see a list of brands that have been tried and found to work/not work.

I'd appreciate any comments from I_Seers who have tried the diet approach.

Thanks for any replies.

Gentlemen/ladies,

I am originally from North Carolina and went to Chapel Hill (God's country !!!) for most of my pre-professional education. I attended Southern College of Optometry, which, when I was there, was very functional in approach. I have, since graduation, attended many functional meetings with O.E.P. and with various O.E.P. approved meetings with Drs. Slade, Getman, Sherman, Adema, etc..... so I tend to be functional in my approach to the visual system. I feel this approach makes one curious and continually looking for answers. As you can tell, I feel this approach is best for me. During my professional life I have worked with children and adults in vision therapy in and out of the office. I have become very active in sports vision and belong to the AOA Sports Vision Section. I have belonged to the International Academy of Sports Vision for many years, and am President of the Academy at the present time. I authored the Sports Vision Manual (a manual to help practitioners get into the field of sports vision) that I am letting the Academy disseminate. It is being internationally published at the present time. I have done research in sports vision and have developed items for the sports player to use to help their visual performance on the field. I am a member of the National Eye Research Foundation (N.E.R.F.) and am a fellow in the Co-management section. In fact, I am communications director of the section. I am getting involved with orthokeratology, as I feel this is one way to prevent children's myopia from increasing over the years. This technique, combined with functionally prescribed therapies including counter-stress lenses, can be of much help in helping children who have developed myopia to the point where functional approaches alone will not reverse/eliminate the myopia. This can also benefit adults, of course, but the greatest impact will be with the children, I feel. I have recently become involved with PRIO. This computer mimicing M.E.M. does, I feel, have validity. I am doing research with the unit and, so far, it seems to work well. I never accept things on face value, so I am constantly questioning everything, and constantly proving/disproving ideas and things to myself

about everything that can have value in helping the patients I am fortunate to help. What else..... I do not like the way managed care is coming in. Not so much managed care itself, but the push for less and less quality.....and reimbursement schedules that are unrealistic.

That's about all....I am married to the same wonderful and extremely patient and understanding woman for the past 26 years and have two sons that are 18 and 15.

I appreciate being asked to join your group.

Thanks again.

Paul Planer, O.D.

hello Mario,

In response to your recent posting, i did have good results when i began my own vision quest about 4 years ago. I was able to improve my prescription from -7.5 / -6.75 to -5.5 in both eyes. This first step took me about a month. Since then i have not had much progress in spite of occassional bursts of physical effort, and continous emotional work.

I keep trying because very near the beginning, i had a flash of perfect vision that was literally breath taking. The clarity and depth of field was very exciting. I thought to myself -- oh my God! Is this what the world looks like? My next thought was something like -- i don't deserve this . . ., and my normal dull, flat, fuzzy vision returned.

If you are persistent, you can and will get results, possibly very quickly, by learning to pay attention to the way you see and changing some things. I personally believe that the emotional issues take longer to uncover and solve. I also believe that is the whole point of living, to have my own vision of my life and not the one i was frightened into having.

I can tell you that my own quest for vision has led me into some curious corners. At the moment, i am about to produce and direct a play that i have written on the subject of domestic violence. It's all on a very amateur level, but i am very afraid of the exposure. Still, i want to do it. It's all falling into place so neatly, i am sure that it's the right thing to do. I feel like i am going through adolescence again. I have been walking about for the past few days with a nest of snakes living in my stomach. The difference is, this time, i intend to acknowledge my fears, and

express them. And do the play in spite of my fear, or maybe, because of it.

All the best to you, and good luck on your journey.

Linda Lee
Vancouver Island, Canada

Thanks for all the replies to my question.

I sort of expected that answer and I should have known that since I do a lot of photography. I guess I was amazed by being able to see so clearly that I hoped there was something (i.e. exercise) that could be done based on that observation to improve my vision.

thanks again

Torres,

Well I guess I was a bit luckier. I saw my optometrist last month, I told him about vision therapy and I gave him a bunch of documents that I picked up from ISEE's home page.

He agreed to go along with it and performed an incredibly thorough test, prescribed weaker glasses, and we agreed that I will see him once a month to see how I am going. He also asked me to document the kind of exercises I was going, how often, how long...

Currently I'm at L:-3.00, R:-3.75

I will continue with my exercises and tests for 6 months. If I do not see any substantial improvement (i.e. at least 0.75 to 1.00) then I would quit. I would continue taking care of my eyes but not with VT as a goal.

I must admit that sine I started my VT almost 3 weeks ago I only wear my glasses when it is absolutely necessary which is about 1/3 of the prevoius wearing time. I do not use my sunglasses at all (which was impossible for me to do) and I seem to be coping fine.

Forget about you optometrist. Either find another one or tell him what you want to do. Make this your own project and control how it's progressing. (enough preaching!!)

I will post the result of my test to let the whole group know how I'm doing.

You are right in your last paragraph, By reducing your palpebral
apertured (or distance between upoper and lower eyelids) you are reducing
the effective pupil size, increasing the depth of focus (the same as
reducing the aperture on a camera) and reducing the size of the blur
circle on the retina. That is why you see more clearly.

You may be interested to know that there is a clinical device called a
stenopaic slit - much like a pin hole effect - using a test lens with a
slit and not a pinhole.

Raymond A. Chamberlin <raych@sirius.com> wrote:
>Does excessive reading cause myopia in monkeys?

>From Young, Francis A. "Primate Myopia", in American Journal of Optometry
and Physiological Optics 58 (1981), 561-566:

:While it is not possible for monkeys to read, in the early studies we
:attempted to reproduce the human reading situation as closely as
:possible. For this reason, restraining chairs were constructed which
:permitted holding the monkeys in an upright seated position which
:approximates not only the human reading position but also the normal
:monkey sleeping position. To duplicate the human reading situation, we
:enclosed the monkeys in a translucent, but not transparent, hood which
:restricted the minimum visual distance to approximately 14 in., and the
:maximum visual distance to 20 in. The visual stimuli included the inside
:surface of the hood, chair parts, food, the watering device, and the
:body of the monkey, especially the hands.

:When fully adult monkeys (one even gave birth in the chair) were
:enclosed in the hooded situation, 7 of 10 developed myopia or changes
:toward myopia which averaged 0.75D in the period of 1 year. While this
:amount is not spectacular, it does exceed the usual amount of myopia of
:approximately 0.5D developed in children over the same period. The
:calculations of the amount of myopia developed included those subjects
:who did not change into myopia whereas in most human situations we
:exclude the subjects not changing and deal only with subjects who are
:changing into myopia. If the nonchanging subjects are excluded, the
:amount of myopia developed is approximately 1.25D of myopia in 1 year.
:Human subjects of a comparable age (18 to 23 years), such as

:submariners, cadets at Virginia Military Institute, or at the U.S. Naval
:academy tend to change at the rate of approximately 0.25D a year into
:myopia. There have been no controlled studies, but heavy readers appear
:to be progressing into the third decade. Thus, it was apparent that we
:could create in most of our animals an amount of myopia which equalled
:or exceeded that found in human populations of younger or comparable age
:levels. [p. 561]

Young, F.A. 1961. The effect of restricted visual space on the primate eye.
Amerian Journal of Ophthalmology 52, 799-806.

>What does inadequate reading cause in optometrists?

Earl L. Smith of the University of Houston College of optometry is
quoted as saying In Science News (11 Nov 1995, p. 319) "these
experiments have all been done on infant animals, and we don't know if
or how the compensation mechanism works in older children or adults."
Recall that Smith is the researcher who put myopic glasses on monkeys
and found that the eyes that wore minus lenses (which forced the
monkey's eyes to focus for near) grew myopic, and whose results were
published in August 1995 Nature Medicine. Apparently he did not know
that Young had produced myopia through distance deprivation in fully
adult monkeys.

Incidentally, Young did perform experiments on young monkeys too. Those
the equivalent of 5- to 6- year-olds "could develop up to 2 to 3 D of
myopia in 1 year in the enclosed visual space condition". By the way,
there are 3 monkey years in 1 human year.

Young. Francis A. 1963. The effect of restricted visual space on the
refractive error of the young monkey eye. Investigative Ophthalmology 2,
571-577.

Hello,

I am a third year Optometry student at Pacific University. I would like to respond to Mario Torres' message regarding eye exercises and his -7.50 refractive condition.

I think your Optometrist was probably referring to the fact that, in the visual sciences literature, studies show that for myopic conditions of 6 diopters or more, structural changes in the eyeball are likely to have taken place, making at least a significant part of this condition irreversible.

Those changes seem to be associated with the axial elongation of the eyeball, that is, the pathway of the light to the retina is now longer. Even if an individual attempts exercises to ameliorate his/her refractive condition and meets success in that attempt, blur is still likely to occur.

To explain this briefly, a sharp image depends on light rays coming into focus at the site of the retina. Even if by eye exercises the light rays were made to come to focus "where they should" had the elongation not occurred, the fact that the retina is not there anymore but further back makes it so that blur is still experienced, as your Optometrist indicated.

If your goal is to see a sharp image without the help of spectacles or contact lenses, it is unlikely that this will occur because if your visual behavior has given rise to a structural change in the eyeball. However, eye exercises may decrease the amount of refractive deviation and stop or slow its progression. Furthermore, I believe eye exercises in the form of a vision therapy program are still helpful for other reasons. Seeing clear is not all that matters in good visual performance. Good visual performance has to do with effortless clear, single vision. Just as much as energy may be spent in the effort of seeing single - keeping the images relayed by both eyes together - as it is in the effort of seeing clear.

For example, people who spend a greater than reasonable amount of

energy in maintaining single vision may experience, after prolonged visual effort, that the images "want to go double if you let your eyes go". Others may never see double because one of the images is being ignored by the brain (suppression) or they may avoid the discomfort-causing visual effort so that these symptoms are never experienced. However, the effort is still there, and the literature indicates that this effort takes away from the ability to concentrate on the task at hand and appropriately absorb the information (for example, as in reading or studying), reducing efficiency.

There is an interaction between your accommodative system (seeing clear) and your vergence system (seeing single). Within this interaction, a refractive condition such as your 7.50 diopters of myopia may progress to worse stages. As the demands on our visual system became more and more complex, Skeffington, and other behavioral optometrists in the post-war era, started to look at dysfunctional visual behavior syndromes as a logical succession of stages that are predictable in their progression as well as in their reversal. According to an individual's specific stage, the system to work on prioritarily may be at times accommodation and at other times vergence. The exercises to be emphasized, their order and timing, etc, as well as the goals to be achieved at each step of the way are determined based on a careful assessment by an optometrist whose practice specializes in analyzing and treating binocular visual behaviors, rather than focusing on simply remediating refractive conditions. The treatment can be in the form of exercises (vision therapy), therapeutic lenses or a combination of both.

In summary, eye exercises can not only be helpful in most conditions, but may also significantly increase an individual's effortless performance and efficiency. Setting appropriate goals based on a detailed analysis of an individual's visual behavior is of central importance in this process. Behavioral optometrists and vision therapists are the professionals who specialize in helping you set these goals and direct the stages of your effort to achieve optimum, measurable results.

-

I was recently tested and told I needed -5.00 lenses to correct my vision. I had been wearing -4.25's for the last 6 years. I wore -4's for 3 weeks before this exam. BTW, I scheduled this visit to get weaker lenses (-3.00's). As it turns out, I was finally able to get the glasses I had come for, but not before being told, repeatedly, that I didn't really want them! And being warned not to drive with them.

I have noticed that I no longer duck the gazes of people I am talking to. I have long been too uncomfortable to look directly at folks nearby when they are looking directly at me. I would sometimes become so anxious that I would completely lose my train of thought, my words just winding down to an incomplete sentence and silence. In order to avoid that, I would often make myself busy with my hands, so that I looked more natural while not looking at those I spoke with.

As I try to make some sense of this change, I see that people look softer, calmer, less critical to me now. Also, I notice they don't seem to loom over me. That part I can't explain. One attempt is remembering the adults who loomed menacingly over me as a child. And there were many. I once, as an adult of 34 years, had a panic attack while out with my husband and some friends. The reason? A young college student, that looked as if he might be on the football team, in the same dancehall/bar. To make matters worse, I must have stared, because in a few minutes he approached me and asked me to dance. I could hardly breathe, and couldn't lift my eyes to his face. I managed some kind of awkward refusal, then darted into the restroom. No one with me that night noticed, and that hasn't happened since, but it was an amplified version of what I experience with full correction.

Another thought: I have never gone to a vision specialist asking for an increase in my prescription, only when forced to replace broken or lost

lenses. Yet everytime I am examined, I am given a higher powered crutch. I have never been asked my opinion, and when I most recently pulled my courage together to request a reduced lense - I had to repeat that request, again and again. This practice needs to be examined. And I have learned that is is sometimes neccessary to repeat myself to be heard! :)

Your are implying that eye elongation is not the only factor causing myopic refraction, and that the refractive surfaces (cornea, lens) also play a part. Furthermore, you are implying that eye exercises can only affect the cornea and lens, but not the axial length.

The latter used to be my position before I joined this list. And largely it still is.

It's all a question of what's reversible. I used to be sure that axial length, once increased, cannot return to its prior, shorter, state. Discussions on the list about significant vision improvement due to vision therapy have resulted in some doubt creeping in. But I am still not convinced.

My previous paradigm was that of a BATTLE between functional and "anatomical" (mainly axial) myopia. Once the eye strain became excessive some of the functional myopia transformed into anatomical. Bang! There is no turning back. As long as one does not allow functional myopia to "spill over" into anatomical, myopia progression should be arrested. This can be achieved through weaker lenses, frequent rests while doing near-work, and reducing the load of near-work. All ideas of spiritual well-being also fit in here. It's another question if total spiritual balance alone can help stop the worsening of myopia. I know several people who feel depressed and lonely, do as much reading as I do (graduate students), and yet have 20/10 vision. And they don't even know of the plus lenses for reading thing.

The rapid initial progress to better vision following the start of VT can be attributed to the lens restoring its flatter shape after being bulged by the

strong power of glasses. But then what? You have to begin shortening the eye (I include some corneal flattening in the "lens" stage, think it's negligible ≤ 0.5). Is decreasing the axial length possible? That is the question. I used to be convinced it is not. Now I am not that sure. I would appreciate everybody's opinion on this. Some recent testimonials (Linda Lee, Feb 2; Mary Narlowe, Feb 4) suggest plateauing after some initial progress. The lens - axial length scenario? I think, yes.

Again, to reiterate my position, I favor undercorrection, no correction for small amounts of myopia, plus glasses for reading, spiritual unity. But this axial length snag puzzles me. As I recently said in a private message to an I_see member, if you drop a brick from eye level on your naked toe, it will hurt you, regardless of your spiritual elevation.

I am eager to hear your comments.

Torres,

Well I guess I was a bit luckier. I saw my optometrist last month, I told him about vision therapy and I gave him a bunch of documents that I picked up from ISEE's home page.

He agreed to go along with it and performed an incredibly thorough test, prescribed weaker glasses, and we agreed that I will see him once a month to see how I am going. He also asked me to document the kind of exercises I was going, how often, how long...

Currently I'm at L:-3.00, R:-3.75

I will continue with my exercises and tests for 6 months. If I do not see any substantial improvement (i.e. at least 0.75 to 1.00) then I would quit. I would continue taking care of my eyes but not with VT as a goal.

I must admit that sine I started my VT almost 3 weeks ago I only wear my glasses when it is absolutely necessary which is about 1/3 of the previous wearing time. I do not use my sunglasses at all (which was impossible for me

to do) and I seem to be coping fine.

Forget about you optometrist. Either find another one or tell him what you want to do. Make this your own project and control how it's progressing. (enough preaching!!)

I will post the result of my test to let the whole group know how I'm doing.

Subject: Vision Quest, step 2.

Well its been a while since I announced my vision quest in December when step 1 involved the confrontation of my optometrist with the ideas of eyesight healing. I saw him in December and its taking me this long to come to grips with accepting or actually not accepting his negative reaction. Its kind of funny, now that I think about it, that his reponse was such an emotional let down. Simply he said that my vision was too degraded (around -7.5 on both) for any of the "intense" exercises to work or have any effect. He did however said that it was totally up to me if I wanted to persue this quest. I am sad to say that I chicken-out at the time and got me the corresponding prescription on my new glasses instead of getting some that were decreased in strength. Now my courage is regaining strenth and will be taking another shot at these methods. It would be encouraging to hear from people who have actually gotten some if not great improvement in their eyesight by practicing these methods as discussed in the isee group.

Mario

Hi all...

When I was a kid, 30 years ago, my friend ordered a pair of those "X-ray glasses." Here's how they worked:

They were a cardboard frame, with two small holes, approx 1/4 inch diameter each to see through. Inside the hole were feathers, one placed in each eye hole. So, you were actually looking through the feathers. Feathers have striations in them. The illusion could only be done by looking at your hand with your fingers apart. The feathers made it so that the image of your hand turned into two images of your hand. The images overlapped slightly. The areas where the images overlapped were darker than the areas where they didn't. Thus, the illusion of seeing "through" your hand made it like you were seeing the bones inside your fingers. Definetly took some imagination.

Your hand was about the only thing you could see through. I guess you could see through a leg the same way.

Sadly, they did not work on clothes, but hey, anything to help science progress along its' forward path was good.

Isn't the internet great? Finally after having this knowledge for 30 years, I get to share it.

See ya.

Pediatric Ophthalmologist David Granet has put onto the web a cartoon that I think is offensive to kids with cross-eye. Dr. Granet doesn't seem to get this. If you are so moved, please check out the web site (URL listed in the following forwarded message, taken from the sci.med.vision newsgroup) and send a note to Dr. Granet telling him what you think of the cartoon. Better yet, post to sci.med.vision. And be sure to look carefully at "Calvin"'s eyes.

For some unknown reason I will actually break my own personal rule and *explain* something to Alex. The prelude to my page clearly states these pictures are for fun and that my home page is not a serious one. Moreover the Calvin and Hobbes picture you have obsessed over was drawn by my wife for use in a lecture I give to pediatricians as the beginning to a discussion of why kids have to wear glasses. Calvin is not cross eyed.

I understand why you have chosen to go after a cartoon on my home page - trying to pontificate outside your field of expertise and pretend you are an expert is getting wearing you out, so you are trying to distract.

An expert you are not, but transparent you are.

David

Vitamin supplements in the form of anti-oxidants and minerals are good for the body and the eyes, of course. I do not have the expertise to advise how much and which type, but I would think that the chemically altered foods we are getting in our diets can't be too good for our bodies (including our eyes).

From all the research and from experiences throughout history, the biggest push towards myopia is our near-centered sustained world in which we force ourselves to operate. Anything we can do to reduce this "stress" on our accommodative (focusing) system and on our convergence (pointing) systemthey work together...will be of benefit. The biggest push comes from the stress on the accommodative system.

One of the best ways to try to prevent yourself from becoming myopic (nearsighted) or to try to keep yourself from getting worse if you are already myopic, is to find a vision care practitioner who thinks and practices "developmentally and functionally" to evaluate your visual system at the near-area distance, as well as at the distance area and prescribe "counter-stress" lenses to be worn for the near area use (if they are indicated)...this includes lenses to be worn over contact lenses while reading/computer, etc. By reducing the stress the visual system will not have the push towards myopia.

Our body (and the eyes are not distinct from our body...but operates the same as the other body systems)..including our eyes, does not do something on a whim. Our body's structure changes due to stresses added or removed from it. We do not wake up one day and the eyes say, "Hey, I think I'll become myopic !!" Myopia is one way the visual system can achieve reading demands without having to focus as much..therefore the stress on the visual system has been reduced....but, now we have a structural change. Myopia is not just an inconvenience for distance seeing...it opens up the eyes for a greater chance of cataracts, retinal detachments, etc.

So, don't look towards nutrition as the major way to prevent myopia. Changing the environmental stresses (with counter-stress lenses, less lens

power at near, etc.) will be a much more true way to attempt to prevent or slow down myopia.

Another thing....very seldom do you need the same power of lenses (glasses or contact lenses) for near seeing that you do for distance. If you are myopic, you should, in most cases, have less power for your near seeing work. By definition, a myope needs less power at near to see (if he/she needs any power at all) than they do at the distance area. So wearing less power when you are reading is of benefit in most cases. But don't do this capriciously...have a good developmental vision care practitioner evaluate and prescribe the lens for the distance needed. If the practitioner you choose does not know or practice functionally/developmentally, choose another practitioner.

I am guessing that I am the youngest subscriber to this list (15), but I am very interested in vision therapy. I seek to improve my vision from it's current state (I don't quite remember, but I believe it's around 20/200 in each eye; nearsighted) through visual exercises.

I received my first pair of glasses when I was in second grade. I have always hated wearing them, and to this day, I only wear them when I absolutely have to (i.e., seeing the board, driving). My optometrist has continued since I first got glasses to progressively step up the prescription every two years or so.

Last year, I gave contact lenses a try. I got used to them after a while, but they were always mildly uncomfortable. About five months ago, I developed conjunctivitis (pinkeye), which prevented me from wearing my contacts for several months. I was given the go-ahead to wear them in January, but putting them on again only made me realize once more how uncomfortable it was to have two pieces of plastic floating in your eyes.

I have read over the I_SEE FAQ, but am not sure which exercises to perform. I don't expect results overnight, but in time, I seek to improve my vision significantly, possible up to 20/20.

I would appreciate any suggestions on how to start my vision therapy program.

Stephen.

Stefan,

In reply to your recent posting regarding the question of axial length:

I'm afraid i have no opinion on whether or not it can be, but i do have some questions to ask of you and the group.

Is the whole idea of axial length, which i guess means flatter or bulging cornea's (?) more than just a theory? I mean, how do you test something like this? Is there actually an instrument that can measure this and has this instrument been around as long as the theory has? And how does anyone know what the perfect shape for my particular cornea should be to ensure 20/20 vision. This isn't anything that anyone tested before i got glasses, so who can say what the shape should be? And doesn't this shape change constantly by a least a few millimeters (which i gather is all we are talking about anyway) every time i breathe, or blood moves around. Surely nothing in my body is precisely the same size for very long. Cells are coming and going constanly, aren't they? Doesn't every part of me get bigger and smaller as i age? Are my eyes even the same size, let alone the same shape throughout my lifetime?

Is it a case of - " well, we know how light bends and how vision works outside of an eye (in the lab) so therefore this is what must be happening inside the eye . . . the shape is all wrong. And when we adjust the shape with an outside lense, it is corrected so we know our theory is okay. " I am not trying to be funny here, i really want to understand how all this came about.

And the final thing that confuses me about all this, is these flashes of clear vision that us VT folk get from time to time. Mine came very early in my 'conversion' , and unfortunately hasn't

returned. My visual system completely lined up - axial length, muscles, lens, cornea, belief system, brain and whatever else goes into the mix - and, for about 15 second i could see with spectacular, bi-focal, clarity. From -7.5 to 0 and back in 15 seconds, that's my record!

I guess that's why i hardly ever ask myself whether or not axial length can change, because i know mine did. My big question ever since is - how the he#% can i get it to change back again, and stay there!

I appreciate the opportunity to discuss this subject with so many well informed and curious people. Oh, and please don't point me in the direction of in-depth medical studies. I don't know how to access them and probably wouldn't understand them if i could. If you could just summarize the results, i'll take your word for it. Thanks.

I beg to differ with this generalization. In particular, I think good nutrition is ESSENTIAL, if any vision program is to work. In all my ups and downs watching my vision, I have always found that vision is worse when I'm hungry, and often after having eaten "junk food". Under these conditions, no amount of eye exercises or near-vision avoidance will make me see farther! But often I will eat a carrot, say, and without my even thinking about it as "vision food", things start to get clearer. I don't think this necessarily has to do with beta-carotene. My distance vision seems to get a boost after eating any high-sugar foods too. This makes me think there is a link between myopia and low blood-sugar.

Several researchers found that low-protein diets correlated with myopia. See my paper on the prevention of myopia, at

http://silver.ucs.indiana.edu/~aeulenbe/i_see.html

Some even claimed success with an entirely dietary approach to myopia. Most researchers who found a dietary link to myopia seem to think that the deficiencies that would cause myopia would act by depriving the eye's tissues of nutrients; thus weakened, the eye would elongate. One researcher believed that poor nutrition would upset the salt-water balance in the fluids; this would affect the fluids inside the eye. According to his theory, a buildup of fluids in the eye leads to myopia or glaucoma or both, depending on the state of the tissues.

My feeling on the connection between food and myopia, based on my personal

experience, is that whatever foods help one's brain and muscle functions IN GENERAL, will help improve vision, and reduce myopia.

I say this because I have often noticed very rapid improvements in vision after eating certain foods. Some examples are mentioned above. Also, brewer's yeast seems to relieve eyestrain for me. For some reason, fasting appears to improve vision! Why this should be so I can only guess... it must have something to do with the altered state of consciousness releasing inhibitions. Nutrition has a profound effect on mood.

One more thing... I do not believe that myopia in the sense of "ciliary muscle cramp" is an "adaptation" to near work. It does not conserve energy, it wastes energy. Functional myopes are people who have their gears stuck in "high" ("close up") and cannot release them for some as yet undiscovered reason. The solution is not so much to avoid close work, but to keep those gears lubricated, in good working order. I believe proper nutrition is an important part of the answer.

I am sure that good nutrition is a necessary and essential prerequisite
to good health, which is not to say that it is sufficient of itself to
reverse or prevent bad health, including of course, vision health.

It could also be to do with the elimination of bodily toxins which some people believe happens when fasting.

Alex,

You mention the Eskimos study. My optometrist dismissed behavioral approaches because he (and most colleagues) believes this data to be anecdotal. I did not have a reply for his proposition, but I guess he meant that we can't draw very good conclusions from this study alone. Certainly you provide further evidence that supports conclusions from this data.

Any other thoughts?

Mario

Linda;

Just a few factoids about axial length and myopia reduction. Axial length is the length of the eyeball itself and can be measured with ultrasound very accurately and simply. I have seen in the clinic with ultrasound that 1 mm change equals 3 diopters (a person with -3 in one eye and plus 3 in the other had 2 mm difference in length between the eyes, which is the theoretical number, too) . There is lots of research with animals that correlates axial lengthening with myopia. It's really a simple mechanical relationship- the longer the eyeball, the more myopia (assuming a person is already myopic) What is intriguing to me however is what I read and heard from an optometry professor in Boston who also works at Harvard University with students who want to lessen their myopia and throw away their lenses. They do it with vision therapy, nutrition, exercise, relaxation, etc. She wrote an article in the Journal of the American Optometric Association this past year. I can find the reference if you like- it is not very technical- more of a personal odyssey article. She was a school teacher when she reduced her myopia (I think from about -4 to nothing). She was so excited, she went to optometry school and now teaches OD's and patients how to do this. There are many skeptics because, as I understand it, the people's eyes do not get any shorter and their refractive error is still on the myopia side, but their acuity changes for the better! No explanations really. I think it has to do with "blur processing" by the brain, but who knows?

This study only shows a correlation between myopia increase and "white man diet". However, other people, like me, believe just as strongly that these eskimo studies give support for the idea that the eskimo children brought up in a more modern society were exposed to more near point work, ie reading, than their parents, and thus became more myopic than their parents generation

Hello,

this a general inquiry to get an idea about what you think about the use of (+) lenses as part of a program to reduce myopia.

- * has anyone tried it?
- * any good?
- * how do you decide how dtron/weak they should be?
- * when/how often do you wear them? and for how long?

I'm interested in personal experiences rather than historical experiments.

thanks
George

I started with VT excercises -- moved on to resolving emotional issues as best I could -- mastered relaxation techniques -- and now am at the nutrition/neuronutrition stage in my vision quest. Here's why:

1. What has been said of protein deficiency being possibly linked to myopia makes a lot of sense to me. Low protein=amino deficiencies=impaired production of neurotransmitters and brain hormones=impaired function of pituitary photoreceptors, aberrations in circadian rhythm and light/darkness sensitivity, changed amino profile of the retina, low production of serotonin (a player in contrast sensitivity), lens and vitreous clarity disturbances (cysteine deficiency and/or abnormal metabolism of tryptophan), and possibly lots of other things I'm just beginning to figure out. Also makes sense in the light of the only case history I've studied inside and out. As a kid with perfect vision, I used to be a carnivore, plain and simple. I had classic stone age tastes in food: I wasn't interested in anything but meat and some fresh fruit. A lot of coersion had to be (and was) excercised to feed me even the smallest amount of carbohydrates. However, sugar cravings and general interest in carb foods appeared at puberty and chronologically coincided with the onset of myopia. Sugar, btw, among other thins, is an addictive shortcut to serotonin (so Alex, that explains why your vision is better after a sweet meal) and one of the surest ways to deplete it to an abnormal low afterwards.

2. I conducted an amino experiment on myself creating a big serotonin surge via acetylcholine pathways (don't try this at home) and had a 20/40 clear flash that lasted for several hours uninterrupted. I would live like that forever but it has made me dangerous -- people can't normally function on a daily basis feeling this happy, there's simply no social niche to accomodate someone who feels this way. Besides, I wouldn't really want to be taken for a crazy junkie who achieves similar effects with some horror powder or other.

3. Vitamins and minerals, in addition to their other functions, are in many cases synergists or co-factors in a lot of neural processes; some reactions will be impaired even if there's a one-vitamin deficiency.

4. A lot of vague ideas too shapeless yet to be argued. Lutein in the macula... and in marigolds (possible supplement?)... Taurine concentrations in the retina... Blurry vision in severe depression... God I wish I knew everything. Working on it...

Elena

The device itself is interesting. I have had one for nearly 15 years. My understanding is that there are only about 200-250 of these in the world. Mine is number 15.

I feel that the claims made by the manufacturer and inventor were overstated. The instrument by itself will do nothing to a person. VT is something that the person must do for themselves. The Accomotracs is an instrument to provide biofeedback to the person using the instrument to "know" or to "get a sense of" how they are focused.

40 times a second an infrared system based on a Badal optometer

measures accommodation and converts the measurement to a sound. The sounds then changes dynamically with accommodation. By working the sound higher and higher the person is learning to harness negative accommodation again and can, at first, for short and then for longer and longer periods of time dynamically focus at distance and clear things up. At first the refraction does not change only negative accommodation. Over time (6-8 months) the refraction does begin to change.

Problems with the machine include the fact that it is best used in a dark room with the person staying perfectly steady. Even the slightest movement causes the system to go out of alignment changing the readings in a way that has nothing to do with the level of accommodation the patient is using. It also only measures one eye. Some of us have wondered if it really is measuring accommodation or is just a very expensive pupillometer registering instead the total amount of light reflected back to the instrument rather than accommodation??? Anyway, the pupil changes generally parallel the lens changes but I would like the thing to be cleaner than it is.

IMHO, used alone for VT for myopia control (as was recommended by the inventor) will not provide lasting changes. We use it as an additional tool as part of a much more complete myopia control program. Different people react to different activities and using only one means that some won't get the effects necessary and those that do may not get as much change as is possible with a more broad approach.

Lastly, there is an alternative instrument from England called the Laserspec which uses a laser speckle pattern machine which gives direct visual feedback as to where one is focused in space. It is less expensive and has none of the limitations of the Accommotrac.

As to your last point, I know of OD's doing VT in North Carolina but I do not know who has the device. If you want a list of those with the Accommotrac you can contact Dr. Joe Trachtman in Brooklyn NY.

Paul Harris, O.D., F.C.O.V.D., F.A.C.B.O.
Director, Baltimore Academy for Behavioral Optometry

This Optometrist's name is Antonia Orfield and she wrote the forward to my
book *The Power Behind Your Eyes*. I enclose a few juicy quotes from the
article that actually appeared in the *Journal of Behavioral Optometry*.

Seeing Space - Undergoing Brain Re-Programming To Reduce Myopia
by Antonia Orfield O.D.

Significant quotes from paper published in the *Journal Of Behavioural
Optometry*, Vol 5.1994. Page 123-131.

Functional Myopia is not just an imbedded (accommodative) spasm and it is
not just an enlargement of eyeballs. It is a reflection of the shrinking of
the brain's space world by closure of the periphery, first by stress, then
by errors in spatial judgement induced by minus lenses.

(Visual) habits and the (minus) lenses have programmed their brains to
think of vision as looking at something and seeing only that. To cure
myopia, one has to re-program the brain to see space.

Plus lenses for myopia

- *Subject:* Plus lenses for myopia
 - *From:* Alex Eulenberg <aeulenbe@indiana.edu>
 - *Date:* Thu, 8 Feb 1996 17:15:42 -0500 (EST)
-

Someone wrote asking for experiences with plus lenses to treat myopia -- "no history or scientific studies, just personal experiences." Well, that I can do!

My personal experience has been that plus lenses produce an immediate "upgrade" in distance vision, after several minutes -- or sometimes several seconds of wear. Unfortunately, the effect is usually temporary. But it's significant, and much more reliable than anything else I've tried to get a "clear flash".

At first, putting on plus lenses can give you headaches, because your convergence and accommodation functions are set off-balance. I used to feel a "pulling" sensation on my eyes when I put them on. I also noticed a new "snappiness" to my eye movements when I took them off.

How I have used them:

- 1) at the computer
- 2) reading books
- 3) just sitting around
- 4) walking around campus.
- 5) while practicing Bates-style exercises

Yes, at my last "official" eye examination, I was prescribed -1.25 glasses. Yet, I am able to get around with +3.25 glasses on, with no discomfort, only mild blur. With +1.00 glasses, things are almost normal. Even in the dark!

However, at first the glasses caused major disorientation, and I certainly wouldn't recommend walking around with plus lenses (much less driving, operating heavy machinery, etc.) if you're a myope, unless YOU feel comfortable. Wearing a patch over one eye seems to lessen the disorientation; this is probably because it eliminates the need to

converge. It also provides the unused eye with some rest. You might even think of it as a substitute for palming. The covered eye actually does become "fresher" (gotta see it to believe it). If you do patch, though, do remember to alternate!

I started out with "mild" myopia, and by the time I started trying out plus lenses, I already had made quite an improvement, and had reached a plateau. Plus lens therapy gave me a little push. One day after intensive plus-lens wearing I was able to read the 20 line at 20 feet indoors. But otherwise, I've stabilized at 20/40 indoors and 20/20 outdoors (on good days). When my vision starts to slip, I often put on a pair of plus glasses and look around the room, focusing on small details. This usually sharpens things up.

My philosophy on plus lenses for myopia is that they are best used for STIMULATING DISTANCE VISION, and not for "reducing stress of near vision". This is because I believe that the optical cause of myopia is not overuse of near vision but underuse of distance vision.

For the ultimate work on plus lenses as a cure for myopia, the series of books by Jacob Raphaelson is a must-read.

See the "Alternative Eye Science" bibliography at the I SEE page for references.

I have a problem with double vision along with myopia. I would like to find a professional to help me with my vision training. If anyone knows of someone in the North Alabama area who practices vision training, please email me at gturner@traveller.com or post a message to the list for all to see.

Thank You,

Glenn

True, plus lenses relieve the crystalline lens from the accomodative stress and it flattens after being bulged due to near-work focusing requirements. As you note, there is almost instantaneous improvement in vision. Plus lenses are essential for arresting the progression of myopia. But they are almost powerless in reversing its course.

>I started out with "mild" myopia, and by the time I started trying out

The axial length "reverse rigidity" theory. See earlier post "Can axial length be reduced?"

Temporarily. Again, plus lenses are helpful in stopping myopia from worsening but can do little in terms of its reduction.

The bottom line is that to reduce myopia one has to either flatten the cornea or reduce the axial length. Refractive surgery and orthokeratology aim at the first, I am not aware of any technique that addresses the latter (muscle exercises? - unlikely). The neurological aspects of vision that

Elena is passionate about are another dimension which does have its important role. I think clear flashes are more of a neurological than optical phenomenon.

It might be useful to give another perspective of plus lenses. Firstly, recall that every time you reduce a minus prescription you are creating a plus effect. Antonia Orfield says: ".....space world has shrunk down to primarily central vision, so that they cannot judge distances. The (minus) lenses induce such warped vision in the periphery that their brains have to screen it out.....Lenses deepen their discoloration in space."

Plus lenses spread light over the peripheral retina. This activates the peripheral space monitoring system of vision. In *The Power Behind Your Eyes* I have suggested, after discussions with Harry Serota O.D., that the retina is the connection to the brains's FEELING centre and emotional wiring of our vision. This means to wear a strong minus lens contributes to a loss of a feeling sense of vision. To wear a plus lens is to activate retinal vision which means we bring more feeling to what we see. Also, the plus lens acts as a parasympathetic stimulant, thus inducing relaxation through the autonomic nervous system, thus reducing the flight or flight response. Perhaps this is why emotionality is activated when we cut back the minus lens prescription. The amount of cut-back from my research is between +0.5

Even those ODs who seem to be satisfied with the traditional explanation of myopia are careful not to talk about axial lengthening as the "cause" of myopia if they know any better. Nowadays, the more suave way to put it is a "correlation." It's been years since I've studied formal logic but I do seem to remember that the rule of thumb is not to confuse correlation with causation. ("Let's not invite Joe to our barbecue -- whenever we invite him, it rains." This is a classic example of the approach taken by ophthalmology: because rain has been observed when we invited Joe, Joe is the cause of rain.)

Now for the facts.

1. Abnormally long eyes that `are_not_myopic` have been observed.
2. Eyes of normal length that `_are_myopic` have been observed.
3. But in many cases, "abnormally long" and "myopic" do coincide. That's `_coincide_`. Not the same thing as "lengthening causes eyes to become myopic." Nor the same thing as "myopia causes eyes to lengthen."

I see myopia as an incredibly complex phenomenon. Axial length is just one parameter involved. The fact that it has attracted an unfortunate and truly unwarranted amount of attention from the sluggish, rigid, and intellectually inert eye-care establishment, to the detriment of studying other phenomena, doesn't make it THE phenomenon behind myopia. I used to believe it was -- spent 25 myopic years believing it -- just because I myself was too lazy to think hard. Come on -- there are individual differences in functioning of virtually every organ in the body -- different physiological solutions, via different organic mechanisms -- that don't seem to surprise anyone if there's a scientific explanation available -- or, alternatively, just pass for miracles if there isn't. But in fact when we're dealing with individual solutions we're dealing with the norm, not the exception. This norm is so wide-spread that no one notices anything unusual about not catching a bug when all the family is sniffing and coughing, not getting salmonella poisoning from the same sushi that has knocked out two of your dining

companions at the Mount Fuji, or just being a brown-eyed descendant of four generations of blue-eyed ancestors. A thyroid condition can get compensated or decompensated depending on the amount of iodine in the drinking water, as well as the amount of work-related stress. An overweight woman produces some estrogen extraglandularly, in her fat tissue -- something her thin counterpart can't expect her body to do. A smoker fouls up her lungs but gets a superb protection against Alzheimer's (not a widely advertised fact, btw -- God forbid we base our personal health choices on complete information). Bjorn Borg, one of the greatest tennis champions of all times, had a basic heart rate and blood pressure normally associated with coma. As a kid, I won some local gymnastics competitions two years after breaking my left elbow and shoulder in three places and being told that I would always have difficulties with simple two-hand tasks like tying my shoes. I was shown the X-rays and given a scientific explanation as to how my arm won't be able to function properly. I'd love to use it right now to give the guy who did the explaining a good punch in the nose -- no hard feelings, just to show him how well it can function.

Multiply your individual body by your individual environment, put it to the power of your genetic composition and your lifelong experiences, and you'll calculate your exact physiological response to a given stimulus... easy isn't it?! Still, something in your head finds it easy! The only problem when communicating with your unconscious is, does it want the same thing that you want? Vic suggested ordering your unconscious about ("I want my clear vision NOW!") -- a fine idea, provided your unconscious is eager to cooperate. But what if it has a mind of its own? What if it doesn't see you as the boss?.. That's why coming to terms with all levels of "you" is essential. Those other levels, deeper than your thinking layer, are powerful as hell. You have no idea what they are capable of doing if they want to serve you. Or if they want to overthrow your rational rule. Give them an incentive to serve you -- and beware of pissing them off!

If shortening the axial length were the only way away from myopia we might indeed be doomed. That's if it's impossible to shorten it -- of which I'm not so sure, because if, for instance, you feed the back of your sclera stuff that will make it thicker, even plain old gravity might get involved in reshaping your eyes. Plus the extraocular muscles that will stop pulling and start pushing if you teach them how. Plus extra blood/oxygen supply to the retina that will activate the starved, idle cones, compensating for the poor quality of image by sheer quantity of receptors involved. Plus the most important player -- your mind: try telling it it's all right to have axially long eyes, try telling it it doesn't matter as long as it can get the picture right utilizing other pathways -- its spatial intelligence, its experience and memory, its integrating and interpreting skills, intuition, imagination, emotional feedback -- a pleasure-reinforced "right" picture and an emotionally discouraged "wrong" one... and also all those mystical powers you're too well-educated and sophisticated and skeptical to believe in but

know in your heart of hearts that you HAVE! You're too embarrassed to admit it... but you know your mind has that extra something... you don't have to name it, you don't have to science-proof it -- just trust it and let it work for you. I do hope I don't start sounding like a faith healer at this point. But even if I do -- so what? It's faith in myself -- and "myself" is a very real phenomenon in terms of what it can do for me. As well as what "thyself" can do for you, my friends.

Elena

While reading thru the I_See FAQ's, i came upon the definition of this condition - tensing up of the cilliary muscles causing blur ...

I was reminded of my situation when i started to wear glasses. I had just moved to a new, tough school and became the unwitting victim of a group of older girls who didn't care for me. I would have to say that i 'excessively accommodated' them by attempting to become invisible. While we lived in that town, i stayed home and read books. Fortunately, we only lived there a few months, but by then, i was wearing glasses. Too bad i didn't know anyone who could help me to deal with bullies.

Further in the FAQ's, i read that the standard treatment includes temporarily minimizing near work, and rest to allow the cilliary to recover. I expect this means patching each eye? I remember that i used to patch each eye when i began VT, and found it soothing. I can't remember exactly why i stopped, but i think i read that it was not a good idea to patch an eye for more than four hours a day.

Does anyone have any experience with patching? I would appreciate hearing about it.

On a totally unrelated topic, what are these plus glasses that everyone is talking about? Do you mean those reading / magnifying glasses i can buy at the drug store or glasses prescribed for far-sightedness? I feel like i have joined this conversation in the middle. Can someone help me out with some background, please and thanks.

Linda Lee

I regret to see that my writings about the role of axial length are being taken so literally. What was a wave-like, "de-selfed", "objectivized" (meaning transforming one's feeling and knowing self into an eye) statement is countered with some junior school attempt at logic.

Of course, generally, it is correlation between eye components that matters. And this notion has not been around since "nowadays" but well since at least the middle of last century when eye models were developed (e.g. Gulstrand's) and measurements of eye parts initiated.

When you take an individual eye, it can grow structurally myopic by two ways: either by increasing the curvature of the cornea or by elongating along the anterior-posterior axis. I hold that the corneal curvature is

relatively stable. It is the axial elongation that is the culprit for myopic progression. Now, to avoid the danger of being taken again too simplistically, there is nothing like absolute axial elongation, that is just by itself. There is always something behind it. That many optometrists and ophthalmologists see axial elongation as an unrelated or limitedly (mainly to visual tasks) related event, I agree with Elena, is deplorable. I also agree that given a certain refractive state of the eye there are other factors that can affect the quality of vision - neurological, histological, whether you have faith or not, etc.

You can link EVERYTHING to your vision, from near-work requirements to spiritual maturity to your attention to detail to the way you make sex (Am J Ophthalmol 01/96) to your psychological type to what you know and don't know to ...

Actually, in my book, the two are quite related. Both can help relieve the eyes of strain and excess contraction at the near point, and both can improve distance vision. I think they both can help you overcome astigmatism as well (judging by my experience, and some comments by Jacob Raphaelson, OD, author of "Stretch Your Eyes" and "Spectacle Hobby").

"Plus glasses" are glasses with convex lenses, measured in positive diopters. Yes, these are the ones sold at the drugstore for \$10-\$20.

Although they make things look larger and nearer, when you look through them, your eyes are actually required to focus less strongly. If you are used to wearing "minus glasses" for myopia (say -6.00 D), reducing the minus will have the same effect (i.e. wearing -4.00 D instead). In effect, they allow you to "flex" your focusing muscles even as you read. If you must spend most of your time looking at close objects, plus lenses will help you get your daily allowance of distance vision. If you have a low amount of myopia, things in the distance will look especially blurry through plus lenses. This gives the eyes extra stimulus to focus outwards.

HOWEVER,

When you use plus lenses for close up work, your eyes still have to converge. This takes extra energy too. Plus, the act of converging is neurally linked with the act of focusing. You are sending your brain

contradictory signals whenever you change the amount of focusing without changing the amount of convergence. I think this is the reason why it is hard for many people to read without their minus glasses, even if things are perfectly focused. They see double because their eyes want to uncross, given the fact that they are focusing for the distance. The same thing happens if you don't wear glasses for your nearsightedness, and then start wearing plus lenses. You will get a bit dizzy.

One way around this is to put a patch (also available at the drugstore) over one eye, allowing the eyes to look parallel. This increases the comfort. Also, since one eye is resting, the other eye gets more energy. Plus, the patched eye's retina gets to recharge. You will know what I mean if you try this. Things look much brighter with the previously patched eye after an hour or so of work like this. Sometimes it seemed that it was the patched eye that improved, not the one "exercising"!

Things you should know...

I have found that after patching I get a double vision that lasts a few seconds.

The worst thing about patching is having to explain to the people at the office what you're doing. They'll think your crazy. On the other hand, maybe if enough people start doing it...

I have experienced immense improvements in acuity simply by wearing plus lenses and a patch all day, and alternating the patch. This took a lot of discipline, involved some risk (only one eye, and my world was more blurry than normal), and socially was quite a burden (what will passers-by think?). But with this method I was eventually able to see 20/20 in an artificially lighted room, whereas I had once required a -1.50 prescription to do this.

I have regressed since then, but now that the topic has been brought up again, maybe I'll start doing it again. As I said, it takes a lot of committment!

Guidelines for adding plus: add as much as you are comfortable with, given your work environment. If you can go without glasses, you are lucky. You can go to a drugstore and experiment. If you do wear glasses, you can actually put plus glasses over your prescription glasses. Perhaps you don't want to do this in public. But at least this way you can get an idea what to ask the optometrist for. Say you are wearing -4.00 glasses, and you are comfortable wearing +1.50's over them. Ask your doctor for -2.50 "reading glasses". Even then, I would still try-before-you-buy. Ask for trial lenses.

Guidelines for patching: I've heard it said that up to 4 hours at a time is "safe". Robert-Michael Kaplan in his book I believe says that 4 hours is "optimal", this is the point of diminishing returns. If you have lazy eye or double vision, check with your doctor. Be sure to alternate the patch!

Subject: Re: MYASTHENIA GRAVIS ASSOCIATED WITH ASPARTAME USE

Aspartame marketed as NutraSweet/Equal/Spoonful, etc. is increasingly triggering myathenia gravis. The following article by Dr. H. J. Roberts shows the link. Many times the victim will become almost asymptomatic when they eliminate this toxin. This article is presented so that those having this problem will know one of the probable origins.

Myasthenia gravis is a rare autoimmune disorder that affects the transmission of nerve impulses to the muscles. The first sign that something might be wrong is the appearance of drooping eyelids. Other symptoms include double vision and problems eating, speaking and swallowing. In some cases, mobility is affected because of a general weakness in the arms and legs.

The exact cause of myasthenia gravis is unknown, however, it does appear as though some factor causes the immune system to turn against muscle tissue. A possible link to the thymus, a component of the immune system, has been discovered. Now that we know some of the cases are triggered by NutraSweet which destroys the nervous system, the optic nerve and ravages every organ of the body, at least some people can eliminate their problem by knowing to abstain from this toxin.

I've personally run into several people with the drooping eyelids and in every case they were using NutraSweet.

+++++

By: H. J. Roberts, M.D.
Senior Attending Staff
Good Samaritan Hospital and St. Mary's Hosp.,
West Palm Beach, Florida
Director: Palm Beach Institute for Medical Research

Published in the Townsend Letter for Doctors, August/Sept. 1991

SUMMARY: Myasthenia gravis (MG) developed in three patients who consumed moderate to large amounts of aspartame (ASP), a popular sweetener. In addition to ptosis and marked muscle weakness they evidence complaints encountered in other ASP reactors.

The criteria for such an association included (1) the onset of symptoms after using ASP, (2) a diagnostic response to intravenous edrophonium chloride, (3) gratifying improvement of the ptosis and muscle weakness following ASP avoidance and pyridostigmine bromide therapy (with subsequent discontinuation of pyridostigmine in two), (4) the prompt improvement or disappearance of concomitant complaints when ASP was stopped, and (5) predictable exacerbations on ASP rechallenge.

Four persons who completed a nine page questionnaire as part of a nationwide survey of aspartame reactors also had been diagnosed as having MG or probable myasthenia.

The consumption of aspartame in patients presenting with MG since 1982 (when ASP became available), and the incidence of MG since 1982 require study since these unexpected observations, if confirmed, offer new insights concerning myasthenia.

The pathogenesis and rational treatment of myasthenia gravis (MG) are not fully understood. A suspect association between the use of aspartame (ASP), a widely used sweetener and MG was unexpectedly encountered in three female patients. All evidenced other of the complaints more commonly experienced by ASP reactors. Four additional patients with MG or probable MG also were found in a nationwide survey of ASP reactors.

Observations

Seven women who met the criteria for ASP reactors were diagnosed as having MG or probable MG. They ranged in age from 31 to 82 years.

The three patients who were personally attended had diagnostic response to intravenous edrophonium chloride (Tensilon). All experienced gratifying improvement after ASP was stopped and pyridostigmine bromide (Mastinon) prescribed. Two subsequently were able to discontinue pyridostigmine.

The four persons who completed a nine page questionnaire as part of a nationwide survey of aspartame reactors had evidenced ptosis in one or

both eyes. The muscle weakness in two almost precluded their rising out of bed without assistance. The ptosis and severe muscle weakness in the other two had been ascribed to "aging".

The following features were present in all seven patients.

*Each had consumed moderate to large amounts of ASP as soft drinks, cola beverages, tabletop sweeteners and other products prior to the onset of myasthenia symptoms.

*All had multiple neurologic and systemic complaints comparable to those in the author's larger series. The former included severe headache, dizziness, memory loss, confusion, intense insomnia, grand mal convulsions (80 cases), pathologic drowsiness, paresthesias, slurred speech, atypical facial pain and marked tremors. Most improved within several days or weeks after avoiding ASP.

*These ASP-associated symptoms predictably recurred on aspartame rechallenge, known or inadvertent.

*The majority had seen at least one ophthalmologist for "trouble focusing the eyes," and were told that no intrinsic eye problem could be detected. The patient cited in the case report came for medical clearance prior to anticipated plastic surgery for her ptosis.

Representative Case Report

An active 82 year old woman with insulin-dependent diabetes had been in good clinical control for several years. She presented with dropping of the right eyelid, which she had to elevate manually - a finding not noted previously. An ophthalmologist recommended surgery to "pull up the skin". Other recent symptoms included severe memory loss, confusion, dizziness and insomnia. Concomitantly, her fasting and random blood glucose concentrations by home monitoring rose in spite of careful adherence to her diet and appropriate adjustments of insulin.

The patient had been consuming considerable ASP recently. Within one week after abstaining from such products, her complaints improved or disappeared, except for the ptosis. Her diabetes also came under prompt control. There was a dramatic response to intravenous endrophonium and ptosis improved on pyridostigmine therapy. When she attempted to discontinue this drug two months later, it recurred...necessitating resumption of the medication.

Discussion

The ability of one physician to find seven documented or probable cases of MG among ASP reactors ought not be dismissed as coincidental or anecdotal. The validity of this association is supported by the prompt regression of concomitant neurologic and systemic complaints after avoiding ASP and their predictable recurrence following rechallenge. Accordingly, patients who complain of severe muscle weakness, ptosis and difficulty in focussing the eyes warrant a diagnostic trial of ASP avoidance.

The precipitation or aggravation of latent MG by ASP may be due to pathophysiologic changes induced by this chemical or its three components - phenylalanine (50%), aspartic acid (40%), and methanol (10% by weight). They might include effects on muscle or the neuromuscular junction, altered metabolism of major neurotransmitters, methanol-induced neuronal edema, and glucopenia within nerve and muscle tissue from amino acid-induced insulin release and the frequent concomitant decrease in caloric intake for attempted weight loss.

The public health implications for a chemical that is being consumed by more than 100 million persons in the United States with such neurologic psychiatric and behavioral reactions are apparent.

If others confirm these observations, this influence of ASP and its components on cholinergic transmission, as well as noncholinergic mechanisms and drug therapy, warrant intense study. For example, in addition to enhancing cholinergic tone, pyridostigmine also increases both basal and growth hormone-releasing hormone-induced growth hormone secretion. Similarly, a therapeutic problem may be encountered owing to possible interference with the action of pyridostigmine and other drugs by ASP. This phenomenon has been encountered with phenytoin, coumarin and insulin (see Case Report) among ASP reactors.

Well I just don't know how you can see through plus lenses.

I'm currently at -3.00, -3.75 and I use -1.50, -2.00 glasses. If I put on +0.5, +0.5 glasses things that are readable with my naked eyes become blurred. My computer screen is about 22inches away and I can barely see the characters. With the plus glasses that become impossible. So How could you use them for close-up work if they make things worse? or would things clear up later?

thanks
George

surprisingly things clear up in minutes. you just sort of relax and wait.

Vic

There is no absolute value of plus which can be recommended for every situation, much less for every person!

I find that about 2 diopters of myopia is about the perfect amount for working at the computer, meaning that I, as a 1-diopter myope, am comfortable wearing a +1.00 lens. To get the same effect, a person whose vision is corrected by a -2.00 lens would simply go bare-eyed. A person with a half-diopter of myopia would wear a +1.50 lens and a person with 3 diopters of myopia would wear a MINUS lens: -1.00. Now these are just extrapolations based on my experience. Note that I am talking about considerably more "plus" than what is normally advocated by optometrists who prescribe reading glasses for "nearpoint stress relief". Here, the idea is to "give your focusing muscles a good stretch". 2 diopters of myopia means your maximum distance for clear vision is 1/2 meter. It means that when you are looking at an object 1/2 meter away, you are working at the "far point" of your range of vision. 1/2 meter for me is a comfortable working distance away from the computer. It may not be the ideal distance for you.

I have a +1.00 pair and a +3.25 pair. The +1.00 is best for the computer, while the +3.25 pair is best for reading in bed. Sometimes I look around

the room in the +3.25 pair (WARNING! Walking around with a lot of plus can be dangerous, especially when waling down stairs!!!) for a quick burst of clarity which kicks in, remember, when I take them off.

Dr. Kaplan mentioned something about plus-lenses focusing more light on the periphery of the retina. I hope he can expand on that a little.

One thing I have noticed walking around with plus lenses is that, despite the increased blur, I have LESS of an urge to squint. As a matter of fact, I get a soothing feeling as if my eyes are "widening". I have no explanation for this. It must have something to do with that peripheral enhancement Dr. Kaplan was talking about. If others try and experience the same thing, I'd like to hear about it. Or if you experience something like this when you take your minus glasses off.

--Alex

A few months ago one of my wife's eyes started to become red, watery and heavy. This usually (but very hard to confirm) after working on the computer which she's been doing for years.

She has 20/20 vision and never wore glasses. She went to the doctor who prescribed some eye drops and +0.5,+0.5 glasses. She used them for a while. Her condition came and went few times and it seems that the glasses are not helping (actually they're not comfortable).

Now the eye is red again and the eyelid is heavy in other words it's movement up is slow and doesn't open all the way up.

It seems that the only thing that relieves her eye is washing it with saline solution.

Has anyone experienced a similar thing? Any ideas as to it could be?

many thanks
george

I am told I need -5.00 lenses to see 20/20. I am wearing -3.00 disposable contacts, and using +1.25 glasses at the computer (the screen is about 16" away). For reading the paper or books, I usually use +2.00 glasses and gradually move the reading material away from me, to about 17". On the days when I use no contact lenses, I usually skip the Plus lenses as well.

I am finding that I spend an enormous amount of time decoding the printed word, in one form or another. I am trying to wean myself away from this dependence - I feel it is a superficial, isolated way to live. I want to be able to sit quietly with my own thoughts, with out feeling the panic, and grabbing yet another book to distract me. I wonder what could be so scary?! I don't think I have been without a book in the past 26 years!

The idea of cutting back is frightening; it reminds me of the feelings I had 10 years ago, when I left behind a three-pack-a-day cigarette habit. What will I DO? My mind races around that same way. I learned a few years ago that smoking suppresses emotions; there are 12 step meetings set up to deal with the emotions that surface when smokers quit. In my research on vision improvement, I have found the same claim - that the use of minus lenses supports suppression of emotions. So I guess this is my support group.

Thanks for letting me share <g>

I have experienced the same droopy, red (usually one more so) eye thing, off and on for the last 3 years. I wrote it off as dry eye and allergies. As part of my self prescribed vision improvement program, I began taking Bilberry and Eye Bright suppliments. I take 2 capsules of each 2 or 3 times a day. The improvement in the (now) whites of my eyes is amazing! No more red spiderwebs. I also have noticed the eyelids working together (no droop). I can't tell you which caused the improvement, but my guess is the eyebright - the bilberry is for night vision. I also added a halogen light to my computer work area (I, too, find the CRT most straining). I hope this helps.

Behavioral Optometrists have for many years speculated what happens in the brain while looking through plus lenses. Plus or less minus, the same thing, defocuses light on the fovea centralis, the only place where 20/20 can happen. I call this minute point on the retina the logical focus centre. This is contrasted to the retina which I equate to the feeling centre. A plus lens by defocusing light causes blur on the fovea and the dispersed light activates the peripheral retinal network of fibres. The behavioral equivalent is to see more, feel more and look less. This means paying attention without straining to look clearly. This is equivalent to seeing through eyes of intuition as apposed to looking from logic. One's whole behavior goes through a shift. You look without effort and allow the world to come to you, rather than trying to foveally grab it. BTW., this is true farsighted vision! Enjoy.

Just back from an optometrist's office. Did everything to show my worst performance (not on purpose -- just had no time for any better): no tricks of the trade -- no palming/sunning/yoga/bilberry/aminos, no plus lenses; spent the whole morning driving, wearing my strongest glasses. During the exam, noticed that the device you look through actually doesn't allow you to BLINK -- which makes a lot of difference, since my focusing for a clear flash invariably rides on precise blinking techniques that have taken me six months to develop and perfect. The office was very dark. I had no clear flashes and didn't come anywhere near the kind of clarity I now have 50% of the time. So the "objective" improvement didn't appear as great as I expected but still the ophthalmoscope measured less 1 diopter of myopia in both eyes and less 1,5 and 1 diopters of astigmatism (to zero cylinder in my left eye and 0,75 in my right one.) The doctor, new in town and eager to please, didn't give me an especially hard time, limiting herself to just a brief lecture on how "Bates has been totally disproven" and how I was probably overcorrected by the previous doctor. (Yeah right -- all the way to 20/70 that I used to have prior to VT in the glasses I came in wearing. They were initially prescribed for 20/40 but that didn't last -- as usual.) Anyway, I kept nodding and agreeing and being very humble, and got rewarded for my humility by two prescriptions for weaker glasses. I left the pair I use for computer work in the office to update the frame, so now, after palming/yoga/bilberry/etc., etc., I'm writing this with no glasses on, my long stable clear flash rightfully reestablished (and no, I'm not pathologically close to the screen -- a little closer than comfortable but still OK.) Well -- I've started official record-keeping..... If I knew how to achieve a non-blinking clear flash it would have been far more spectacular. Still I'm not too disappointed: for one thing, I now know for a fact that whatever they measure in the office isn't very informative because you're prevented from demonstrating your best acuity; for another, bye astigmatism (I'm sure I'll take care of the rest of it pronto); and, finally, my eyeballs are now officially shorter.

Elena

Mary and George: We just yesterday put on the network a report about aspartame and myasthenia gravis by Dr. H. J. Roberts. That what this droopy eyelid is usually - thats how it is identified. Are you both using it? Also, a couple of months ago Alex put Dr. Roberts report on the network having to do with dry eye and aspartame.

Just heard the news today that NutraSweet (aspartame/Equal) is changing their name to Benevia. We're checking that out on their web. So be warned if you see anything with that name. Remember this is poison to the eye because it has wood alcohol in it and as Dr. Roberts said on radio January 28 it destroys the optic nerve, causes retinal detachments, blurred vision, black spots and blindness for starters.

For anyone who perhaps is new to the network who want Dr. Roberts position paper on aspartame and the eye or other information on the eye and aspartame it is on our auto-responder. To get a directory you simply have to put sendme help in the subject line like this:

Subject: sendme help

When you get a directory you simply have to put sendme again in the subject line with whatever report you want to access exactly as typed on the lefthand side of the directory.

If you didn't see the report on myathenia gravis yesterday email me personally and I'll send it to you.

Regards,
Betty

To get more information on aspartame, email betty@pd.org as follows:

Subject: sendme help

The subject line must be typed exactly like the above line.

Betty Martini 1. Take the 60-day No-Aspartame test
Mission Possible and send us your case history.

Re: Red and heavy eye

PO Box 28098
Atlanta GA 30358

My wife doesn't use any of this aspartame/NutraSweet stuff. Her diet hasn't changed to sort of link it to her condition which started about 6 months ago.

The redness is only in the left eye, never in the right one which tells me that it's not diet-related. (How's that for a logical conclusion :))

A couple of days ago she started taking some of the Bilberry tablets that I'm using and I will tell her about Mary's experience with the eyebright of which I have a jar-full.

It's funny that doctors try to blame any condition you have on allergies, and stress. A friend of mine called me few minutes ago to tell me that he's got a middle-ear infection. The doctor told him it might be because of fatigue, stress, travel....

BTW, is this NeutraSweet stuff being used in candy or chocolate under a different name?

thanks
george

Blur Vs. double vision

- *Subject:* Blur Vs. double vision
 - *From:* "George Tohme" <PolySoft@msn.com>
 - *Date:* Tue, 13 Feb 96 06:54:23 UT
-

is blur (what myop experience while looking at distant objects) somehow related to double vision?

This question was triggered a couple of days ago when I was talking a walk. There were three high street light poles along the road. When I looked at the first (closest) pole it appeared as if it was 2 poles parallel and pretty close (almost touching one another). I looked at the second one (abit further away) and I could see the same thing only the 2 were more apart. The third one really blew me because the effect was big i.e. there was no ways for me to tell whether it was one or really 2 poles.

The shadow on all cases appeared was very hard to differentiate from the real one.

(The whole thing is new to me because I never went outside without glasses or lenses.)

Is this what all myop experience? Is this double vision or standard blur?

thanks
George

Please don't quit reading! People who read are nearly extinct as it is -- but have you taken a close look at the non-reading majority? I'd rather be extinct than belong to the species...

Reading is not the root of the evil. People who don't read tend to have rigid, calcified minds embedded with cheap plaster ideas that clog their brain arteries, precluding any flow of thought. As for their emotions, I don't even care to get a clue.

> I want to
>be able to sit quietly with my own thoughts, with out feeling the panic,

Oh yes, it's scary -- most of it. Life, that is. When I started VT -- and I started by trying to analyze the emotional aspects of myopia, because I believe myopia can be very well understood as an emotional response gone physical -- it soon escalated to the point where for about a week, whenever I was alone, with nobody looking, I would start crying -- all those old, ancient tears I should have shed many years ago but didn't. And then one night I had a dream that seemed incredibly meaningful... one of those you maybe get two or three times in a lifetime... and someone in the dream said (in a rather high-flown style probably characteristic of significant dreams): "Face your fear. Look it in the eye. Make it blink." I was rather shaken because I immediately knew it was exactly what I would have to

do: reclaim my long-lost courage.

Elena

Betty,
Thanks for the information on aspartame. I don't use it, nor do I allow my children to have it. We sometimes feel strange insisting on real sugar :) Years ago, when aspartame was first introduced, I found that it gave me headaches. Being slightly skeptical of artificial food, I had no trouble living without it. I am not surprised to hear it is damaging.

Elena!
That is GREAT. Shorter eyeballs - I am very encouraged. I am convinced I have reached the limits of what I can do with just lense accomodation (I tried an Accomotrac unit here, and was underwhelmed). I, too, found that my accuity dropped drastically in the examination environment. I heard the lecture about the plus lenses, about "old" eyes (presbyopia) and how I would have to settle for less if I reduced my prescription.:P I also got the speech about not driving under corrected. I was treated as if I was blind! I don't think anyone there realizes how much I CAN see - I just have trouble with Block Letters at 20 feet :D

Thank you for your post. I am feeling very inspired!

I am curious about this, too. When I look at the crescent moon, I sometimes see 4 or 6 little semi circles arranged in what appears to be a little pine tree. I can cover one eye, but still see multiple images. Sometimes the moon stays together pretty well, sometimes not. Is it related to night vision?

Dear Mary: Be careful to avoid aspartame now that it is in 7000 products. Its in your bakery in cakes and pies, antibiotics, over the counter products like Nyquil and Metamucil, breath mints and restaurant food. And now that the patent has expired you find it marketed by its generic name aspartame, NutraSweet, Equal Measure, Equal, Spoonful and many other names.

The headaches are from the wood alcohol (methanol) that converts to formaldehyde and formic acid in the retina, and in the body. Headaches have the highest number of complaints on the FDA report which list 92 documented symptoms from coma to death.

I also use bilberry and believe it is a successful nutrient to the eye. We need all the help we can get. Now that the Fatal Drugs Allowed folks have approved Olestra, artificial fat, we are presented with a chemical that Science News, January 27, 1996, says "helps carry away fat soluble vitamins such as A, D, E and K." The article continues "the fake fat would also sweep out of the body nutrients called carotenoids, the yellow orange or red pigments found in many fruits and vegetables. There are about 500 nutrients in the carotenoid family -- too many to add back to a bag of chips. Yet some carotenoids are thought to shield people against a wide range of diseases, including an eye condition and prostate cancer."

According to the article: "Stampfer, also at the Harvard School of Public Health, turned his attention first to age-related macular degeneration, a disorder that causes blurry vision and blindness. In 1994, a Boston team provided compelling evidence that two carotenoids, lutein and zeaxanthin, help prevent this devastating disorder (SN:11/12/94). "

"A 10 percent drop in concentrations of lutein and zeaxanthin would result in 390 to 800 additional cases of macular degeneration per year in the United States, Stampfer estimates."

Sometimes I wonder if the FDA has declared war on the American people. They approve poisons like aspartame that blind, and then approve a product that leeches out the betacarotene and vitamins that help fight the diseases their poisons give us. One more to avoid, folks!

Regards,
Betty

A bit surprised here Elena. Overall I enjoyed reading about your wonderful positive progress. But.. I must beg to differ on your views above even though they have nothing to do with the themes of the ISEE group. Sounds like you are making a really hard and generalized judgement on people who don't read. Such generalizations are generally none conducive to positive growth for anyone. I must tell you that I know a number of people who don't read or even know how to read and they are the purest of hearts. These are farmers who work hard from sun-up to sun-down and obtain their wisdom directly from the land, from mother earth and from family life. In fact their lives are now being made miserable by those who "read" and "write" long and pedantic laws which tend to confuse and demoralize people. Elena I do hope that you do get a clue, and that you did not mean so much of what you said. Clues often do come from other places than from the "written word", and more often than not, "cheap and

calcified" excrement is found in the form of writting.

Plus lenses vs. no lenses question

- *Subject:* Plus lenses vs. no lenses question
 - *From:* John Stabile <d018133c@dcfreenet.seflin.lib.fl.us>
 - *Date:* Tue, 13 Feb 1996 16:02:59 -0500 (EST)
-

Greetings all--I am new to this idea and would appreciate some info about the use of these lenses. If I understand correctly what I have read, when doing some eye exercises it is OK to not use glasses at all in order for the eyes to strengthen themselves quicker. So I am trying the exercises without glasses. I am also trying to go without glasses around the house. Would it be better to use the plus lenses in either of these cases?

I also plan to start using an old pair of contact lenses that are much weaker than my current lenses to force my eyes to work harder. Is this advisable?

Thanks for any support/advice you can provide.

If you don't recycle, you're throwing it all away.

Blur and Double Vision

- *Subject:* Blur and Double Vision
 - *From:* "Linda" <llee@comox.island.net>
 - *Date:* Tue, 13 Feb 1996 18:07:05
-

Recently, George and Mary wrote about double vision and blur. I have also wondered about this. Sometimes when my vision is very clear, i can see two overhead power lines where i know there is just one. They are both very distinct, although i can usually tell which is the 'real' one.

My own explanation for this is that there are two aspects of vision (well, at least two, but bear with me here). On the one hand i have that accomodation thing going on, where my ciliary muscles are learning to control my lense to adjust to various levels of clarity. Then i have a vergence thing happening where some other muscles are trying to focus on just one point in space. Does this make any sense? It does to me.

yes. but if you have any astigmatism it may have changed.

Was it an Inca or a Maya king (I forget which) who had the single largest
one-time ritualistic human sacrifice in history performed in celebration of
his birthday? (80,000 men killed by ripping their hearts out alive?) And
weren't the Nazis even more amazing at engineering than both of the above?
Anyway, that's quite beside the point... or is it?

What's gotten into me really? Getting into arguments left and right --

after all those conflict-free years when I just took care to be oh so sweet -- lest I accidentally offend someone by having an opinion... Well -- although I'm sorry I provoked and am now expanding this digression, it's not totally beside the point: it has something to do with my vision, it's yet another sign that I'm getting back to normal. I used to firmly stand my ground -- and see clearly; then I gave up in every possible sense -- and forfeited my clarity. I had to dislocate my brain and teach it to perform all kinds of ideologically acceptable doublethink... in case you read that book... at a price. And guys -- I had to stop having opinions in order to become a socially acceptable female, among other things. Well -- if you need approval really bad you learn how to shut up, and shutting up and listening becomes your second nature. And of course it pays -- you become so very popular... and so very myopic, because whatever it is that you told to shut up is YOU. You tell it to shut up and it just turns away and doesn't want to see the outcome of being thrown out of the picture. You become so nice and submissive and low-key... a real lady... but the real you doesn't care to look at the results. The real you takes 8 diopters of separation from what has happened.

Please understand me right: I had modern_urban_anticulture in mind -- I have nothing against those pure-hearted farmers, although I don't believe that being undereducated is in itself a warranty of a pure heart. I didn't mean to speak against the underprivileged -- because having no access to either monetary or cultural resources is being underprivileged, and who has the nerve to blame someone for not having what he can't have? Monetarily speaking, I'm rather underprivileged myself (and also knew real poverty, not the milder, state-buffered American variety). But I do have something against people who are stupid and proud of it, ignorant and proud of it, intellectually sterile and proud of it. And this particular type thrives on non-reading. Of course I didn't even dream of including those horrendous artifacts of legalese mentioned by Mario into what I mean by reading. I meant reading as communication with generations and generations of thinkers all across human history, something that turns you into a civilized human being... And "civilized" has little to do with engineering achievements OR being close to mother nature. My cat is quite close to mother nature. Whose sig. at one point was "civilization is about not killing people?" -- a member of the group used to sign his posts like that? I totally agree -- that's part of it. I also don't include into the notions of civilization and culture things like technoalienation, or cheating people out of human ways to sustain existence, or that artificially programmed, robot-like behavior they hail as "professional attitude." I also happen to believe that the best of constitutions lack a very important clause pertaining to human rights: a clause that would ensure that no man shall be wrongfully condemned to ignorance and stupidity. So someone who's trying to persuade me that being ignorant is a birthright to be defended is simply a member of a political party I don't support. Even though the party I do support, the party for healthy, happy, and intellectually fulfilled life for all, doesn't exist.

And now if the majority feels I absolutely, positively must shut up I'll just take my opinions elsewhere. No more shutting up for me, that's for sure.

Elena

"A life unexamined should be terminated with extreme prejudice." (Someone else's .sig I'm borrowing for the occasion.)

"When I hear the word 'culture' I grab my remote control." (Goebbels, Hitler's minister of propaganda -- a little modernized.)

Re: Blur vs. double vision

- *Subject:* Re: Blur vs. double vision
 - *From:* Alex Eulenberg <aeulenbe@indiana.edu>
 - *Date:* Tue, 13 Feb 1996 23:05:05 -0500 (EST)
-

It seems a lot of us have discovered monocular diplopia or polyopia (double or multiple images seen with an individual eye). The ghost images we are seeing are quite often encountered by persons improving their vision. I get them too. It seems as if we're trading blur for double images. As Vic pointed out, this has something to do with astigmatism. I'm not sure about the optics of it all, but a few articles have appeared on the subject of monocular polyopia which occurs after near work, or after directing the eyes at odd angles for prolonged periods of time. In many cases a change can be noticed in the cornea. Some refer to the extraocular muscles as a possible cause, others to the eyelids. See I_SEE member Rich McCollim's article at the I_SEE library:

http://silver.ucs.indiana.edu/~aeulenbe/i_see.html

His article is called "How NOT to cure myopia: the incyclorotator"

Rich describes his experience wearing a mirror device that made the eyes rotate inwards along the axis of vision, or "incyclorotate" in order to produce a clear image. This resulted in monocular diplopia. Rich concluded that the change was in the lens, caused ultimately by the abnormal tension of the extraocular muscles.

Goss & Criswell's subject (see below) "preferred to watch television while reclined in a supine position with his legs pointing toward the television set and his line of sight passing just above the tips of his toes. Viewing times as brief as five minutes could induce the effect." The authors conclude that the lids were the source of the problem, but I think it could as well have been the extraocular muscles. Goss & Criswell published photographs showing how the cornea became distorted after television viewing.

William Bates, incidentally, believed that multiple images were "tricks of

the mind only"; he did not know of any error of refraction that could account for the kind of monocular polyopia he encountered with his patients. In /Better Eyesight Without Glasses/ he describes a man who saw double letters with his right eye, and multiple images of a pin with his left (pp. 114-115). He later comments:

:After a few attempts most people easily learn to produce polyopia at
:will. Staring or squinting, if the strain is great enough, will usually
:make one see double. By looking above a light or a letter and trying to
:see it as well as when it was directly regarded, one can produce an
:illusion of several lights or letters, arranged vertically. If the strain
:is great enough, there may be as many as a dozen of them. By looking to
:the side of the light or letter, or looking away obliquely at any angle,
:the images can be made to arrange themselves horizontally, or obliquely
:at any angle. (p. 119)

What to do about them? I have found that, as usual, muscular relaxation in the area of the eyes usually results in improvement. I have found palming to be especially beneficila. Conversely, I have found that any eye exercise done while fatigued -- mentally or physically -- tends to aggravate the condition.

John and all

The purpose of any plus lenses, or a reduction in power of the myopic lenses, is to reduce the requirements of focusing at the near point area you are attending. If you are myopic, your eyes already have, shall we say "plus built in," therefore you would, by definition, not have to focus very much for near. If you are very nearsighted, you may need to wear a bit of power to enable you to see at the desired distance.....in no case would it be advisable to wear the distance power for your reading area. One thing that you said bothers me.....that you were going to wear an old pair of contact lenses...if the lenses are soft, they have the very strong potential to cause eye infections and very bad consequences, since bacterial, etc. would have grown on them. If the lenses are the firm variety they could have warped and, thus could warp your corneas. If the surface was not pristine, wearing an old pair of contact lenses could affect the oxygen that reaches your corneas. In any case, I would go back to your practitioner for consultation and evaluation of the lenses that you plan to wear. Contact lenses can be the cause of medical problems ranging from mild irritation to blindness....do not fool yourself into trouble !!!

Plus Lenses aren't enough!

- *Subject:* Plus Lenses aren't enough!
 - *From:* Alex Eulenberg <aeulenbe@ezinfo.ucs.indiana.edu>
 - *Date:* Wed, 14 Feb 1996 22:17:00 -0500
-

Here are some snippets from article from the Optical Journal and Review of March 12, 1914. I just posted it to sci.med.vision. The main point of the article is that plus lenses in themselves won't necessarily relax your accommodation. You need to practice the art of negative accommodation.

A note for the newcomers: "cycloplegics" are the drops that eye doctors put in your eyes and make you unable focus up close during (and unfortunately after) an eye exam. It used to be only MD's could use them, but not optometrists are using them too.

* * *

POSSIBILITIES OF NEGATIVE ACCOMMODATION
By Eugene E. Heard, Pittsburgh, Pa.

I believe the value of practising voluntary relaxation is not appreciated at the present time. ...

The countless thousands who toil in the offices of our large cities from morning until night, subject their eyes to a tax such as their forebears never knew, and when we remember that the eyes are capable of only three and a half hours of continuous application without strain, one can easily see why these people should be taught one of their most priceless means of relief from strain due to keeping their eyes too long in exact focus.

Few, indeed, realize that after a little practise they have the power of relaxing the ciliaries more completely and naturally than can be done by cycloplegics, and accomplishing it more readily

I beg to argue that this so-called fact, the accommodation being relaxed

in the normal eye for infinity, is mere theory, as there can be no proof when in any particular person the ciliaries are absolutely relaxed ...

Relaxation is not proven by the inability to read when under the influence of a cycloplegic ... for these muscles are very likely to have been paralyzed in exactly the same cramped position in which they were, at the moment of application of the drug. In other words, I say that paralyzation is not necessarily relaxation; they may be unable to accommodate, but still be cramped. This is probably what happens when drugs are used, for in no other way, as reasonable, can we optometrists account for the constantly increasing number of cases coming to us, having failed to get relief from oculists who had put them under these various cycloplegics, the cramp not being revealed by their method, as it was not relaxed, but locked up. ...

This voluntary relaxation which I advocate is easy to learn when constantly practised for a few weeks. Each effort renders the next a little more effective. It can be quickly practised a few times at odd moments while waiting for a street car, waiting in a restaurant and between the acts at a theatre. ...

I can hear my critics say, "more plus--more plus," but I was on the firing line for "plus" lenses when there were so few there that I felt lonely, and after many years of wearing an excess plus and also after having prescribed for many thousand cases, have found that all of the cramp cannot be unlocked that way, and that the brain must be taught to help out the accommodative as well as the extrinsic muscles, in their effort to relax with the aid of proper lenses ...

The writer has had very encouraging results along this line, having succeeded in getting nervous cases to accept much more plus than was at all possible to tolerate by the usual methods, besides teaching them a resource for immediate rest that they did not know they possessed.

*

*

*

Unfortunately, the author does not elaborate upon his method for teaching voluntary relaxation of the accommodative muscles, but it is obvious that it does not require any fancy electronic biofeedback equipment, since it can be "practised at odd moments" throughout the day. Bates's popular book didn't come out for another 6 years -- 1920 -- so it is unlikely that Heard had anything like the Bates method in mind. Moreover, it is Bates always insisted that relief from unconscious strain can never come about by voluntary effort to do so -- only through imagination and central fixation.

I don't know if we ever answered this question completely. In any case, someone brought it up again on sci.med.vision under the subject heading of "Eye vitamins", and I posted the following reply, which I now share with I_SEE:

Todd Wallace wrote:

>I have heard that there is a combination of vitamins useful for treating
>or preventing eye disorders. Does anyone know what these vitamins are?

Richard C. Hom, O.D. <rchom@ix.netcom.com> wrote:

>The most eye disorder and the most efficacious use of nutritional
>therapy is in the area of macular disorders. There are several kinds of
>preparations. The most common are Ocuville and I-Cap. They're expensive
>and I've heard of patients comparing the ingredients of these two with
>other available preparations and using the substitutes.

But Dr. Hom, what are the vitamins? Won't you tell us? Oh well, fortunately, Todd, I have a copy of "129 Amazing Medical Secrets Your Doctor Won't Tell You" by Julian Whitaker, M.D. I got it as a freebie when trying out his newsletter.

Dr. Whitaker's secret #131 (131? Well, you can't judge a book by its cover!! So that's why he was giving the book away...) is that the following nutritional supplements, taken daily, "help prevent cataracts, macular degeneration, glaucoma, and dry eye":

Riboflavin	Cysteine
Flavonoids	Taurine
Vitamin A	Beta-carotene
Vitamin C	

His secret #132 is that anthocyanosides, "a form of flavonoids found in blueberries, grapes, and other fruits and vegetables," improve vision.

Secret #134 is that ginkgo biloba (an herb) improves circulation to the eyes.

Bilberry, which contains anthocyanosides among other things, is said everywhere to be good for the eyes. I have a cheap brand of bilberry complex containing bilberry standardized extract ("contans 25% proanthocyanidins"), 80 mg; beta-carotene, 6 mg (200% US RDA); Riboflavin, 10 mg (580% US RDA), carrot powder containing an addition 1-2 mg beta-carotene, 300mg, citrus bioflavonoids, 100mg.

The herb eyebright is supposed to be good for vision. I've seen it packaged in various "eye" formulas. It's also available in bulk as a loose tea.

Actually, I've heard that just about every vitamin under the sun is good for your eyes. Considering that vision is muscular, neural, and dermal (yes there are skin cells in your eyes), this is not surprising. Your eyes have lots of different parts and they need lots of nourishment!

Interestingly, ginkgo is also often recommended for tinnitus for similar reasons, although results appear to be very mixed, perhaps because causes of tinnitus are many and varied. (see alt.support.tinnitus).

p.s. bilberry seems very difficult to obtain here in GB.
have all you yanks cornered the market? :-))

John,

exercises should be performed with no glasses on. From the previous discussion on plus lenses, their use depends on how myopic you are.

As to using and old pair of contact lenses, well I wouldn't do it. a dirty lense might give you a nasty infection. ALWAYS use fresh ones (disposables are good and cheap). I personally gave up contacts for glasses about a month ago when I started my VT program and I find it much more practical to take them off.

george

From: owner-i_see@indiana.edu on behalf of John Stabile

To: i_see@indiana.edu
Subject: Plus lenses vs. no lenses question

Greetings all--I am new to this idea and woud appreciate some info about the use of these lenses. If I understand correctly what I have read, when doing some eye exercises it is OK to not use glasses at all in order for the eyes to strengthen themselves quicker. So I am trying the exercises without glasses. I am also trying to go without glasses around the house. Would it be better to use the plus lenses in either of these cases?

I also plan to start using an old pair of contact lenses that are much weaker than my current lenses to force my eyes to work harder. Is this advisable?

Thanks for any support/advice you can provide.

If you don't recycle, you're throwing it all away.

<snip>

Ocuvite I personally vote out for the following reasons:

It has 40mg of zinc, which is good, and only insufficient amounts of A, C, E, and selenium (forget the RDAs -- to say they're on the conservative side is to say nothing). But you can't double or triple the benefits by taking 2 or 3 Ocuvites because zinc is toxic in the amounts exceeding 65 mg. Plus Ocuvite contains copper, and although its function in the eyes is important, its use as a supplement is controvesial, especially when combined with ascorbates. Together they form highly invasive superoxides that yield an 85% increase in random DNA damage. It is believed that copper should only be obtained through dietary sources. So I think it's more prudent to buy zinc separately (a lot cheaper, too), and get other goodies from other sources. Another trace mineral to avoid in supplements if you take high doses of C is iron, for the same reason as copper. (Disclaimer: everybody knows I'm not a doctor, right?)

Twinlab makes a good supplement for the eyes but I forget the name. (You'll recognize it if you see it -- there's this pyramid with an eye on the box, like on a dollar bill.) But there's copper in there, too. I don't know what gives.

P.S. I've changed my address line -- Alex I'm sorry you had to forward my mail (a lot _was_ coming through so I didn't know there was a problem). If anyone else has had trouble with my e-mail address, please try again.

I did a small exercise today: closing one eye at a time and looking at the distant object. With each eye I saw two objects (the real and its shadow), both with the same `_sharpness_` and the `_same_` distance apart. BTW, I have one dioptre difference between my eyes.

I don't think it is something to do with the eyes because of the above result. I do think it is something with the mind interpreting the input from the eyes.

Is this a myopia blur or something else?

george

Could you specify what you mean by "also"? That you've caught me lying before, or someone else in the group, or everybody else in the group? Personally, I don't remember hanging out in W.Australia (much as I'd love to) and being caught red-handed by Mr. Malpractice.

> Why could you not blink. I would bet money
>that you could.

>

Please make that a money order, not a personal check. Lack of trust is mutual.

Now if what I stated about blinking needs explaining, here goes. You're asked to press your forehead against this concaved device so the windows (small! giving only a narrow view in only one exact position! and excluding all use of your peripheral vision skills!) you're looking through are directly in front of your eyes. In this position, my eyelashes are pressed tight against the glass. In order to blink, I have to move my head backward, but then my forehead is no longer positioned where it's supposed to be, ditto my eyes. While I move my head back to blink and then forth to resume the position, the doc has already changed the letters I'm looking at. Granted, part of perfect vision is rapid focusing; in my case, however, it tends to be slow -- I need a few seconds, my focusing is a newly learned motor skill (intimately connected with precise blinking as I mentioned), not a "natural" that comes with already good vision. It's like playing the

piano... you can play a fast piece when you're proficient, not when you're just learning. And you probably can play when you're handcuffed if you're Franz Liszt... Well, I'm not, at least not yet. Remove the "handcuffs" from my eyelashes, give me the few extra seconds I need, light the freaking office properly, and see what happens.

I recently had an eye test as part of a routine work medical. They asked me to look through a device with a name like "Keystone" something or other. I was afraid that it would not allow me to blink, but I was please to find it was quite possible. (That was the only good news though: they said I had "failed" the VDU test, which means I "need" glasses to use a VDU, and I need to go for a further more detailed test. Since I already wear + 1.0 reading glasses (drug store variety) for VDU work and most reading, this came as no surprise, but it still hits you when it happens. Let's hope I can find some bilberry soon..)

Well, Peter, I have often felt that there was something about the eye exam situation that causes me not to blink. I felt that way for many years, until I just decided that it was wrong, and started paying attention to what was going on. I still don't understand it, but it is real, for me. One thing that I did notice was that at some point durring the exam, someone will tell me not to blink, but they never follow it up with, "OK, you can blink now." So what is the poor, too willing to cooperate, patient to do? Try not to blink until he/she leaves the office?

Do you, or one of your assistants, ever tell your patients not to blink?

On Friday, 9 Feb 1996, Dr. J. Mason Hurt wrote:

The Precise Cornea Molding procedure was developed separate and apart from Orthokeratology, even though it does share some similarities. When it became known what I was doing, I was sought out by Dr. Newt Wesley, the founder of the National Eye Research Foundation ("NERF"), and the others. They came to Memphis to see why I could do things that the other doctors practicing Orthokeratology could not. As a consequence, I was asked to join the National Eye Research Foundation to share with those who do Orthokeratology what I had discovered separate and apart from them. Consequently I spent a year traveling all over the country for NERF lecturing on corneal molding. Many of my ideas therefore were incorporated by many of those who do Orthokeratology. When I started working with NERF there was just a handful of doctors who were actually pursuing Orthokeratology. Our meetings would generate at first only a handful of people, but over the months grew to be many. At my last speaking opportunity there were over 300 people.

PCM does several things that Orthokeratology to date has not been able to do. Besides the elimination of greater amounts of nearsightedness and astigmatism, PCM also eliminates farsightedness and builds in a bifocal for the presbyopes and pseudo aphakes. As a past lecturer for NERF I was granted a fellow status with them, so I am more than aware of what information NERF provides both to the public and to the practitioners. Even though Mr. Paul M. Planer has a good intent, he still speaks about something of which he knows nothing. PCM is to Orthokeratology as a Ferrari is to a Model T. Granted, both are modes of transportation, but one gets you there with much greater efficiency. Since PCM is proprietary, only those physicians trained in PCM know of PCM. So it is possible for those who don't know PCM to consider it as Ortho-K. All statements made by those individuals would be fallacious since they speak of things they know not.

Most of the people who do Orthokeratology and do it with great frequency know the struggle they have had in getting respect in their profession because so many doctors thought this type of procedure, being routine, needed no special skills or understandings. We have demonstrated with PCM that it does take considerable skill, considerable understandings and specialized instrumentation to accomplish our task, when in Orthokeratology those were not utilized nor were they encouraged. As one who has seen the development of PCM I have had the opportunity to share my knowledge with hundreds of doctors now who do Orthokeratology, it is with confidence I can state that these two procedures are quite different; the way the cornea is reshaped is quite different; and the instrumentation used and how it is used is quite different.

PCM offers benefits to those individuals even who have had RK surgery,

ALK surgery, and often even those who have had PRK surgery. PCM is the therapeutic procedure of the 21st century.

Sincerely,
J. Mason Hurt, O.D.

When I did my test today with my optometrist, he didn't say anything about blinking/not blinking.

So I did blink whenever I needed to and the equipment he was using was not interfering with the process.

I think the equipment used by optometrist is not the same all over the world and that might explain why Elena could not blink.

Well, Peter, I have often felt that there was something about the eye exam situation that causes me not to blink. I felt that way for many years, until I just decided that it was wrong, and started paying attention to what was going on. I still don't understand it, but it is real, for me. One thing that I did notice was that at some point durring the exam, someone will tell me not to blink, but they never follow it up with, "OK, you can blink now." So what is the poor, too willing to cooperate, patient to do? Try not to blink until he/she leaves the office?

Do you, or one of your assistants, ever tell your patients not to blink?

Dennis Yelle

I think you should be able to find Bilberry in tablet form at the pharmacy or health shop.

The ones I have are made by Blackmores and I think their products are available in the UK because the label on the bottle has the address of the company in Australia (where I am) and at the end has the following which might make sense to you in the UK:

Colnbrook Bucks
United Kingdom

I hope you could decipher the above.

George

I recently had an eye test as part of a routine work medical. They asked me to look through a device with a name like "Keystone" something or other. I was afraid that it would not allow me to blink, but I was please to find it was quite possible. (That was the only good news though: they said I had "failed" the VDU test, which means I "need" glasses to use a VDU, and I need to go for a further more detailed test. Since I already wear + 1.0 reading glasses (drug store variety) for VDU work and most reading, this came as no surprise, but it still hits you when it happens. Let's hope I can find some bilberry soon..)

Hi Riaz,

Well I'm not doing anything unusual. I'm approaching Myopia as if I have a broken leg. In other words, at one point in time (when I was 15) I got myopia and I started using relying on my glasses.

So whatever I'm doing I keep in mind that I will get better because what happened to me was an accident. I understand that the cause might be a combination of things: fatigue at school, nutrition and possibly lengthening of the eyeball...

I followed the exercises metioned in a number of books on VT based on the Bates method, namely:

- 1- the neck and shoulders muscles
- 2- eyeball muscles
- 3- accomodation
- 4- eyechart reading
- 5- sunning
- 6- swinging ball
- 7- reverse newspaper reading

and lots of eye relaxation. All of the above is described in the FAQ available at the I SEE web site.

Also, I rarely use my glasses: during the day I drive and play tennis without them.

To that I also take Bilberry and Eyebright tablets and I recently started taking protein suplement.

That's it.

Hope this helps.

George

Thats great to hear. Can you tell me what kind of eye exercises you've been doing? I tried to do some excersises for a few months but failed to see any real progress, I was probably doing them incorecctly. :)
Thanks in advance.

Regards,

Riaz Oosman

Ask, "May I blink now?" :-)

Joking aside, blinking often helps clear the view, but that's an auxiliary technique. It relieves momentary fatigue and helps renew the tear layer, but it doesn't help towards changing the underlying structural parameters of the eye. I wonder, though, if it could be argued that blinking has something of a carrot-and-stick element in it: see clearly for a while, fade, then try "pushing" with the extraocular muscles, forget the goal, and blink again to remember. My opinion is this would be overstretching it.

Stefan

> are directly in front of your eyes. In this position, my eyelashes are
```

> pressed tight against the glass. In order to blink, I have to move my head
> backward, but then my forehead is no longer positioned where it's supposed
> to be, ditto my eyes.

In the correct position you can blink. Next time don't press against the
instrtment - you will only smear the lenses and slow the process. You
could say something to the practitioner - you are paying for their time
and from what I hear in your country, which I have visited, paying dearly.

I am I think able to question unqualified statements. I have been
caught out a couple of times on this group before ALSO.

Best wishes,

Peter Locher

My Dear William (and others),

What can I say?! It seems that, on this mailing list, there are more sceptics than 'believers'.

I don't mind people says well let's see what the result is going to be next month, but to actually find absurd reasons for the improvement (i.e. "that was your functional myopia..." or "your .50 to .75 change may be just error of refraction, which is in the range of that found on a day to day basis...") is quite unbelievable.

Why is that for the first time since I got myopia I actually made some improvement? Did I pick my good day to have my eyes checked? I don't think so.

Why is that my optometrist, who is supposed to discourage me and find some nonsense to throw at me, did not do so?

Why is it that you do say: "Any further 'reduction' *would* be unusual, to say the least"? If that's what you think, why are you (and others) on this mailing list? I really don't understand it. Are you a pissed-off myopic who's not getting results? or an optometrist having a laugh at what we talk about around here?

I personally don't believe my personal case is genetic, structural... I was not born with myopia, and I did not have a physical or emotional accidents/problems that might account for my condition. I believe it is a combination of: fatigue, straining... (observed by Bates while studying school kids) and nutrition.

That's how I'm tackling the problem: I have a broken leg and I need to exercise it, look after it and feed it. How long it will take to heel? I don't know but I do know that it will get better.

I don't know what the result will be next month. and to tell you the truth I expected the decrease in myopia that I had to occur in 6 months not 4 weeks.

Finally, PolySoft is not in the contact lenses business. It's a consulting and software development company that I co-founded few years ago.

Talk to you next month.

george

From: William Stacy
Sent: Tuesday, 20 February, 1996 2:01
To: George Tohme
Subject: Fwd: Re: To the sceptics: Results of the first month of VT (fwd)

After I sent a less than enthusiastic comment on your post which Alex forwarded to me, in which I challenged your ability to make significant further reductions via VT, he sent me this:

---- Begin Forwarded Message

On Sun, 18 Feb 1996, William Stacy wrote:

>
> (I'm gonna keep your note on my desk to remind me to check back in a
> month, so tell George to keep up the good work for at least another
> month, OK? The pressure's on now!)
>

Why don't you write him NOW and see if he'll let you talk to his optometrist? You'll get a better idea of how "typical" the improvement was.

--Alex

End Forwarded message

My position is that your .50 to .75 change may be just error of refraction, which is in the range of that found on a day to day basis. Any further 'reduction' *would* be unusual, to say the least.

I would love to hear further specifics, especially in another month or so, so keep it up and let me know.

Bill

BTW, what is polysoft? Are you in the industry? It sounds like a contact lens term.

George, don't pay any attention to dr. Stacy. He's just a fugitive from sci.med.vision who comes over here to badger Alex because things are so boring over there. Their profession has utterly failed the unnecessarily huge numbers of myopes in this country, and they can't stand to admit that others may have a way of halting and reversing myopia. Such an admission would expose the utter failure that is their life's work. Keep up the good work and keep us posted on your excellent progress.

Just for the record, Dr. Bill Stacy <ws@ix.netcom.com> unsubscribed from I SEE over a month ago. I was the one who forwarded him George's message about his optometrist-verified vision improvement, and I was the one who told Dr. Stacy to ask George for more details. Specifically, I asked him to contact his optometrist for verification. Remember also that George's post was titled "to the sceptics". Dr. Stacy had offered a cash reward for clinically verified myopia improvement a while back, and since he had unsubscribed, I didn't want him to miss this one.

Yes, I told you that this change could be the elimination of your functional myopia. And yes, I am a pissed-off myope who's not getting results. No, I don't want to discourage you. Keep doing what you are doing. 'Cause nothing is worse than not having faith. Yes, I have always been and continue to be in FAVOR of plus lenses (although never worn plus lenses proper, just less minus). But I view plus lenses as a preventive device, not as a cure. Yes, I have tried hard to reduce my myopia and God only knows how hard I've tried. I can tell you, my vision fluctuates daily within 1.00 D, and initially, after I started "intensified VT" (i.e. I quit using weaker glasses for reading and went on with no glasses at all, that is increased plus) I had that surge in acuity. My faith and positive attitude keeps from deteriorating. But there is no stable progress and I've been doing this for six months. Antonia Orfield is probably the example to draw inspiration

from, but to match her one will have to take seven years off. Sorry, not in the 1990s. I feel the most happy when I see well in the distance and I can't do this if I am wearing 20/40 glasses. I am currently reconstructing every single bit of my myopic life, analyzing the reasons for increases in myopia, and devising plans to fight them in the future. And I shall probably up my glasses for the last time before I undergo PRK. But I admit, I am utterly reluctant to do it and am still wavering. But I have a parallel in my recent past where I increased power and had the most rewarding days EVER following years of foggy semi-existence. My current slump into myopia is related to an extraneous shock, which, regretfully, I was not mature enough to handle. As soon as I convince myself that I am able to handle higher power ('cause for a plus enthusiast there is a lot of unease of going counter my beliefs), I'll up my glasses.

Please let me know how you are faring eyewise in a month's time. Several months ago somebody with an address <JohnRICH95@aol.com> was claiming intial success. I tried to track him down two weeks ago but apparently he's changed addresses (Yes, I tried with 96). If this person is still on the list, please respond. Again, I don't want to discourage you, George, but I side with William that any further decreases will be unusual.

Best wishes,

Stefan

>Yes, I
>have tried hard to reduce my myopia and God only knows how hard I've tried.

Stefan,

this might be the root of the evil. I've "tried hard" for 25 years and my vision kept getting worse -- not "fluctuating" but "worse," never moving in any direction other than that, not even for a second. And "plus" in the sense of "less minus" is something I've always worn. Not enough. I now own a pair of plus glasses in the sense of "real plus," too (+1,5; I'm coming from -8), and I don't see that they make a lot of difference. It was cool to get my first right-through-the-plus clear flash -- very impressive -- but any and all effects I get from plus lenses are so transitory that for me, it's not worth it. Probably too late. But other methods I use do work. They all have to do with relaxing, not "going for it" or demanding it. Finding your personal way to stop_trying_hard is of paramount importance. Strain, remember? Frustration over expectations unfulfilled? That's her majesty myopia herself. When you try hard you just serve her, is all.

I hope it sounds like I intend it to -- a hint you might find helpful, not criticism of your approach.

Elena

Plus lenses, Dr. Harris attests, when worn by non-myopes, can create more farsightedness -- the flip side of "plus lenses for myopia." However, both behavioral optometrist Harris and traditional "skeptical" optometrist Bill Stacy agree that hyperopia never becomes as "pathological" as myopia often does.

The following two posts were taken from the sci.med.vision newsgroup.

>Well that's news to me. Every moderate to high hyperope (~ +2 D. and
>up) I ever ran into was about as stable as the Rock of Gibraltar.

>
>Progressive hyperopia???

Yes... This is the development of adverse hyperopia. The cause most often is as a secondary iatrogenic disease caused by the overzealous

prescribing of plus.

I know you and others will say if a good cycloplegic were done.... and things likelatent hyperopia.....

I was a subject in a longitudinal study for 5 years as a child. All this plus, A-Scans, Purkinje images measures of radius of curvature of front cornea, rear cornea, front lens, rear lens, anthropomorphic measures, IOP, wet and dry refractions, full 21 point analytical and more were done every 6 months for 5 years. I have the data on myself. At no point did I ever show hyperopia more than +1.00 to +1.25.

After the study at age 15 I started wearing single vision plus to play chess and this was upped and upped. NOTE: I was measured with a 14 to 1 ACA ratio. 16 eso at near through whatever distance lens of the time and 2 eso with +1.00 add over that. The standard theory was "push plus". This was done and I ended up at one point wearing +2.25 OD/ +2.50 OS with a +1.50 add for 10 years. I measured well up in +3.00 range when my father (my optometrist then) was done with me.

There was no latent hyperopia over the +1.00. The additional amounts were built up slowly over time in response to my optometric care.

Once I did VT 13 years ago I now wear just some plus for near and nothing for distance. My subjective now is +1.25 OU which I choose not to wear and do great. In fact I now see better than ever.

I hope this explains a bit a very big subject which I am fully aware of there will be little agreement on from the conventional eyecare establishment. Please give me some other alternative to understand the above findings over time. I also have basic optometric data on me from the age of 6 months.

LOTS snipped.....

>Very interesting data. Very interesting study (Was it published?).
>

Yes in several places. Chief investigator was Bill Ludlum. The study was so large that it was reported in sections. Most appeared in the academy journal and others in the Journal of the AOA. I don't have the references handy but could look them up if you wish. My case was lumped into the 500 or so subjects that were followed.

>I can believe you went from +1 to +2.5 or so (the 3 was likely
>over-zealous plus pushing), although I'd call it unusual, and certainly
>not like anything I've observed in young hyperopes over the years.
>
>It's still a far cry from the 8 or 10 D. or more of change in the
>progressive (aka pathologic) myopes.

I agree here fully. The +8 and +10 generally occur following a different mechanism. Most of which occurs very early, 18-36 months usually.

> I'd choose a different name, if
>you must have a name for such an occurrence, for consistency.
>
>Maybe "hyperopia creep"? "Far-sighted slip"?

We just use "adverse hyperopia". Hope that suffices.

I can really relate to what you are going through Stefan. You sound like one of my clients telling me their story. I humbly submit that you are at a very important step in the unfolding of your vision enhancement. If you will bear with me I will share some of my observations. Please understand that these are simply my perspectives that might be useful if not now in the future.

Improvement in vision first happens in our perceptions which is not measured in the eye but in our behavior as witnessed on the eye chart. To base success on the refractive changes as measured by the eye doctor is a myopic mind trap. The decreases in diopters is much slower than the

increases in perception as seen on the eye chart.
Visual acuity only improves as fast as one is ready to see. This means changing one's attitude or mind state first is a vital step in the _PROCESS_. It appears that you are experiencing anger and frustration at this delicate juncture of your vision improvement _journey_. Keep acknowledging these frustrations because it is the fuel that will fire up the later structural changes in your vision. My favorite saying is _Believing is Seeing_. I personally have witnessed -10.0's with astigmatism reverting to -5.00 without astigmatism as measured by an optometrist who didn't have access to the patients previous records. Also, I have a colleague who refracts -1.50 astigmatism on an auto refractor who is 48 years of age who has perfect 20/20 in spite of the physical eye still being astigmatically deformed.

Elena and I once again are in agreement. To improve vision is to be relaxed and calm. As a photogrpahic artist, when I look at a nature scene in a relaxed manner, I take a gorgeous photograph. When I try and take a good photograph and focus through my intellect, the picture is technically good but it lacks warmth and feeling. To see clearly is to feel. I offer you my support on your vision quest.

Hi Mario,

Thanks for bringing up this topic. I consider myself quite knowledgeable about laser refractive surgery (this term encompasses much more than the layman's idea of PRK - such as other types of laser (e.g. infrared, holmium, neodymium-YAG, solid state, besides the most popular fluore-argone excimer at 193 nm) and different techniques (PRK, LASIK). I've followed nearly every article since the pioneering work of Stephen Trokel in 1983, and "live-followed" the animal trials, the blind eye trials, the partially sighted eye trials, the normal eye trials (FDA phases I, IIa, IIb, and III), until the final approval of the FDA last October. I also follow the financial performance of all manufacturers of excimer laser systems as well as major surgery providers. I advise a small cap growth fund which recently bought shares of Laser Vision Centers International (OTC:LVCI) (a surgery provider) on my recommendation, but other than that I have no vested interest in the industry.

I'd love to jump into this topic. However, there is another thread currently "outstanding" towards which I feel equally compelled to contribute. I'll be giving preference to latter for the time being.

And another issue. I don't know if this list has something like a mission-statement, e.g. VT only. Refractive surgery is not VT. But neither is ortho-K. Also, VT does not end with refractive surgery, it is a life-long

process if one wants to keep their vision in shape. PRK just carves your glasses on your cornea. So, if there is really interest, I'll be happy to add my comments.

Stefan

Plus Glasses

- *Subject:* Plus Glasses
 - *From:* "Linda" <llee@comox.island.net>
 - *Date:* Thu, 22 Feb 1996 22:41:58
-

Inspired by all the recent chat about plus glasses, i spent the \$10 at the drug store and got me a pair of +1.5. I am still not clear what the benefit is supposed to be. I still have the same blur but now it is magnified. So, like, is this it?

Also it struck me as odd that nearsighted people have to sit in the doctors chair, look thru really expensive equipment, pondering that ever present question - "is this better ... (flip) ... or is this ...(flip)?, while far sighted people can go straight to the pharmacy and do that really tricky work themselves! And also, while i'm on a soap box, why did these glasses cost me \$10, while my myopic glasses cost about \$200?

Any thoughts?

Linda

what is the sunscreen for eyes that will not only counteract/balance the damage that would have been done to normally "susceptible" (to large amounts of eyestrain/eye-damage/tension) eyes, but then also counteract the damage done as a result of the greater susceptibility? Granted, it is possible to exist on this earth in a life that doesn't require lots of close work, but that isn't the life I want to live at the moment. It is possible, also to be born w/ a susceptibility so strong that no matter what spf you put on, you will get burned and/or it would be impractical to wear that degree of protection (limit your close work so severely). I need to see the chalkboard etc. I can't do that w/out glasses at the moment. I will continue to try too improve my eyesight through VT, but at the moment strain is being created b/c my eyes are fighting the perscription and maybe the perscription is pushing my eyes from their natural 20/20 state. It might be that my eyes (& I'm not alone), & I guess what I mean by "genetic myopia" is this, are going to be myopic even if I use them in the least

"susceptible eyes."

stressful way possible.

Anyways, I'm not giving up, just curious if there is this wall which cannot be crossed by some (possibly large # of) people.

Dr. Kaplan,

Thank you for the words of encouragement. I keep resisting to up my glasses. If only I knew for sure that permanent positive changes are possible, all the wait is worth it. Otherwise, for someone who has something of a hawk in oneself, the foggy anguish is too costly to bear.

Stefan

What Dr. Kaplan is saying is absolutely 100000% correct.

When I stopped wearing my contact 5 weeks ago, I looked around me and said to myself: "Oh boy, it's gonna be tough getting used to this blur". But I was willing to give it a shot.

Now, I only wear my glasses when I'm working on the computer and rarely while watching TV.

Blur is no longer an issue. I'm not even bothered by it. I look around me and enjoy what I'm seeing. And contrary to what people think when I say that I'm a -2.5,-3.00 myope, I SEE things. I drive my car during the day without glasses and it's absolutely safe (in my case). My wife I went for a walk on the beach yesterday and I was amazed of relative clarity of my vision.

The eye exam will improve with time.

Yes, I am interested in what you have learned about PRK. I am using PCM to correct my myopia. I am studing Ortho-K and PCM and will continue to bring information about both to this list. I personally believe that Ortho-K or PCM should be used before surgery. These techniques achieve the same as surgery but take a while longer (and possibly more expensive). Since I have experience with PCM I can talk about my successes and failures.

I joined the i_see list to gain knowledge about different eye care and correction techniques. You are the first (since I have been on the list) that is willing to give your thoughts on the subject about what you expect from surgery. I would also like to hear what you had to go through on a personal level. What happens during and after the surgery...

Since few people on this list have had surgery or used Ortho-K or PCM, there is little personal experience with these techniques available. The people using these techniques don't need a support group. They use their doctor and his patients for support.

The VT and Bates techniques are outside the commercial vision treatment system. Support for these techniques outside of this list is rare. I believe that without the support this list gives to these people, this list would die. Also, these people would possibly discontinue these techniques in frustration, because of the length of time needed to achieve results. I have learned many things from this list and am grateful these people have gotten together. Insight can be achieved from this list immediately or over many weeks.

Another thing that has made this list successful is the importance sight has in each person's life. In contrast, dental problems are fixed and you continue your life without regard to your teeth until you have another problem. What if you could change the way you take care of your teeth and would not have to go to the dentist any longer. Or only have annual checkups. Simple techniques at home would prevent plak buildup, and no cavities... I would like to see a list on dental health care. Would there be enough interest to keep it going? One piece of information for you about dental health care, for those that do not know. You should, without fail, brush and floss your teeth before you go to bed! Once you brush your teeth *do not* eat or drink (except water) anything until morning. Following that advice will save you a lot of agony and expense. Well, this is not a dental group, enough said.

>And another issue. I don't know if this list has something like a
>mission-statement, e.g. VT only.

It probably shouldn't -- or else there should be separate lists for different kinds of myopia. But I haven't yet come across any comments on MHO that "myopia" is a blanket term as indefinite and non-specific as "fever" or "insanity." My two cents: VT is the only thing appropriate for some kinds of myopia, while PRK or ortho-K may be appropriate for other kinds... and I also predict that hormonal injections might prove necessary for yet another kind, psychotherapy for yet another, a combination of all of the above for yet another, and so on. But a dozen distinctly separate and different conditions masquerading under the common symptoms of blurred distance vision and the generic name of "myopia" is something yet to be discovered. So where we are now, I wouldn't go for surgery, or anything else that's invasive and irreversible. For several months, I've followed comments from post-PRK patients on sci.med.vision. They range from "the greatest thing I ever did for myself" to "if I knew in advance what it would be like I wouldn't do it" to "the biggest mistake of my life." Quite irrespective, as I observed, of the objective vision acuity achieved in each case. I think this may be more evidence in support of my idea: subjective satisfaction depends on whether the procedure just happened to be applied to the right or wrong case. And there's no way to be sure in advance which case you're going to be. If I had a control group of eyes on me I would probably try it myself.

Another concern: even if everything is perfect for a while... long-term effects? In 1987, I was scheduled to undergo RK in Moscow, in the clinic of prof. Fyodorov, the inventor of the modern (post-Japanese) RK method. They'd been doing it for at least ten years by that time, maybe more. I now bless my lucky stars for procrastinating and being indecisive as long-term

results of this mass butchery begin to surface.

In my book *The Power Behind Your Eyes*, I cite two cases I have personally interviewed after eximer laser surgery for nearsightedness. In one case, after the surgery, the man developed a floater that became so annoying that it affected his daily life. He became very depressed, lost his job and went into clinical depression. In the second case, a doctor developed a detachment of the retina and could no longer see patients. He has now filed a law suit against the ophthalmologist. In the third case, a woman I saw had -15.00 diopters in her glasses had a very successful surgical correction, and now wears a weak prescription for day time use. She is very happy.

I am photographing my clients corneas, who have the surgical procedures for correction of nearsightedness and placing it in their files to take out in a few years for comparison.

I report my examples and let others make their choices.

True. I would never undergo RK, even if they give me money for it. When I first heard of RK about 10 years ago I wondered when the cornea stops to flatten following the incisions. The fact: it may never do. THE benchmark study of RK is the PERK (Prospective Evaluation of Radial Keratotomy) study, carried in the US for about 12 years in the 1980s and early 90s. It found that a large proportion (43%) of eyes changed in the hyperopic direction by 1.00 D or more over the course of the study. Second, the structural strength of the cornea is forever weakened. There have been quite a few cases of cornea bursting after blunt traumas (a good review is in the Feb 96 issue of Arch Ophthalmol). Third, fluctuating acuity is also a concern. In sum, RK - forget it. I can't comprehend how on earth about 200-250,000 people have RK in the US each year.

PRK, in contrast, looks much safer. The corneal strength is not compromised. By virtue of the procedural method, there is no long-term hyperopic shift. But there may be a myopic one, this only time can tell. There is always some degree of regression due to stromal remodelling and that's why surgeons allow for it by "overcorrecting". Yet, the restoration of the epithelium and its anchoring to the anterior stroma does act like a blocking mechanism to excessive collagen build-up, i.e. regression. Well, I might be getting too technical here, although I have bearly scratched the surface.

Elena wrote:

>the right or wrong case.

Agree. I would also ask WHY are they unhappy?

Satisfaction=reality-expectations. Patient satisfaction studies show that the main reason of dissatisfaction is Regression of Effect, i.e. reversing back to myopia (the reason being stromal wound healing). If a 20/800 myope has 20/20 vision for a month after PRK and then slips to 20/60, he or she may still be happy. A 20/100 myope, on the contrary, who undergoes PRK hoping to get rid of lenses forever and finds himself with 20/40 after surgery, may fall into depression. The exact pharmacologic manipulation of the corneal wound healing after PRK is currently a hot research issue and things are bound to get better.

Another aspect, WHEN did they have the procedure? Earlier PRKs were done with a smaller ablation diameter 4-5mm. At the same time the pupil's diameter in darkness is usually more than 5mm - about 5.5-6mm. Light coming into the eye thus gets refracted differently and night vision becomes a nightmare. I've spoken to a guy from Germany who had PRK with 5mm and who said that during the day he could see fine, but his night vision was "trashed" (his word). Current PRKs are usually done with 6mm, most lasers can ablate up to 7mm in diameter. I would urge everybody considering PRK to have their pupil diameter measured in darkness. If it happens to be 7mm or more, one should think twice about PRK.

PRK is not without risks, of course. Haze is often cited, but usually it clears within a few months (haze is caused by "SOS" behavior of specific cells, keratocytes, in the corneal stroma. They gradually "calm down"). My biggest concern is the loss of Best Corrected Visual Acuity. I am not willing to sacrifice *ANY* of my BCVA. Currently loss of 2 or more Snellen lines happens with about 5% of eyes. Data is scarce about the percentage of eyes losing one line (one line is considered within the "noise" of measurement), but is probably in the teens. I am extremely risk-averse in this situation, with my acceptance level being around 0.01% for loss of two lines. The primary reason for loss of BCVA is the inducement of irregular corneal astigmatism, which, in turn, is most often caused by unhomogeneity in the laser beam. No ophthalmologist will tell you this. Enter the specifics of different laser systems, maintenance procedures, beam characteristics, etc. A limited number of companies offer choice of equipment, few patients make an informed decision. I am no guru myself, so don't ask me whose laser is best; but I'll research the issue thoroughly when time for my PRK comes. Homogeneity may differ from machine to machine, depending on calibration.

Solid-state lasers (they use crystal to generate the laser) offer a much more homogenous beam, but they are still not in wide use.

So far, most PRK stories that I've heard have been positive, including by myopes in the -8-9D range. I continue to prefer PRK over the much touted LASIK. But it should be clear that although VT does not end with refractive surgery, the latter is a betrayal towards VT. Pure VT faithfuls should not taint their life with refractive surgery.

Disclaimer: I've offered the above in good faith but I am not a doctor and will not bear any responsibility for action or inaction taken in connection with the above statements. Consult an authorized medical professional for your vision care problems.

(Sorry, fact of life)

Stefan

I have nightmares about a member of this group getting into an accident on account of becoming as adventurous with driving as with other activities. I'm all for adventure and exploration -- but driving is the only thing I feel like leaving out of this until/unless I have at least a permanent, reliable, unfluctuating 20/40 with whatever I use (weaker glasses or the new, improved bare eyes). I would strongly urge others to follow suit. You don't want any additional risks in situations like encountering a pizza delivery boy who loses a bonus unless he delivers it on time and runs a red light at 60 mph (true story that cost my previous car its life and nearly cost me mine... but I did have a split second to react, something I might not be able to do if I saw him this split second later.)

And George -- congrats on your success!

Elena

Hello! I am new to the mailing list and would be interested in hearing from people who have had results from their VT. I would like to know what kind of results you have experienced, how long it took for you to have results and what exercises or relaxation techniques have worked best for you. I have just started VT and don't really know what to expect but I am quite excited about the prospects. I think I probably need a reality check so I don't get discouraged if I don't see any immediate results.

I also have a few other questions. I would be interested in knowing what percentage of myopes have allergies or food sensitivities. This may sound a little odd but a few weeks ago there was some talk on your list about protein deficiency maybe being linked to myopia. In addition to being a myope I also know that I have both allergies (food sensitivities) and protein deficiency. I see the latter two as going hand in hand. Often (I'd say in all cases) we develop allergies because of our inability to properly digest protein, usually because of a lack of enzymes in our system. This in turn becomes a cycle in that without properly absorbing (or digesting) the proteins that we eat, we cannot produce the enzymes that we need to digest them...and so it continues. In my own little analysis, I was speculating that if indeed we as myopes tend to crave carbohydrates instead of proteins, maybe it is because our digestive system is in such a state that we can better deal with carbohydrates. Just a thought. Have any studies been done on this subject?

Was it here that I read that myopes also tend to be low in salts? Something else I have been diagnosed as having. Of course these are things that I am in the process of correcting hoping that it might facilitate my quest for better vision, and improve my health of course.

One last comment, bags or dark circles under the eyes are very often caused by food allergies. If they are dark circles that never seem to disappear, it would be my suspicion that they are caused by a food that you are eating

on a daily basis (ie milk or wheat). I think it was George who was inquiring about this subject.

I look forward to hearing any words of encouragement about vision therapy.

I'm certainly not interested in any walls.
There is no absolute knowlegde. Since it apriori
excludes experiences which are not easily repeatable,
demonstrable to others, or communicable, scientific
skepticism can never claim to be a method that leads
to complete truth. It is useful indeed, but partial.
Fortunately, VT is demonstrable.

(Sorry, I just like to reflect on paradigms.)

Well here is a different explanation, which I got from a book called "Eye Strain" by V. Brumer. It seems appropriate. Brumer was a Manchester optician who believed in the "plus lenses good -- minus lenses bad" theory. His book is on how eye strain, or as he calls it "uncontrolled visual functioning" takes its toll on the eyes. According to Brumer, excessive near work and minus lenses are both prime causes of eye strain. He recommends plus lenses for schoolchildren as a means to prevent myopia as well as other "depredations". He also says eye strain is the ultimate cause of every other eye disease. Anyway, here is what he has to say about dark bags under the eyes.

The cosmetic depredations caused by eye-strain can range from mild to very severe forms. In its mildest form it is exemplified by the discoloration of the tissues immediately underneath the eye. These discolorations are commonly termed black shadows and in their most intense form they can, indeed, be very black. It is a symptom of the excessive energy demands of the eye, whereby the immediate surrounding tissues are robbed of their due share. The explanations hitherto put forward for these manifestations are evidence that they have not yet been properly understood. Kidney disfunction, undernourishment, worry, lack of sleep, menstruation and disturbances of the reproductive organs have all been enumerated as likely causes.

No attempt has been made to explain why these symptoms should make their appearance immediately around the eyes. Why, for example, should not worry and lack of sleep induce acute discoloration of other parts of the face, such as the upper lips, the chin or the forehead? Quite obviously because these symptoms are of local significance. That the medical profession has not yet realised a proper valuation of these symptoms is evidenced by a general practitioner writing in the /British Medical Journal/ of October 16, 1937. He describes the case of a young woman recovering from a bad general breakdown and the appearance of black shadows under the eyes. The shadows vary in make-up as a causation was dismissed after a lengthy period of observation. The doctor was inviting suggestions for getting rid of intensity, being palest after a good night's sleep. The incidence of the shadows.

This is obviously dated; you can ask around on sci.med.vision to see if any better theories have come up. By the way, George, if you or anyone else in the UK could help me find the person who now owns the publishing rights to this book "Eye Strain" I would greatly appreciate it. I'd like to make large portions of it available on the web. The book was published by "Victor Optical Company", St. Helens -- Lancashire in 1953.

Subject: Re: Acuity can be improved
Date: 21 Feb 1996 08:35:55 -0500

Dear Alex,

From what I have read in my spare time, there is a lot more that we don't know than we do know, whether we are doctors, M.D.s, or not. I see in my reading and in my patients much data that conflicts with the generally accepted paradigm, at least in the U.S., that myopia is structural.

I can't remember any of my own obese patients ever loosing 100 lbs, though I've met many who needed to. I'm sure all my obese patients could loose the weight though if they stuck with the lifestyle changes necessary for success.

From what I've read on the epidemiology, myopia is a condition of use/abuse, close up work in succceptible eyes. It can't be a genetic normal biological variant and increase so rapidly over two to three

generations. If it's like obesity, then it will take a very dedicated person with severe myopia to make the necessary lifestyle changes to reverse it. I see no long term studies controlling all variables proving that vision therapy does not work. I've read many showing vision training, biofeedback, reading glasses etc, do work short term. I've tried these changes myself and have had some success. When I stick with the program, my vision improves, I even had it objectively measured by a behavioral optometrist who found a decrease in my myopia of about one diopter. But of course, she was not an M.D. and therefore was not scientifically trained with multiple choice and true false quizzes and sleep deprivation training during her residency so she was obviously biased and confused. So I went to lens crafters and had a non-biased person measure and confirm the same improvement.

At times I can see 20/20 so I know however unscientific this knowing is, that at least briefly, the focusing mechanism of my eye can overcome its excessive length. This is fun but also a little upsetting after wearing glasses for 25 years and seriously considering eye surgery. None of my physicians ever mentioned vision training as an option. Basically, I'd like to say that I appreciate your comments. I think each person should feel free to look over the information for themselves and not just let a specialist do their thinking for them.

Sincerely,

A functional myope and family physician
julie

Excellent point! I wonder if this is how obese people feel: Becuase of my everyday and demanding close work (I'm a software engineer), I feel like there is now way that I can stop wearing my glasses or contacts, I'm too dependent on them.

I am currently considering eye surgery myself. In particular I'm looking at having the PHOTOREFRACTIVE KERATECTOMY (PRK) otherwise know as the Excimer Laser surgery. I have talked with people at the the Maddox Excimer Laser Center (El Paso Texas) about it and they say that I am a good candidate for this surgery. I have talked to someone who had it done and she said that she was at a -9 and that now she is at 20/20. I do have to stay off my hard contact lenses for at least 3 months, so I guess this means that I have three months to think about.

> of my physicians ever mentioned vision training as an option. Basically,
> I'd like to say that I appreciate your comments. I think each person
> should feel free to look over the information for themselves and not just
> let a specialist do their thinking for them.

Wow, I must admit that I'm impressed about a specialist admitting to the fact that they are not gods or know-it-alls ;)

>
> Sincerely,
> A functional myope and family physician
> julie

I have about 60 pages of literature from the Excimer Laser Center, I can share important bits from it if there is interest. I would like to hear about any pros or cons that people in this group know about the laser (PRK) surgery.

Thanks in advance,
Mario Torres

Edythe, the "V" stands for "vision" or "visual", and the "T" stands for
"training" or "therapy". I think the reason people use the abbreviation
is because they can't agree on which words to use!

By the way, this abbreviation originates from the optometric profession.
Ophthalmologists tend to use the word "orthoptics". Most "normal" people
would simply say "eye exercises" in place of all these expressions but for
one reason or another most eye doctors in the business try to avoid this
expression because of what they think are bad connotations. Bates often
used the term "eyesight education" or "re-education" because his method
emphasized the mental side of sight, particularly imagination and memory.

Subject: vision therapy

Hello! I am new to the mailing list and would be interested in hearing from people who have had results from their VT. I would like to now what kind of results you have experienced, how long it took for you to have results and what exercises or relaxation techniques have worked best for you. I have just started VT and don't really know what to expect but I am quite excited about the prospects. I think I probably need a reality check so I don't get discouraged if I don't see any immediate results.

I also have a few other questions. I would be interested in knowing what percentage of myopes have allergies or food sensitivities. This may sound a little odd but a few weeks ago there was some talk on your list about protein deficiency maybe being linked to myopia. In addition to being a myope I also know that I have both allergies (food sensitivities) and protein deficiency. I see the latter two as going hand in hand. Often (I'd say in all cases) we develop allergies because of our inability to properly digest protein, usually because of a lack of enzymes in our system. This in turn becomes a cycle in that without properly absorbing (or digesting) the proteins that we eat, we cannot produce the enzymes that we need to digest them...and so it continues. In my own little analysis, I was speculating that if indeed we as myopes tend to crave carbohydrates instead of proteins, maybe it is because our digestive system is in such a state that we can better deal with carbohydrates. Just a thought. Have any studies been done on this subject?

Was it here that I read that myopes also tend to be low in salts? Something else I have been diagnosed as having. Of course these are things that I am in the process of correcting hoping that it might facilitate my quest for better vision, and improve my health of course.

One last comment, bags or dark circles under the eyes are very often caused by food allergies. If they are dark circles that never seem to disappear, it would be my suspicion that they are caused by a food that you are eating on a daily basis (ie milk or wheat). I think it was George who was inquiring about this subject.

I look forward to hearing any words of encouragement about vision therapy.

Plus lenses create more far-sightedness in non-myopes?
I don't fully follow what Dr H is getting at below, but allow me
to recount my experience (as a non-myopic amblyope):

With my "good" eye, I have always had excellent distance vision without
glasses. (I stopped wearing my prescribed (strongly plus) glasses at
age about 16, mostly out of vanity, but also as even my eye doctors
said they would do no more good after about this age).
However, in my mid-40s, I finally gave in to the idea that I must be
by now presbyopic, since reading small print by anything other than good
daylight was becoming painful to impossible, and using a VDU was getting
more and more stressful. However, at this time, my distance vision with
my "good" eye was subjectively as good as it had ever been.

About 12-18 months ago, I started wearing drug-store reading glasses
to help with the above situations (+1 or +1.5). I must admit that
in some cases, I was too lazy to take them off and put them in the case,
and sometimes would find myself wearing them to get about the house, or
get about my office building. Whether it was the latter behaviour or
just using the plus lenses at all, I am sure that my distance vision

suffered as a result; perhaps not permanently, but definitely for some time after taking the reading glasses off. e.g. I found I was screwing my eyes up to recognise people in the distance that I never used to have any problems with.

My own "theory" about this is that while the reading glasses are great for giving your (presbyopic) eyes a break, i.e. by essentially doing the focusing for them, they also allow them to get very lazy, and I suspect this is why they appear to affect distance vision after prolonged use. (I'm using "lazy" in the colloquial sense, not in the "lazy eye" sense). In summary, my feeling is (as my gut feeling always was before ever trying them) that reading glasses, unless used only for the minimum, can do harm to your "natural" eyesight (despite what the ads for them say). You must not - as I did - start to depend on them totally. I am now trying to wean myself off them gradually, and will be trying to go back to the path of VT (in a general sense - I am not convinced about any one method, I have to say).

This may not have much to do with Dr Harris and his theories, since I guess in the general case, he is not talking about presbyopic eyes, but I pass it on for what it is worth.

Mike.Ellwood@rl.ac.uk

>
> Stefan

Good point. I guess it would be up to the moderator (Alex) and the rest of the subscribers. I would think that its okay to discuss as an alternative to VT and weigh the pros and cons accordingly. Certainly with that in mind, before we engage into the debatables, we must present the facts that we have on hand. As of now PRK surgery is a much more expensive and perhaps less emotionally rewarding alternative to VT. I am also trying to dig for some unadvertised side-effects or consequences of PRK, I'm a bit leary of the literature given by the PRK clinic and I wonder if its not a bit biassed.

I will wait a bit for more feed-back to see if we should post here or else we can create our own email exchange. There are a couple of other people who want to know more about it.

Mario

Yes Elena this is exactly my concern, what are the long term effects? Its hard to swallow that so far there are "NONE" published or presented by anyone. Its one of the feelings like if its too good to be true. I guess the best way to find out is to get feed back from people who have had it done. I just recalled that one of my cousins who now studies in Rome had it done in Mexico a few years back. I have to admit he was one of those initial brave souls, then he said that it was great and that he was glasses free, wow! I will write and post how long ago it was since his surgery and what his comments are now.

Hasta la vista,

Mario

Can you get any more information from this guy? Like what kind of surgery it was? How long did it take to heal? How does he know myopia is returning? To what degree? What was the myopia in terms of diopters before surgery? and after?

Thanks in advance,

Mario

Mark:

If you are a myope, then pulling your glasses further away from your eyes makes the glasses less minus, so you are getting better. If you are a hyperope, just the opposite.

I've heard that there is a method where this surgery is done by cutting with surgical knives as well as the method using laser. I know in Ecuador and Columbia it can be performed with surgical knives, supposedly with good success. Is there any difference in the results of these different methods of surgery--either short or long term? Has any study been made on these differences?

Hello, can anyone help me?

I've been trying to improve my eyesight with various techniques and feel a lot more confident about leaving my glasses off.

My problem is that when I wear my glasses normally, they strain my eyes. When i pull my glasses on to the end of my nose, everything is comfortable again.

Does this mean that my eyesight is improving?

PRK - Too good to be true?

- *Subject:* PRK - Too good to be true?
 - *From:* stefansi@ctrvax.Vanderbilt.Edu (Stefan Ivanov Stefanov)
 - *Date:* Mon, 26 Feb 1996 22:32:04 -0600
-

Somebody suggested that PRK was too good to be true. (I've been purging my mail boxes lately, and appologize for not recalling the name).

I want to strongly oppose this too-good-to-be-true attitude. It denies (or at least is slow to accept) scientific progress and usually underlyes a non-inventive mindset. History is full of examples of similar resistance, from the automobile (this thing cannot work), to the airplane (this thing cannot fly), to today's article in the Wall Street Journal ("Persistent Inventor Markets a Molecule", p.B1). I do not mean to say, as previously stated on the list, that a certain dose of scientific scepticism is not beneficial.

I maintain a fairly sizable database of people who have had refractive surgery, mainly PRK. The vast majority of them (98%) are very satisfied. I contact these people on a regular basis to follow their progress. Just two examples (and they are typical, not chosen for flashy commercial purposes):

a) A 38 year-old lady underwent PRK bilaterally approximately four months ago. Was about -8.0 D in both eyes before surgery. She now sees 20/25 and 20/30, her vision is pretty stable, has virtually no haze, and she feels like reborn. I met her on the Internet, and we have a very good 'net relationship. I completely trust her and touch base with her frequently.

b) A man in his late twenties had PRK one year ago. Was -3.0 D before surgery. He now sees 20/15 and 20/20 and has no complaints. "I see road signs before anybody else in the car", he told me when I called him earlier this evening. (He was one of my still "unexplored" references. I feel perfectly OK cold-calling such people as we all share a common pain. He lives in Detroit.) On the question about pupil size vs ablation diameter he said the doctor had told him that people with blue eyes and blond hair on general have larger pupils and should be more careful when deciding to have PRK. Presently I have no data to support or refute this observation.

Stefan

PRK - Long term complications

- *Subject:* PRK - Long term complications
 - *From:* stefansi@ctrvax.Vanderbilt.Edu (Stefan Ivanov Stefanov)
 - *Date:* Mon, 26 Feb 1996 23:14:17 -0600
-

Of course, nothing can reveal long-term complications of PRK except time or clairvoyancy. But some basic intuition is usually helpful (sceptics will say that people's intuitions differ and only hard facts matter - well, I can't refute this argument, but even scientific hypothesis testing starts with intuition).

The following are four major areas of concern regarding possible long-term complications after PRK:

1. Stability of refraction. Acuity is considered generally stable after two-four months, but may fluctuate up to two years. Gradual regression into myopia is not improbable, but so far I haven't seen a longer-term study on this (and I am closely following the leading ophthalmic journals). I am not referring to the initial regression which is "normal", but to long-term creeping regression.

2. Potential keratoconus. The thinning of the cornea and the irreversible destruction of Bowman's layer makes the cornea more susceptible to bulging due to the intraocular pressure. Certain experiments have concluded that there is no risk for keratoconus provided the central depth of the ablation is less than 150 micrometers. You can calculate the central depth of your potential correction using the following approximating formula:

$$\text{Central Depth} = (D*d*d)/3 ,$$

where D is the attempted correction in diopters, and d is the ablation diameter in millimeters. The result is in micrometers. You may assume d=6 mm. The formula yields an error of about 0.5-1.5 micrometers as compared to exact values. The total thickness of the human cornea is about 500-520 micrometers.

3. Ultraviolet irradiation. Reduced corneal thickness poses a risk for increased UV irradiation the results of which are hard to predict.

4. Persistent haze. Some of the haze may not clear. This may be annoying even if the person sees 20/20.

Stefan

When i looked into laser therapy about 5 years ago i was told that, in Canada, it was not possible to have this procedure done since i was over 30 and had more then a -5 prescription.

When i asked about it, i was told that some studies had shown that people over 30 tend to revert rather quickly to their myopic states after the operation. I also learned that removing as much tissue as would be required to correct over -5 would be dangerous to the future of my eyeball.

Since i didn't meet either of their conditions, i turned to VT and spent the \$6,000 on a car. I didn't look into the matter any further so i'm afraid i can't quote the sources of these studies. Perhaps some Canadian opthamology organization would know more.

I expect that many of us received a mailing from Brian Severinson telling us about his product 'Vision Freedom'? Does anyone know anything about these glasses?

I would appreciate hearing what anybody knows, although if they are a complete waste of time, please be gentle because i have already sent him my money -- i like to think of myself as open minded but perhaps i am just a sucker after all!

I even sprang the extra 4 bucks for the rush delivery so my hot little packet is probably already on its way. He guarantees results within 6 - 8 weeks or money back. As a person who has been using VT methods for over 4 years, i'm willing to give it a try.

I'll let you know what i find out. If you didn't get a note from him, the web address is:

<http://www.sisna.com/vision>

Description of PhotoRefractive Keratectomy (PRK)?

- *Subject:* Description of PhotoRefractive Keratectomy (PRK)?
 - *From:* Mario Torres <mtorres@wsmr-relay2.arl.mil>
 - *Date:* Tue, 27 Feb 96 15:54:08 MST
-

Following is what I've copied so far from the information given to me by a clinic in El Paso Texas. I've included some of my comments within brackets {}. I will latter post more details about PRK. This will serve as a basic introduction to the more clinical details to follow latter.

Mario

What is a PhotoRefractive Keratectomy (PRK)?
(Some of the basics)

Excerpts from Patient Information Document No. 711168
Summit Technology, Inc.

PRK is a surgical treatment for nearsightedness in which an excimer laser flattens the front surface of the cornea by removing small amounts of tissue.

WHAT IS AN EXCIMER LASER?

A laser is an instrument that can produce and control a powerful beam of light. Laser light can be directed and controlled more precisely than normal light, and it can be delivered in extremely brief, intense pulses.

The excimer laser produces a beam of ultraviolet light in pulses that last only a few billionths of a second. Each pulse removes a microscopic amount of tissue by evaporating it, producing very little heat and usually leaves underlying tissue almost the same.

HOW IS PRK PERFORMED?

A specially-trained eye doctor uses the beam from the computerized laser to remove small amounts of corneal tissue, precisely reshaping the cornea.

PRK has been studied for six years before approval in the U.S. It uses a computerized laser to correct myopia (nearsightedness). The excimer laser is well suited for corneal reshaping, because the removal of just tiny amounts of tissue can produce the results you need to correct your nearsightedness.

Prior to PRK, some drops are placed on the eye to numb it. Use of the laser beam lasts about 15-40 seconds. The laser removes a small portion of the surface tissue to reshape the cornea. This treatment is performed on one eye at a time. The second eye can be treated if all goes well and vision stabilizes without complications or adverse reactions. PRK of the second eye can be done 3 months after the first eye. {Actually I've heard the second eye can be done as early as a week or two after the first eye}

After this treatment, most people report that they no longer need to wear glasses or contact lenses. In the clinical trials, 66% of people could see 20/20 or better after their vision was corrected, and greater than 90% of people could see 20/40 or better, reporting that they could function normally and even drive without glasses or contact lenses. The remaining people experienced an improvement in vision without glasses or contact lenses but may still need to wear glasses or contact lenses for some tasks. PRK does not eliminate the need for reading glasses. In some patients, reading glasses may be required after treatment even if they were not worn before treatment. Vision may take a few months to clear up and stabilize.

ARE YOU A GOOD CANDIDATE FOR PRK?

Anyone who is considering PRK should:

- Be 21 years of age or older
- Have healthy eyes which are free from retinal problems, corneal scars, and any eye disease.
- Have mild to moderate myopia within the range of treatment: -1.5 to -7.0 diopters of correction with low astigmatism of (≤ 1.5 diopters).
{ Though this is as advertised because of FDA restrictions, I've talked to someone who had the surgery done and she had -9.0 diopter }
- Be fully informed about the risks and benefits of PRK as compared to other available treatments for myopia.

- Know that health insurance companies do not cover this, they consider it cosmetic surgery.

{How convenient! And dental braces are not?}

The most common risks associated with PRK include glare, halo, and haze.

To: George Tohme
Subject: RE: Laser surgery

At 06:51 AM 2/24/96 UT, you wrote:

>I would really like to hear what people have heard/seen/experienced... in
>relation to laser surgery.

>
>Anyone cares to comment?

Almost all of what I've heard is negative; after 6 months to a year the eyes start shifting and your vision is blurry again. This happened to a friend of mine; she didn't want to wear glasses, and is now walking around in a blurry world because she'll be damned if she's going to put glasses on again after paying for the operation!

IMHO, the failure of laser surgery shows that their model is wrong. They're going on the assumption that the eyeball is genetically too long (or too short) and if you just alter the cornea to refract light differently, you'll adjust for the length and all will be OK.

They aren't addressing any of the models that say eyeball length is dynamic, can change over time based on physical, mental, emotional, nutritonal, etc. criteria, and therefore laser surgery is not going to work for more than a few months.

They're going along with their model, and saying more along the lines of

"Well, we just don't know exactly how to reshape the cornea, but with better lasers we'll get it right..." The concept that their model is wrong would probably send them into shock. (Plus laser surgery generates big bucks, so there's more incentive to turn a blind eye. :-)

George Tohme <PolySoft@msn.com> posted this forward from Sid Gudes:

>Almost all of what I've heard is negative; after 6 months to a year the eyes
>start shifting and your vision is blurry again. This happened to a friend
>of mine; she didn't want to wear glasses, and is now walking around in a
>blurry world because she'll be damned if she's going to put glasses on again
>after paying for the operation!

First, there is absolutely nothing wrong in wearing glasses after PRK. The perfectionist expectations of perfect, unwavering vision following the surgery border on naivety. Don't forget, PRK just carves your prescription on the cornea. After PRK you'll be always going around with your 20/20 (or whatever the result turns out to be) vision and we know what happens if you constantly wear your full prescription. Plus lenses should be emphasized even stronger, esp. in the first months after surgery.

Second, and much more importantly, the person's "propensity to myopia" (previously referred to as "susceptibility to myopia") must change. This is an exciting topic and I'll post about it later.

>IMHO, the failure of laser surgery shows that their model is wrong. They're
>going on the assumption that the eyeball is genetically too long (or too
>short) and if you just alter the cornea to refract light differently, you'll
>adjust for the length and all will be OK.

Genetically???? See my previous paragraph.

>They aren't addressing any of the models that say eyeball length is dynamic,
>can change over time based on physical, mental, emotional, nutritional, etc.
>criteria, and therefore laser surgery is not going to work for more than a
>few months.

The propensity to myopia is to blame, not laser surgery.

Stefan makes good points when he defends the new technologies being used to restore sight. It is indeed true that more often than not people tend to be very apprehensive when it comes to new ideas and procedures which latter on become the norm. Is this the case for PRK (laser surgery)? Is PRK the best, or at least straight forward, cure for myopia?

PRK is a fairly new procedure approved just last year by the United States' FDA, and the results are very encouraging and exciting for many. Following I share a few more details on what I have learned about PRK. I have to admit that upon reading this (and writting for posting) I have been fascinated by the detail and complexity of what is being done and achieved. As an engineer I have a good deal of appreciation for the thoroughness of the studies and research that evolved to produce PRK surgery. Read it and though you may begin to wonder if this is science fiction recall that this type of surgery is now being performed on thousands of persons each day. It has been estimated that as many as a quarter million people undergo some form of photorefractive surgery to heal their eyesight. (Humm... I wonder which stocks are related to this? ;)

Enjoy,

Mario A. Torres

Detailed Description of PRK
(PhotoRefractive Keratectomy)
Excerpt from an Informational Brochure
by Bobby Maddox, M.D.

Photorefractive keratectomy (also referred to as wide area ablation, corneal reprofiling, corneal sculpting, and laser

keratomelieusis) is the process of using the Excimer Laser to reshape the cornea in an effort to effect a change in the refractive characteristic of the eye and thereby correct or lessen myopia, (nearsightedness) hyperopia (farsightedness) and/or astigmatism. Using the Argon-Flouride Excimer Laser to accomplish photorefractive keractectomy is a dramatic departure from existing procedures such as radial keratotomy...

In PRK for myopia, the cornea is reshaped by the Excimer Laser without being cut or incised, normally effecting a change in the refractive properties of the cornea. The Excimer Laser uses photoablation, or high-powered pulsed ultraviolet radiation (light energy or photons) to remove tissue with an extremely high degree of precision. The excimer Laser is a unique computerized 193 NM Argon-Flouride laser which can reshape the front surface of the eye (cornea), acting at the atomic and molecular level, in as little as 20 seconds, without creating significant thermal damage to surrounding tissue. This special characteristic allows the Excimer Laser to be referred to as a "cold" laser. ("Cold" is a relative term, in that other lasers produce larger amounts of heat and thermal damage than does the Excimer Laser.) \

In an area of the central cornea, about the diameter of a drinking straw, 25 billion million photons (packets of light energy) per pulse shower down in a parallel fashion onto the cornea, photoablating, or removing, .25 microns of tissue with each laser pulse. [One micron equals one one-thousandth of a millimeter (1/1,000).] One cell (10 microns has to be hit or pulsed 40 times in order to be completely photoablated at .25 microns per pulse. The number of pulses needed to correct the myopia depends on the amount of myopia and the ablation zone size. Usually from 3% to 15% of the central corneal tissue is utilized for corneal reshaping for myopic corrections from -1.00 to -7.00

[An explanation of the size of a micron: The average single human cell is approximately 10 microns in height. The diameter of a single human hair is approximately 50 microns, and the thickness of the central cornea (the front surface of the eye) is a little over 500 microns (half a millimeter). Therefore, only one-tenth of a cell is penetrated by the excimer photons when penetrating one micron.]

Since each photon has energy equivalent to 6.4 electron volts, and the energy required to hold the protein atoms together in corneal tissue is only 3 electron volts, these molecular bonds holding protein molecules together in the cornea are broken, and molecules and atoms of tissue fly away from the cornea, .25 micron layer by .25 micron layer, at supersonic speeds. (This effect is referred to as the "plume of photoablated tissue." The laser's aperture (mechanical iris)simultaneously expands in a stepped fashion, until the desired optical zone and optical correction are achieved. Each pulse of 25

billion million photons acts only on those atoms of protein that are bonded together in an are of about 5 or 6 mm or larger, .25 microns in depth, or 1/40th of a single cell. (One cell is only 10 microns.) Each laser pulse last approximately 10 nanoseconds, which is 10 billionths of a second, at 10 pulses per second.

{ Next time we'll describe how Refractive correction is achieved by stepped photoablation with the Excimer Laser. }

Summit announces plans for national campaign

- *Subject:* Summit announces plans for national campaign
 - *From:* stefansi@ctrvax.Vanderbilt.Edu (Stefan Ivanov Stefanov)
 - *Date:* Wed, 28 Feb 1996 15:51:59 -0600
-

At around noon (EST) today Summit Technology, a Waltham, MA - based leading manufacturer of excimer laser systems for the correction of refractive errors announced its plans for a nationwide PRK promotion campaign. It also announced the opening of its first Summit Vision Center - in the Minneapolis/St. Paul metropolitan area (actually scheduled to open March 4). During the next three months Summit tentatively plans to open 18 additional centers across the USA (I have a list of these, if anyone is interested I can post it). These centers are the "spoke" part of its "hub and spoke" service system (much like the airlines). Some of the hubs - at leading medical institutions like Stanford Univ Medical Center, George Washington Univ Med Ctr - are already operating.

The promotion campaign is scheduled to air nationally around mid-April (it's been already running in selected markets since Jan 29). There will be a toll free number for a free brochure and everybody will be given the address of the nearest Summit Center and will be entitled to a free eye exam to determine eligibility for PRK. I already have the number (I called Summit last November) and will post it if there's interest (would've done so even now but don't have it handy. I posted it to sci.med.vision last year).

The company says that so far phone calls have exceeded expectations. A couple of warnings. Summit is closing its UK operations which it says were useful "beta sites" (???) and last week the founder and most dedicated person behind Summit, Dr. David F. Muller, sold all his shares (150,000).

Summit Technology is the only company cleared by the FDA to sell its device for laser vision correction. The Summit Vision Centers are entirely owned and operated by the company. It also sells lasers to other surgery providers (like Mario's El Paso company). I have no commercial interest in Summit.

Exercise: Shifting

- *Subject:* Exercise: Shifting
- *From:* Alex Eulenberg <aeulenbe@indiana.edu>
- *Date:* Thu, 29 Feb 1996 10:42:09 -0500 (EST)

Shifting is an exercise that has not been given the attention I believe it should be, probably because it seems to emphasize the extraocular muscles or the imagination, and "everyone knows" all functional focusing problems reside in the ciliary muscles. Nonetheless, I find the effects quite significant.

The procedure is simple. Direct your gaze at a point for a second and then shift your gaze to a point some distance away, a point that is in your visual field. When this happens, you should see a swing in the direction opposite to that in which your gaze shifted.

Let's take shifting on a letter as a concrete example. Suppose you're looking at the letter H. First you look at the tip of the left post (the asterisks delineate the center of your field of vision):

```

      *
    * | * |
      *----|
      |    |
  
```

And then you look at the top of the right post:

```

          *
        | * | *
        |----*
        |    |
  
```

When you do this, you should see the H swing to the left. This is only logical since the center of your field of vision remains in the same

place, while the image relative to it moves.

However that many people have developed the habit of staring, which is "grabbing on" to one detail of a picture and not letting the eye shift smoothly and quickly from one point of the scene to the next. As a result, instead of swinging in the opposite direction as it should, the image actually swings in the SAME direction, or a completely unrelated direction, or goes blurry.

The goal of the shifting exercise is to be able to shift your center of vision from any one point in your visual field to the another quickly and efficiently. The closer the points are that you can correctly shift between, the better your detail vision will become. But if you start out at points that are too close together in your visual field, this may cause discomfort and even poorer vision. So start out by shifting between two rather distant points, such as the corners of your thumbnail held at arm's length or closer, or the corners of a window on a distant building (of course any two real points become further apart the closer they are to your eye, and vice versa). Bates recommended shifting on various sized letters of the eye chart from various distances.

When you shift, do move your head from left to right as necessary. This is an exercise of shifting visual attention, not of moving the extraocular muscles per se. Perhaps a better way of saying this is that shifting trains all the muscles of vision, including the muscles in the neck. They are all coordinated. You may not realize this, but your extraocular muscles are actually "tuned" to your neck muscles so that when you move your head in one direction, your eyes automatically shift in the opposite direction. This is shifting, yes, in an absolute sense. But relative to the image at the center of each eye's retina, you're still remaining fixed on one point. What we want to train with the "shifting" exercise is the complete coordination of retina, extraocular muscles, and head muscles. Again, by directing your gaze with your head -- "panning" as they say in cinematography -- especially when shifting between two relatively distant objects, you are not compromising the value of the exercise.

How long should your shifts be, and how long should you pause at each point? This depends on how well you can shift at the distance at which you are shifting. If you are myopic, you may be able to shift better at the near point (or with your glasses on) than at the distance (without glasses). You should shift as quickly as possible from on point to the next without straining your eyes or jerking your head. I have found that shifting by the tick of the clock -- one second per shift is a comfortable rate, but depending on the distance, it may take more or less time for you to "center in" on your point of

destination.

Be sure to try out all these variations:

- 1) With right eye covered
- 2) With left eye covered
- 3) With both eyes closed (no kidding! Try shifting in your imagination what you have been looking at with your eye; this benefits your real-world shifting)
- 4) In three dimensions (also called "zooming")
- 5) Shifting with eyes only
- 6) Shifting with the neck
- 7) Shifting with the torso

--Alex

Torres Mario <mtorres@wsmr-relay2.arl.mil> wrote:

>Is PRK the best, or at least straight forward, cure for myopia?

Is PRK actually a cure for myopia? Gosh, I don't know. I am tempted to say it's not, because, again, like the case with lenses, it just corrects for refractive error. But what will **any** real cure do if not correct for error? Then the important question becomes **How?**.

Myopia is damn so multifactorial. Is the cause only in the mind (as Elena has also suggested)? It's not that simple. My answer is that the cause for myopia is **close** to what you think it is. "Close" because there is the unconscious which supposedly you can't entirely look into. But then one out of four people in the US is myopic; this figure is about 70-80% in South-East Asia. Myopia afflicts people from all walks of life, including sophisticated "mental types" as well as outright simplistic unthinking persons. The latter just don their glasses (or lenses) every morning and don't even think about their myopia. What is the cause for **their** myopia? I can be hardly sold on it being emotions. It's simply near work (in this 20th century).

So for those who think myopia is in their mind, the cause for myopia **is** in their mind. For those who don't think about myopia, the cause for myopia is out of their mind. Assuming that most people on this list are of the mental type, I should say that PRK is not likely to be a "cure" UNLESS the person is so satisfied (subjectively) with the result that it elevates him to new heights of vitality and he/she embraces life in all its exuberance wondering how on earth he'd let himself writhe in the clench of myopia and vowing never to lapse into it again. Such a stance, btw, should stop an otherwise non-malignant myopia from progressing.

Sorry I have no idea.

A bit spooky about them using little old UK as a "beta test site".
Even IBM aren't that arrogant...

That's the problem with a helluva lot of medical conditions, by no means limited to ophthalmic ones. There's hardly anything chronic that modern (or maybe any -- but all we know is modern) medical intervention is successful in curing. At best, it can take care of some of the symptoms for some time in some people. At its worst, it generates scores of iatrogenic (doctor-made) conditions (some researchers suggest that the ratio is presently 1:3 in developed countries -- that is, one iatrogenic condition for every three natural diseases). I've been gathering some interesting statistics... The death rate in patients who undergo heart bypass surgery is about three times that of patients who have refused a suggested bypass. In members of the latter group who undertake lifestyle and dietary changes, it drops still further. I suspect that emergency medical interventions have shaped themselves to be a lot more efficient than any interventions into chronic conditions simply because in emergency cases, there's direct feedback (the patient lives or dies, for instance, depending on the treatment administered); besides, doctors gain nothing from keeping an emergency patient sick forever. I'm not paranoid enough to suggest conspiracies everywhere -- but logically, isn't an inherent conflict of interests involved in a hypothetical situation where a chronic condition sufferer comes to a doctor, gets a cure, gets well... and never comes again? And never pays again? Just wondering...

>

>Myopia is damn so multifactorial. Is the cause only in the mind (as Elena
>has also suggested)? It's not that simple.

I'll take credit for "multifactorial," Stefan, 'cause that's what I've been

talking about all along. I refuse to take credit for "only in the mind" part. Why would I delve into neurochemistry and neuroendocrinology if I were the proponent of the "only in the mind" view? I would just aummmm away...

I don't know if "holistic" is still a bad word -- if it is let's assume I'm just using it in its simple vocabulary meaning, derived from "whole" -- but I think it's the only approach to myopia with full success potential.

> My answer is that the cause for
>myopia is *close* to what you think it is.

Good answer. Includes the iatrogenic aspect too, btw. Myopia is not only close to what you think it is: it is also close to what your doctor thinks it is. If you trust your doctor, his/her professional opinion becomes a suggestion, a self-fulfilling prophecy. In my case (I always revert to "my case" not because I'm generally this self-centered but because it's something I really really know... better than any doctor knows any case unless he/she studied it from within), the suggestion was powerful because I was 13, the doctor was a friend of the family, and I didn't have a grain of information in my mind that could possibly grow into a clear crystal of doubt. This is what she said: "Your myopia will progress till you're about 18. Then, if you're lucky, it will mostly stop progressing, or it might progress very slowly. But right now, you can't do anything about it -- just wait for it to play itself out. And btw try to avoid wearing glasses whenever you can."

The phrasing was so final -- not a "maybe" and only one "if" -- that my hopes and choices were cut off at the bud. The only thing I could do, the only loophole left, was this "lucky" part: I wished myself luck and never got "malignant," destructive myopia that most people with this high an error have to deal with. If the doctor had said something to the effect of, "well, your grandmother is half-blind from myopia complications, so your genetic prognosis is hopeless, so brace yourself for the worst scenario," God only knows what I would be dealing with right now.

It's not all in the mind -- it's not all in the eye -- from my experience, it's everywhere. Since PRK is not something that can get "everywhere," has ample potential for iatrogenesis of new problems, and so on, it is, in my opinion, neither better nor worse than any other symptomatic treatment (like glasses) and is plagued by the same problems. Of course there's this aesthetic fascination with high-tech paraphernalia... but I would be a lot more impressed with a high-tech street sign a myope can see at night... as would George in Sydney, from what he's telling me.

Elena

My case

- *Subject:* My case
 - *From:* Ted <vmgreen@VETMED.VETMED.MISSOURI.EDU>
 - *Date:* Fri, 1 Mar 1996 11:23:07 CST
-

Greetings from a "lurker".....I found your list about a month ago and read the archives and other material, then joined recently. The comments, charts, exercises, and especially the support have all been very helpful. There have been questions and threads posted that I think that I can contribute to, so here goes. Elena and others, I hope this is helpful.

I've worn glasses for myopia since my teens, and found them very restrictive, so in 1970 began wearing contacts. All went well until about 5 years ago when I began having occasional episodes of conjunctivitis in my left eye. This progressed to more frequent bouts, and then to painful iritis/uveitis in 1993. (By this time I also needed +2 lenses over the contacts to read effectively.) I was seen by professionals twice during flareups and treated aggressively with mydriatics and steroid therapy. I was advised that the contacts "had nothing to do with it". I then discovered independently that I was allergic to thimerosal in the wetting solutions and went to thimerosal free products. This helped but the "red eye" continued at approximately weekly intervals, and finally I could not tolerate a contact in my left eye at all. I took it out for good, but continued to wear a contact in the right eye. About then (Summer 1993) I learned of Wm. Bates' work and found his book "Better Eyesight Without Glasses", read it and put his methods into practice. At that time my current script was LV -5.0 and RV -6.25, with no astigmatism in either eye. The first few days/weeks without the left contact were difficult, but manageable. I began keeping records on my left eye, as suggested; when I began I could not read ordinary 10pt type further than 8" from my naked eye. Using Alex's recently posted formula:

1 meter / distance from eye to read clearly = approximate (-) diopters
I had fairly good agreement with my script. 8" equals -4.92 diopters.

A summary of my progress:

month	read 10pt type	read diamond pt.type
Jul 1993	8" -5.0 script	ND
Feb 1994	11" -3.5 est.	5"-10"

Mar	1994	14" -2.8 est.	5"-14"
Apr	1994	15" -2.6 est.	5"-13"
May	1994	16" -2.5 est.	5"-13"
Jun	1994	15" -2.6 est.	5"-13"
Aug	1994	17" -2.3 est.	ND
Jan	1995	20" -2.0 est.	4"-12"
Feb	1996	22" -1.8 est.	5"-17"

I haven't been measuring the acuity regularly in the right eye as I felt that the lens compromises any evaluations. But I have some observations. Throughout 1994 to present, my reading distances with that eye have varied between 12" to 13". Diamond pt consistently around 4" to 11". There are some subjective comments that I can make as well. When I started I resolved not to wear contacts at all (right eye) unless at work or driving. My naked vision initially was bizarre at best. My three rail fence on the farm appeared to have 4 and sometimes 5 rails, if I could see them at all. I couldn't identify my 2 oxen individually at more than a few hundred feet. I sometimes misjudged my footing. The moon appeared to be a brilliant multi-moon raspberry. But much of that has changed. I can now make out individual strands of barbed wire at 50+ yards. I can ID my team at 200 yards. I seldom misjudge my footing on rough ground. I can read the red numerals on the bedroom digital clock at night at 12 feet most of the time. Perhaps, though, one of the most interesting phenomena has been that while viewing tv in the evening my left eye has improved but not clear vision at 12 feet, but my naked RIGHT eye after a few minutes relaxation has near perfect vision at that distance. And during the day around the farm I often realize now that my "uncorrected" vision is very good. I read comfortably without plus lenses with my left eye alone...my right eye is "tuned out". Another significant change is obvious on the highway at night (I DON'T DRIVE AT NIGHT ANYMORE!, my wife is very supportive). At first I had lost visual fusion between the eyes at distance, so that the sharp (right eye) tail-lights, headlights, appeared to separate from the very blurred (left eye) images. Lately this has changed as I have apparently reached a new plateau. Now those lights stay fused, appearing as sharp centers with a halo. At the same time during daylight I am now able to read street and traffic signs with minimal difficulty. My all-the-time "baseline" vision in my left eye, without conscious blinking or palming, is clearly improving. Also no more "red eye"!

If there is interest I can go further into some of the things that I have done/experienced. I hope that all this is of some interest and encouragement to I-SEEers. Best regards,

Ted

An recent article from sci.med.vision...

----- start of forwarded message -----

From: domonkos@access.digex.net

Newsgroups: sci.med.vision

Subject: Re: BILBERRY HERB FOR EYES?

Date: 1 Mar 1996 15:33:02 GMT

Organization: Express Access Online Communications, USA

I'm only aware of it's help in increasing night vision at the retinal level (not by dilation). I take 2 capsules of extract every day, have been now since January. It was less than 2 weeks before I noticed a significant improvement. I'm an amateur astronomer and I have now found that taking 2 capsules 1 hour before I start my telescope viewing has a tremendous effect on my night vision.

Andy

In article <4h5ckr\$p57@cloner3.netcom.com>, jimdoug@ix.netcom.com says...

>

>If the film covering the eye is damaged by cold sore virus
>and needs re-generation will Bilberry be of help and how
>should it be used? Know of anything else to help? It has
>affected the vision...blurry, and am told it needs repair.
>Any help appreciated. Various drops and steroids have been
>tried by the doctor but is getting no better. Thanks, Jim

Dominant Eye

- *Subject:* Dominant Eye
 - *From:* "George Tohme" <PolySoft@msn.com>
 - *Date:* Sun, 3 Mar 96 02:56:48 UT
-

Could someone help me in :

- 1- determining which of my eyes is dominant
- 2- what I should do to make both eyes equal

thanks
george

Cataract operations

- *Subject:* Cataract operations
 - *From:* "George Tohme" <PolySoft@msn.com>
 - *Date:* Sun, 3 Mar 96 03:04:23 UT
-

A friend had a cataract opeartion in one eye about a year ago. Her eye looks quite dark in the centre (to me it seems as if the pupil is wide open) and her vision became etremely bad after the operation which the doctor has labelled `_unsuccessful_` which, according to him, is possible.

My questions are:

1-are cataract operations known to fail?

2-could one person have another opeartion to fix a previously unsuccessful one?

thanks
george

George :

1. Cut a 1" hole in a small piece of paper. Find a small target on the wall several feet away. Hold the paper with the hole in it with both hands in front of your face at arms length. Site the target through the hole. Then bring the paper slowly up to your face. Close one eye then the other and determine which eye is looking through the hole at the target or get a friend to look at you to determine it. This is your "dominant" eye.
2. See a behavioral optometrist who can prescribe vision therapy for you. This can balance out your visual system.

I was left-eyed and right-handed (cross dominant) which some psychologists suggest may contribute to anxiety, uncoordination, and other problems. A psychologist told me the only solution was to change to being left-handed in everything I did! Then I discovered a behavioral optometrist who said I was indeed cross-dominant, but that instead of trying to change my handedness, I could change my "eyedness" (my word)! So I did VT for about a year and sure enough, I was balanced- sometimes left-eyed, sometimes right-eyed. And my binocular vision, depth perception, coordination, etc, etc, improved a lot.

I can only help with the fast and easy part -- answer to No.1. Cup your hands, leaving only a very small opening between your little fingers, bring the "cup" to your face and look through the opening. Choose a point directly in front of you -- it should be the only thing you can see through the opening. Then, without changing your position, try closing one eye and looking at this point with the other one. The eye with which you can still see this point when you close your other one is your dominant eye.

"Dominant" may or may not mean the eye that sees better (people with perfect vision also have a dominant eye, as well as people with about equal refractive errors in both eyes) -- it's the eye that focuses first. I'm curious to find out whether in those whose acuity is different in different eyes, the one that sees better is also invariably the dominant one.

I also am cross dominant (right handed and left eyed). But I've never associated it with contributing to anxiety or with being uncoordinated and problematic. In fact, I thought that I had an advantage in baseball because "I" was a little closer to the pitcher when I batted. (could see "more" of the ball as it was coming). I also shoot a good game of billiards. Have there been studies on cross-dominance (I imagine there have) that would interest me? I haven't thought much about it before but now I wonder what it means to be cross dominant. Are my hemispheres interacting properly? Which of my hemispheres is "dominant"? Does this increase my odds of getting some kind of funky brain disease/deterioration as an old man?

I also am interested in what kind of vision therapy is employed to change "eyedness". And why is changing eyes maybe easier than changing hands (and limbs)?

[snip].

Michael;

You ask excellent questions that I cannot answer right now. It is an area that I was curious about because of my own experiences and the conflicting answers I got from different professionals. I am in the process of learning more about all this, but being only a lowly second year Optometry student, I haven't taken all the courses here yet on these topics. I did work as a vision therapist for a couple of years though (part-time) and have seen people's visual systems balance out and they often become more centered and coordinated (usually kids). But, as in your case, things are never nice and tidy in human nervous systems- they are just too complex. So if and when I learn more, I will get back to you. It seems though, that if you have never had any problems from your cross-dominance, that for you it is highly adaptive.

Herb

Yes, there have been studies targeting vision-related aspects of sports performance. Far as I know, cross-dominance (the term is actually contra-lateral dominance) is an advantage in many sports (like baseball and tennis), a hindrance in some (car racing?), and an irrelevance in some other (swimming?). My own contra-lateral dominance is probably acquired (I suffered a serious trauma to my left arm as a child and ignored my left hand for several months afterwards). As for the rest of the cited psychological profile: I don't see any connection with anxiety; I'm problematic only when I deliberately choose to be problematic; and I'm very well-coordinated. However, I do remember that getting back my coordination (after healing the trauma) was a matter of hard work. In particular, I would get dangerously confused in body-inverted positions when I just started my training in gymnastics. (I later quit for unrelated reasons altogether -- grew up too tall to have any future -- the best gymnasts are shorties, and the very best are midgets).

1) I think we'd all agree Ghandi had attained a very high level of spiritual achievement, along w/ that coming the usual powers of insight, observation (& maybe even occasional omnipotence), right?

2) Ghandi wore glasses, yes?

3) If he wore glasses & he was so enlightened, what's the problem w/ wearing glasses?

this said (in well meant dialectical style) I've been thinking about the analogy between glasses and caffeine, they both enable you to push your body, but they sure as hell are doin some awful stuff to your body.

Anyone have any tips about how to cut down on glasses-wearing time inside that time period in which good distance vision is needed (the front row is still too far away from the board in a required class, etc.)?

(W/ my best attempt yet at the best this world has to offer . . .)

--The Philosopher--

Life is suffering & pain when out of touch with The Great Spirit/Universal ki and your personal ki. Feel through it all with right effort, striving for an ordered soul. Enjoy the beauty of being alive and the power of universal love/loving-kindness in this moment.

Have you washed your bowls yet?

--The Realist--

Work through the "meaninglessness;" just get out and do those activities that you need to do and those that are most meaningful to you mindfully (doing things for themselves sigue Aristotle) and stop thinking so hard about so many abstract and dillusory emotions. Then we can get back in touch first with our "center" and then the universal "center." This notion of centeredness is, after all, pretty darn close to what both Plato and Aristotle were talking about with their notions of a correctly ordered soul.

Have you mindfully done what needs to be done?

```

Well, we've got bits and pieces of that at the I_SEE page. For starters, try the I_SEE mailing list archives...

http://silver.ucs.indiana.edu/~aeulenbe/i_see/maillinglist.html#archives

And look under "environmental influences on vision -- computers and eye strain"

There's some general advice.

One thing I'd recommend is getting a monitor screen filter with electromagnetic field block. I got mine for \$30.

Another thing I'd recommend is a "plus add" -- basically reading glasses for your computer. See under "popular topics -- plus lens therapy" in the archives for details.

The following site has still more information. There's also the following page, written by optometrist Larry Bickford.

http://www.west.net/~eyecare/computers_and_eyestrain.html

I'd take his advice about getting the "full correction for astigmatism" with a grain of salt, since I believe astigmatism is ultimately a muscular problem, and "correcting" it with glasses reinforces that problem. Same for specially tinted glasses -- light sensitivity may be a

symptom of a nutritional deficit.

The following is an excellent book on the subject, a print version of just what you're looking for. It also goes into the "taboo" subject of eye exercises which can help reduce astigmatism.

there is nothing wrong with wearing glasses. but some people dont like
to. some people wish the scientific community would get its finger out
and find a solution to the cause and not a band aid for the problem.

I am also cross dominant in the same way. I have also felt it to be advantageous in some mysterious way. I'm naturally good at shooting rifles (which I haven't done since I was a teenager) and playing pool. I was not so great at archery however, because my archery instructor in college insisted that I shoot left handed. Someday, I'm going to test my theory that I can shoot arrows better right handed in spite of my cross dominance.

A complication is that I do put effort into functioning with my left hand leading to a bit more ambidexterity.

The essential question for me is what is wrong with cross-dominance? Does it really indicate or cause problems or is it just an inherited or acquired adaptive mechanism that has little bearing upon one's functioning in the world?

Regarding my personal experiences with vision self-help, Mario wrote:
".....it would be very helpful/encouraging to many of us if you gave an outline of what your daily "therapy" consisted of. You've given a fairly good description of your progress, maybe you can describe your steps or approach."

First my disclaimer...the basis for most of what I have done is found in Wm. Bates' book. I have no special training, nor have I had professional help, therefore these comments should be viewed as anecdotal only. First of all let me say that I have great faith in one's body to heal itself if the insult is removed. I have always believed that my myopia was not genetic, but induced. I just didn't know how, or how to go about reversing the process. The Bates' book gave me a place to start. The concept that relaxation was the key was a revelation for me. My very first tries at palming convinced me that my eyes were still capable of good vision. This was extremely important to me. I began by making eye charts on my computer and posting one where it could be viewed from 4 feet and another at 10 feet. All my initial efforts were at the 4 foot distance, as 10 feet was too distant. By having these charts in my workplace I could take frequent opportunities to sit back for a moment, palm and use them. What was most helpful? Initially "edging" the letters to get good sharp albeit fleeting vision at 4 feet. But I still had a tendency to strain to see individual letters, so I made a target on the computer consisting of a 2.25 inch jet black bullseye printed on white paper with a 1.5 mm thick crosshairs emanating from the bullseye. I use this at 10 feet by edging the bullseye to sharpen the black disk and the crosshairs. Then I drop my gaze to the chart directly below it. There was immediate improvement. Also, the realization that RELAXING the eye was helpful, allowing me to learn to consciously control that aspect of seeing. Gradually over many months I learned to blink frequently and more naturally to accomplish an immediate sharpening of vision w/o palming. When reading at my desk or at the computer I am very cognizant of the distance from the text, and never allow myself to drift closer (I keep a yardstick within reach). And I always try to maintain the maximum distance that I can read the material. This distance has slowly increased over the months. If the text begins to become difficult to read, I look away, close my eyes momentarily, then begin again at a comfortable distance, and slowly ease the text back out

to the maximum distance I can handle. Lately, when at the computer I frequently look over to the chart beside the window, sharpen that image and then spend a couple minutes looking out at the grounds and activities across the road. I find that this is a great way to get sharper vision at the distance effortlessly. My goal is to get all the relaxed far vision in that I can for retraining w/o any strain. When using the eyecharts with palming or blinking, I have learned to close my eyes while the image is still very sharp and rest them for a moment before opening them and continuing. This seems to let me immediately recover that sharper focus easily. If it "slips", that is if I can't sharpen the image or if I begin to experience strain, I stop and palm for several minutes, then resume. I only do this for 5 minutes or less at one time, but several times daily. All of this is aimed at maintaining relaxation of the muscles of the eye. And as I have said previously, I take advantage of every opportunity to not wear lenses at all.

There is one observation that I have made in my own situation of a habit

that I believe was important in damaging my vision, and that I am actively trying to correct. I have always been a avid reader and am in a reading-intensive profession, and I have found that I read faster by being closer to the text, especially columnated text. When very close-up I can see whole lines at once, and can read very rapidly. But with strain and at the expense of sharp focus and eye movement; that is I tended to stare and gulp text. I seemed to be using peripheral vision to read. I think that this habit was a root cause of many of my problems, including multiple images. Try this for yourselves.... come close to the screen and see how much text on a line you can read...now move back and see that your eyes must track, and focus on individual words to read them. Much healthier. And I believe that this habit even carried over into things like driving. Staring fixedly down the interstate is not nearly as good exercise for eyes as letting your eyes dart all about near and far reading signs, license plates, lettering on vans, etc. And so my "techniques" have centered on using my eyes much more naturally, consciously relaxing them and avoiding strain, and avoiding corrective lenses as much as is practicable.

In regard to questions regarding lifestyle changes, diet etc that I have made, there aren't any really significant things to point to. I have attempted to adopt a healthier diet, that includes less coffee and even more fresh greens and salads. But my diet has been well balanced all along, I believe. And I haven't quit doing artwork or recreational reading, I just give more attention to good visual habits.

Finally, I must state that the exercises I recently picked up on this list have been rewarding already. Especially the techniques of near-far shifting on my thumbs, and using my yardstick to practice focussing/fusion up and down the scale. I appreciate all the interest my posting generated, and hope to learn much more from you all. Best regards,

Ted

-

While I have posted about PRK (laser surgery) and considering it for the future and last recourse, I have been dedicating myself a good deal more at practicing good VT to try and see better. I know that in order for VT to work I must give it my best and believe in it. I think that I am finally in this frame of mind.

For all those of you who have experienced improvements, I ask that you be the judge of what I consider to be my first clear flash. (Actually this may be my second, but the first I dismissed it a while back)

In the book by Jaccob Libberman titled "Take off your Glasses and See", I read about what he calls the wobble on images that we see without our glasses. This wobble is most evident when blinking and looking at light sources. After a blink you will see the light (after a bit of practice) blur decrease and then increase again. The point of this exercise is to get the wobble to decrease the size of the blur (as accomplished by squinting) and not allow it to increase.

Well, one night I had my bedroom lights dimmed and I looked at the reflected light images in the mirror and I practiced this exercise for a while. Without realizing it I dozed off for a few minutes, then I was awakened by my wife as she entered the room. At this instant I opened my eyes and the first thing I saw was the image of the lights in the mirror, these images then cleared up completely like never before. The large blurr decreased very fast until it was gone and only the clear image remained. I must have freaked out because a couple of seconds latter, the image blurred up again gradually and I could not stop it from doing so. I was both excited and then dissapointed. Does this sound like a clear flash? Or am I simply becoming succceptable to all the positive thinking that I've been reading about here? I guess if the latter is true, there

is nothing wrong with it.

I have been wearing my old glasses and that night I had worn my newest (strongest) glasses and then when I took them off my eyes felt very, very strained. As if the muscles on them had been stretched and were now stuck. Certainly, this gives credit to what everyone has been saying all along about what glasses do to your eye muscles.

Thanks in advance, all comments are welcomed.

Mario

Why does there have to be anything "wrong" with cross-dominance? As long as you are aware of your dominance it should be OK. A problem I suffer from I never know which hand, foot, or eye to use in a given situation and have to constantly think about it. If this does not sound like you, than you are fine.

FWIW, some of the greatest left-handed hitters (of baseballs) have turned out to be left-handed and right-eyed. This allowed them to bat from the left side of the plate with the ball in full view of the dominant right eye. Note that in this instance, dominant is meant to be the eye that gives you true position in space, not the one that shifts in the test.

Back to Lurking.....

New Technology, Familiar Problems - Managing Computer and Video Eyestrain

The use of computers and videos is a relatively recent phenomenon and the associated problems of eye strain are now being documented. The kinds of eye challenges we are being exposed to are new. The same eye strain symptoms, however, have been around since the invention of the printing press and the industrial revolution. The use of computers tends to magnify these symptoms, because of the greater demands upon the eye physiology. This commentary will point out a way for you to relax and stimulate your eyes to avoid unnecessary strain and abuse.

The first step is to understand the kinds of symptoms you might experience when you are not paying enough attention to your eyes while looking at a screen. Blurred vision is the primary symptom, which can either be at a faraway distance or while looking up close at a screen or book. Blurred vision could be called a problem. I propose that blurred vision is a gift. When you are driving down the freeway and your generator red light comes on, it is a call for you to do something. In the car, your first line of defence is to pull over to a garage and get your car checked out. For your eyes, it means you are probably overfocusing. Blurry vision, and all the other associated symptoms, are a reminder that you need to do something different with your eyes.

When you have blurry vision, it means you need to change your focus. Here is an effective exercise. Place your thumb in front of your eyes, in line with a distant object. While you look directly at your thumb, notice how much more in focus your thumb appears to be, relative to an object in the distance behind your thumb, at which you are not directly looking. If you are very observant, you may even see two objects the same in the distance. Then zoom your focus to the distant object, and observe how blurry your thumb appears, relative to the faraway object.

Are you breathing while playing this vision "game"? It is normal to find many individuals holding their breath while concentrating on a particular task. While zooming and looking at your thumb, breathe in, then look out and breathe out. Move your thumb to different distances, and experiment with your breathing. Breathe in while zooming out to the distant object and breathe out when you zoom in to the thumb. How do you feel when you zoom? Does your thumb or the distant object appear any clearer or more blurry? Zooming promotes a quick focusing of the eye muscles and reduces blurriness.

Enjoy!

-

Brian Severson asked me to take a look at his web site:

<http://www.sisna.com/vision> because he said he's got something that will help me with my dominant eye.

So I did. Downloaded all the stuff about his vision product kit. Sounds great, but does it work? I'm not trying to put down his product or undermine his credibility or anything like that. In fact, I respect entrepreneurial spirit and good products.

What I would like to do is ask the members of this list to take a look, comment and if anyone knows or heard something about Brian's product to come forward and share the information with us.

And if Brian is around I would like him to give more info on how the product actually work (I'm not interested in trade secret) just more helpful information not just "it's a breakthrough kinda product".

-

This Saturday, I accidentally came across a visual image that has transformed itself into another bit of understanding, close to what Dr. Kaplan mentioned a while back, not as a doctor but as a photographer: the way looking through glasses creates an artistic distortion of the world, in addition to everything else. I was present (in an unofficial capacity) at the portfolio review of the prospective students applying to Mason Gross art school at Rutgers. Mostly the works exhibited were just what they could be expected to be -- students' art of varying degrees of talent and skill. But one Chinese girl's works were strikingly mature and original. One of her paintings showed, in intricate perspective, two hands holding glasses, and the reflection in the mirror of a girl's face caught in the process of putting them on. Most of the face in the mirror is seen by the observer through the (minus!!) lenses of the glasses -- smaller, as if constricted, "pinched" in space -- and only one Oriental eye, young and sad as though facing the karma itself, is seen above the lenses, large and clear. The mirror seems to be about to crack, to fall apart in a kaleidoscope of disjointed impressions. The act of putting the glasses on is seen as an act of self-directed violence, or at least violation. It was really astounding to realize that a single artistic image can give as clear an insight into the heart of the matter as a library of explanations.

Chromatic aberration is due to variation in index of refraction with wavelength (dispersion). If the index were constant with wavelength, you would not have any chromatic aberration. You need the Abbe number of the lens materials or some other way to describe the dispersion of the material.

I think that answers the first and third questions. In answer to the other question, yes dioptric power does affect it (higher refractive power => larger deviations due to dispersion).

Stefan:

I have similar spectacles. I definitely notice chromatic shifts of blue light. I asked the optician when I bought the lenses - she denied that anyone ever complained about it. Truth is, everyone who gets high index notices it; we just decide to live with it.

Unless you demand perfect color balance (for work or hobbies) you will probably get used to it.

I had a different problem too. There are several kinds of high-index plastic; don't accept polyacrylate (acrylic); be sure to get polycarbonate. Acrylic has "orange peel" - bubbles which cloud the lens.

Regards;
Paul Hannan

Hello every expert:

I am a reseacher working with computer over 8 hours a day.
And I got very bad short-sight(-7) when I was very young.

Now I am going to buy a home computer. My son will be
very interested in the education software, and he might have
slight short-sight now. I hope I can protect his eye from deeper
short-sighted as me.

My question is:

What type of monitor is best in protect eye sight? I guess the
monitor of notebook computer (especially active matrix(TFT)) have
no magnetic and electric field compared to most of the CRT monitor,
so that it might be the best one.

Does any expert or experienced person can give any suggestion on
this topic? I have read some articles in the archieve of I_SEE,
but no direct answer.

Many thanks for your kind help!

Xu, Zelin

William Bates did a lot of research in this area and found that spending some time looking off in the distance occasionally was best for preventing myopia. Constant focus at the near "trained" the eye to only focus at the near, which made far viewing impossible and hence led to glasses. (This is a bit of an oversimplification...)

You might want to get a computerized alarm clock so that every half hour or so it reminds him to look out the window for a few minutes at something far away. You might want to look up Bates's book (don't remember the title) or Janet Goodrich's "Natural Vision Improvement". This method apparently met with quite a bit of success in the 1930s and 1940s (if I'm recalling my dates correctly) in elementary schools, but fell out of favor (probably because the teachers didn't want the kids "wasting their time" looking off into the distance :-).

I am no expert, at least not in V.I., but the following suggestions may be useful:

1. Ensure that the monitor you get/ use is a low radiation one; study and compare the technical specifications of the monitors of the available products on the market.
2. Get a monitor screen protector (protector for your eyes rather than the screen)..Glare Guard may be a suitable choice.
3. According to the Bates theory, staring and close work can be particularly strenuous to the eyes..teach your child/ & yourself to periodically (every 5- 10 minutes say) look away from the screen and look at some distant object (after a while it should become a natural relaxing habit)..and do not allow him to use the computer for too long at a time..maximum of 30 minutes should be the very limit; children, unfortunately, are particularly prone to staring.

David.

Re-complexifying Sid's oversimplification, Bates said that "spending time looking off in the distance occasionally" would help prevent myopia ONLY if the object one looked at was small and familiar. Small (in terms of retinal image of course; ie. a sailboat could be "small" if far enough away), because the eye must be forced to focus correctly. If you look at a large object, you don't need the same precision. And familiar, because unfamiliar distant objects induce myopia. In other words, just because you're looking into the distance doesn't mean you're FOCUSING for the distance. And focusing for the distance is what counts. Bates recommended keeping a memorized eye chart on the wall, as the best type of distant object. You could always tell how well your eyes are focused by reading the smallest letters you can. You know what the letters should look like: perfectly black and distinct. If you just "look off into the distance" you can't know whether you're eyes are truly focused for the distance.

Still, looking out the window has its appeal. In keeping with Bates's dictum regarding regarding small, familiar objects, I would suggest looking at the twigs or leaves (depending on the season) or needles on the trees. Or the mortar between bricks in a building.

Hi,

I received in the mail an advertisement for Bilberry capsules from a company called BIOENERGY NUTRUMENTS. Each bottle has 60 capsules of 60mg per capsule for \$13.49 a bottle. They state that they use the form of Bilberry Vaccinium myrtillus (the European form of blueberry). Has anyone heard of or have experience with this company? Is this the right form of bilberry to use? How does the price seem? What about the dosage? Thanks for any help anyone can provide.

Thanks
Mike Sivack

To all,

I apologize for the length of this posting, but I think this issue needs much more attention in the computer industry, education arena, and home.

We have only begun to see the negative effects on our children's eyesight from long hours in front of tiny, fuzzy, wavy, cheap computer monitors.

The sad thing is it doesn't have to be that way anymore. When computers first came out we didn't have much choice...now we do, so there's no excuse.

Enough soap boxing. My direct response follows.

Thanks for hearing me out.

Dave Ducello

I'm not sure i can claim to be an expert on the subject but here are some thoughts for your consideration. I too am a researcher with very short sight (-7.50). I've been using computers extensively since the first ones came out in the early 80's. Because of my eye conditions I've always been looking for what works best. Here are some of the things I've found.

Don't use a monitor with a screen smaller than 17 inches. It should have a .28 or smaller dot pitch. It should have controls for adjusting the picture size, location on screen, brightness, and contrast. The brand name isn't really that important. I've seen some off brand screens that were much better than some of the more expensive name brand screens.

A big consideration is the amount of flicker the monitor displays. You can check this out by looking at a windows screen with a white background. The flicker will look like horizontal waves flowing from top to bottom of the screen. If the screen has much flicker it will definitely drive your eyes crazy. For some reason us folks with high short sight tend to be more effected by this flicker. You may see a flicker that others don't see. No matter, If you see the flicker it's there...look for a different monitor. There are one's available that do not flicker. And don't let some salesman tell you "it will go away after the monitor breaks in". It won't go away, it only gets worse as the monitor gets older.

The most important thing is to try the monitor out before you buy it. I know this isn't always possible, but if you can it will save you a lot of headaches (literally).

Another related item is the video card that runs the monitor. The video card and the monitor work as a team. Get a good high quality video card. Get the card with at least 2meg of video ram. Also look for one that has software that lets you make changes to it's setup easily. You would

be amazed at the difference in readability that a small change in font size or type can make.

I've always considered the monitor to be one of the most important parts of a computer system. After all, if you can't stand to look at the monitor you won't get much use out of the computer. Not to mention the damage to your eyes. Generally, the bigger the monitor the farther you can sit from it and still read it easily. And I think all will agree that it's much better if you don't have to sit to closely to the monitor.

How much to spend? In the United States you should be able to get an acceptable monitor for between 700 and 1000 dollars. A good video card will be about 250 dollars. Keep in mind prices are very volatile so shop around. Whew, that's almost as much the the computer cost! Yup, but what are your eyes really worth to you.

Then there is the question of ergonomics, room lighting, viewing distance to monitor etc. But I think i've gone on long enough for this time.

I commend you for asking these questions. I haven't given you many technical specs to go by because how well you get along with your monitor is a very subjective thing.

Good luck in your search.

-

As I said in my last posting, I am new to vision therapy. I cannot say that I have had clear flashes, just clearer flashes. Is this possible? Also, my flashes or clearer moments are not really flashes that last seconds. I can usually hold it longer than that, through blinking and everything. It is more like my eyes are making a greater effort to focus or the focusing muscle is working harder. Does this sound familiar to anyone? I often experience this after patching. I don't yet patch for long periods of time, I am still getting used to it and am working up my wearing time. So far the longest has been two hours. I find this quite remarkable. I'd appreciate any comments.

Patching for better vision

- *Subject:* Patching for better vision
 - *From:* Alex Eulenberg <aeulenbe@indiana.edu>
 - *Date:* Sat, 9 Mar 1996 10:55:45 -0500 (EST)
-

Carla Wilson posted that after patching, she experiences a period of clearer vision that is marked by a feeling that her "eyes are making a greater effort to focus or the focusing muscle is working harder."

My experience in patching has been that the patched eye feels far more RELAXED and renewed. The difference between the patched and the unpatched eye after I take the patch off is remarkable. The patched eye is the one that improves, not the one that has been "working". In fact, comparing the eyes can be quite distressing. The other day, I used a patch and plus lenses for an hour while working at the computer terminal. When I took the set off, my previously patched eye saw things so much more vividly than the other, that by comparison, the vision in the previously unpatched eye seemed positively cloudy! The effect wore off after a few minutes.

Note that this experience goes counter the standard treatment for amblyopia ("lazy eye"), where the "lazy" eye -- the one that is supposed to improve -- is the one NOT patched. This is not to say that the standard method of treatment for lazy eye is wrong, but that patching may have different effects for different kinds of eyes.

Confronting a Skeptic

- *Subject:* Confronting a Skeptic
 - *From:* Alex Eulenberg <aeulenbe@ezinfo.ucs.indiana.edu>
 - *Date:* Sat, 9 Mar 1996 12:31:23 -0500
-

I posted the the following article to sci.med.vision, misc.health.alternative, and alt.self-improve... "Re: Eye Exercise"

- - - - -

In article <31368477.2B83@chelsea.ios.com>, Mark Simko <msimko@chelsea.ios.com> wrote:
>There is perhaps a seed of truth to the argument that correction breeds
>dependency.

Yes, that wearing glasses makes one see worse without them (or even with them) is a truism that comes up every so often even in optical journals.

For quotations and references, see...

http://silver.ucs.indiana.edu/~aeulenbe/i_see/against_glasses.html

Despite the ubiquity of this anecdotal observation, I am not aware of a single controlled study to find out if this is actually true. Are the eye scientists afraid of the truth, or what?

>However, by dissuading a -2.00 myope from getting glasses at
>least for occasional wear, you are encouraging people to limit ther
>sphere of cognition.

First of all, I am only telling people that others have learned to see better with a weaker prescription, or none at all. And I let them know the techniques that they say worked for them. In fact, many people have reported success with exactly what you are describing -- part time wear of glasses.

Secondly, seeing better without glasses, or with a weakened prescription,

far from limiting there sphere of cognition, rather seems to open up a new awareness to light, form, and color. In eye-reeducation, one must become MORE attentive to one's surroundings, not less.

This theme is constantly coming up on the I SEE mailing list.

For a sample of what I'm talking about, see the letter in the January 1996 archives at:

http://silver.ucs.indiana.edu/~aeulenbe/i_see/archive/Jan/0036.html

> There's too much out there to be missed. Sometimes
>it's life dependant. I personally prefer to have 20/20 vision while
>driving, while New York State only requires 20/40 in one eye! If you
>want to live in a cave, then GOD BLESS!

If you have constructed your life such that you will die without 20/20 vision RIGHT NOW, then well, I guess you're right, you "need" glasses.

However, for a myope (or presbyope or astigmat) to reject glasses does not necessarily mean living in a cave. In many cases, it means coming out of a glass cage, coming to terms with your true visual strenghts and weaknesses, and finally DOING SOMETHING about it.

Let me be perfectly clear. I'm not saying it's immoral to wear glasses, just that if you want to improve your vision without them, you can.

For more on the subject of better eyesight without glasses, see:

International Society for the Enhancement of Eyesight

I completely agree with Alex as I have the exact same experience. But the quick wearing off of the effect is what "troubles" me. 'Cause what patching does is relieve the cilliary muscle(s) so that the lens bounces back from a likely contracted state. So patching has a great preventive effect, in acting towards not allowing a contracted lens to impart some of its "plight" to the axis. But I don't see how patching can help in permanently improving vision.

Each day I get up in the morning greeting the sun and confident that I shall see better this day. Alas, I only need to step out of home to realize that what my mind thinks is not what my body does (in this case). I take it with indifference (a credit to Aldus Huxley, not that I glorify him). Based on my previous successful handling of power increases (i.e. through constant plus lens therapy I did not allow a decrease in acuity) I tell to myself that if my eyes don't get better by themselves, I'll up the power. I feel completely relaxed most of the time. The result so far (after nearly six months) - statistically insignificant. I concur with the notion that the refractive state of the eye is dynamic. There are two questions to this, though. First, is this dynamics both ways? And second, to what extent? I am fairly sceptic on both. On the first, yes, temporary turning into permanent if you don't counteract in time (on the worsening side), and almost always only temporary (on the improving side). On the second, infinite on the worsening side, little (2.0D max and mostly temporary) on the improving side. Btw, it is well known that with aging some eyes tend to become less myopic. Antonia Orfield's reportedly

successful 7-year vision quest may well have coincided with this process (I think she was in her late thirties/early forties during that time).

Alex,

In reply to your questions, I hope this information is of help and maybe clarifies what I explained in my last posting:

I am nearsighted, about -6.5 in one eye and about -7 in the other. I have been wearing glasses/ contacts for about the past 15 years. I have been wearing them 100% of the time for the last 10 years. I am told that I have a slight astigmatism, but not enough to bother correcting. I have never noticed it as it only affects my far vision slightly.

I am a teacher (French immersion and ESL).

When I said that my eyes are making a greater effort to focus, there is no strain involved. It is honestly as if my eyes are focusing. Sometimes an image will be a little blurry at first but after a couple of seconds gradually come into focus. The feeling in my eyes is a little different, but not in a bad sense. I would liken the experience to what one maybe undergoes during physiotherapy where one is regaining control or strengthening a specific muscle. I would say that my eyes feel more relaxed than at other times. That's about it.

Carla

>Carla, can you provide the following information:

>

On Sun, 10 Mar 96 11:01:14 HKT,
Ashwin Panjabi <ashwin@asiaonline.net> asked:

> What is patching anyway?

Patching means covering an eye with a patch. The optometric term is "occlusion". Patching's most widely-known and accepted use is as treatment for lazy eye, where the good eye is patched, and the "lazy" eye forced to work. Bates, however, recommended covering the eyes (with the hands, though) as a way to help rest and therefore improve the vision in the COVERED eye. There are many possible reasons why a patch is helpful therapeutically, and there are some instances in which wearing a patch is detrimental (e.g. covering an amblyopic or "lazy" eye full-time). When in doubt, consult an eye care practitioner about the safety of your using a patch.

One book that heavily emphasizes the use of the patch is "Eye Power" by Ann Hoopes. Another is "Seeing Without Glasses", which mentions a special kind of patch, called a "binasal occludor" which is worn on the nose and eliminates the need to converge the eyes for single vision. I have found that the "binasal occludor", while absolutely ridiculous looking, can be very beneficial in improving 3D perception (once it's taken off).

For previous posts concerning the uses of a patch, search for "patch" in the following archives...

Looking at the mortar between the bricks in a building is a good way to measure how relaxed your eyes are.

I find that I can see to horizontal lines of mortar blurred but quite easily. As to the vertical ones, they're more difficult to see (of course it depends on how far the building is) but will come into focus when the eyes become more relaxed.

There is a very practical side to this, as well as the philosophical one. Since I started using reading glasses over the last 18 months or so, (having been glasses-free since I gave them up at 16 or so),

I have found that in spite of all the care I seem to take, they always end up getting scratched. As well as that there is the constant need to keep the things clean and smear-free, etc. I sometimes find myself taking them off to get a clearer view of the world, even if optically I am having a slightly harder time of it by so doing. I think I would rather put all the time and resources it seems to take to keeping my glasses in running order into getting my eyes back into better condition.

It's not to say it's right either. As far as I can tell, it never worked
for me, but I was very young at the time, and can hardly remember details.
(I suppose it's possible that the treatment made my condition less bad,
without actually "curing" it).

Having tried it again as an adult (i.e. patching my "good" eye), the
effect is approximately:

Lazy eye: It appears that the brain begins to relearn to use this eye to some extent. In my case, because my eyes are out of alignment, this tends to cause double vision, and so the brain tries to suppress the image again. Result: confusion and possible strain.

Good eye: Because it has been patched, relaxed and rested (as Alex says above), the image that it offers is much clearer, sharper, vivid etc, contrasting with the indistinct image offered by the lazy eye. This tends to reinforce the suppression of the image offered by the lazy eye.

Conclusion: It's sort of back to square one; I don't think it works. I don't think it can ever work. I have yet to meet anyone for whom it worked.

Mike.Ellwood@rl.ac.uk

(presbyopic amblyope, and friendly skeptic towards VT).

Does anyone know of any work involving hypnosis as a way to reduce myopia?

I just remember reading something about that but I can't remember where or what.

Sorry for the belated response. I hope this can be of some help.

I have a brochure about Bilberry capsules from a company called Natrix International, LLC (based in Boulder, CO). They offer "Bilberry 2020 Optometric Nutrition Formula" from Advanced+Botanics (A+V is probably another company).

Natrix claims that their bilberry is processed by Indena, a leading European nutraceutical firm. I didn't order because I had bought multivitamins in the meantime. You could call Natrix at 1-800-586-7771 and compare prices and dosage.

- *Subject:* Re: Hypnosis & Myopia
 - *From:* "Linda Lee" <llee@comox.island.net>
 - *Date:* Tue, 12 Mar 1996 00:29:22
-

George,

a couple of years ago, i signed up for a series of six hypnosis sessions. My goal was to reduce my myopia, or at least understand it better.

The therapist didn't have an understanding of VT but she was willing to give in a try as she had worked with other alternative healing models. At one point, she did ask me to go back to the moment i decided to become myopic and i did give her an answer. I have no idea if my answer was accurate - it didn't feel like it was - nor was there any great insight achieved from 'knowing'.

My own experience was not valuable to me and i won't undergo hypnosis again. I personally had no results from it. It was interesting tho as i had never been under before. I found it very much like meditation but i didn't have to take myself down. If you haven't tried meditation, you might want to give that a whirl. It is very relaxing and free. I may have had improvement when i began meditating but it's difficult to say because i started VT at about the same time.

Good luck.

Linda Lee

Does anyone know if bilberry leaf (as opposed to fruit) is good for the eyes? I think it was discussed a while ago but I seem to have missed the outcome of the discussion. I have ordered a pound of dried leaves for \$17.95 via a local health food store (I can find out the name of the company) and have to say that, one, it's a LOT (will probably last me for many months), two, it's the real thing (I used to gather wild bilberry in Belarus and Lithuania and steep fresh leaves for tea, so my palate can readily recognize it), and finally, the tea is delicious. But I don't know if what it's supposed to do for the eyes can be derived from the leaves. Please enlighten.

Elena

I have read of a few cases regarding hyp & myopia. In the first case a lady had had a traumatic experience as a girl (car accident and she saw someone die or something to that effect) and she developed myopia. In the second case I read a reference of myopia (certain cases) being caused by tight ciliary muscles, hypnosis was used to relax such muscles....

Very good question George. I was wondering this myself. If myopia is a stress/emotional/psychological/mostly-in-your-head induced disorder of our visual system, then I would guess that hypnosis should work. Of course there's the other ifs, "if you believe in hypnosis", "if you believe your myopia is curable", "if you know a hypnotist that knows what they are doing regarding VT", etc.

I second his question.

Mario

Mike...I have been buying Bilberry from two different sources who are considerably cheaper than the one you are quoting...

I and my wife have now been taking bilberry for 6 or 7 months with very satisfactory results. I might state that it seems that all of the bilberry available is of the myrtillis type so this statement is no big deal... There appears to be two types available, the powdered berry and the dried extract type. We started out on the dried berry type with good success, then I found a source of the extract type at about the same price so we are now on it. Which is best?, we have found very little difference, but since most of the reported research was done on the extract type, I plan on staying for a time on this type..

The difference in the quantity of the capsules at first bothered me, since the powdered berry type usually contains around 360 mgs while the dried extract type are around 60 mgs...Then it finally dawned on me that they were probably equivalent in the key component that they both stress..

We started out taking three caps a day, and have now cut back to two, with and occasional failure of even this amount. It seems that we are sustaining the beneficial effect that we first discovered.

The following two vitamin suppliers are the most reasonable that I have found:

BRONSON Vitamins and Herbs
1945 Craig Road, PO 46903
St. Louis, MO 63146-6903
For Call in Orders: 1-800-235-3200

They have the extract type which lists at \$9.43 for 100 caps of 60 mg.

Puritan's Pride
1233 Montauk Highway

For Call in Orders 1-800-645-1030

They have the powdered berry type which at present with a special sale going on lists for: 5 bottles for \$56.00 for 100 caps of 375 mgs..

The very real problem that I have with all this material is that there is no Agency that oversees the gathering and preparation of these herbs, which means that we are depending to the hype put out by the suppliers which I have never found to be too reassuring..But for now I am feeling good about the results so I wont be too critical..But I am keeping a very close lookout for any undesirable side effects which may become noticable..

Hope this answers your question.. Roy Kopisch

I seem to recall that the components for helping the eyes are in the fruit.
The leaves are indicated for treating blood sugar imbalances (eg. diabetes)
and some other conditions, although you have to monitor dosage carefully.
Try doing a Lycos search for bilberry, I did that a couple of months ago and
got some really good information on bilberries (almost more than I wanted to
know!).

Could someone please tell me if they know of an herbal, nutritional, homeopathic, or other natural remedy for pigmentary dispersion syndrome? I realize that this has nothing to do with myopia reduction, but I do think it has to do with vision. The pros at my optometry school here say there is nothing to do be done for this and I just found out I have it. It leads to glaucoma in 10% of cases and my IOP's have risen to a near borderline level in the last year, so I would lime to do something if possible. Any info would be appreciated.

Yesterday, a three demensional bubble, about half the size of a pea developed in my right eye. The bubble is clear except the edge on one side is black.

The bubble is not in my central vision -- but about 3/8th of an inch above it and to the right.

The bubble does not float, it follows my visioin.

Does anyone have an idea what that may be?

Apprrciate any response.

Bill,

go see an ophthalmologist (preferably a retina specialist) PRONTO. May be nothing, may be retinal detachment -- if the latter, the earlier it's caught, the more successful is the treatment. (Early may mean within hours of the event). Again, may be nothing... but sounds like a good reason to find out ASAP.

I think that myopia is GREATLY affected by the brain especially during intensive VT ie. during exercises, relaxation and not wearing glasses.

So that was why I thought about Hypnosis (I'm actually studying Psychology but have not tackled hypnosis).

1- I do believe that hypnosis is real and is usable during therapy ie. not some mystical power that some people possess.

2- I do believe that myopia IS curable. I actually have no doubt about that.

3- I do not know a hypnotist but I'm looking for one.

Whatever I find I will posted on the list.

george

George - Hypnosis is a real effect in which the mind is very relaxed and open for suggestion - there is nothing mystical about it. The question is whether one is a good subject for it.

On this subject, you might like to check out the NLP (Neuro-Linguistic Programming) book "Frogs into Princes", by Bandler & Grinder (psychology section in bookshops).

Basically, NLP says that you can re-create any 'states' (configuration of muscle position, etc) you've had in the past, and since you once were in a 'state' where your eyesight was good, you should be able to access it again. At one point in the book, this is mentioned, and a story recounted in which a patient was asked to remember his childhood and, upon returning to the present, told to retain the physical state of the eye as it was when he could see properly.

Good results: his eyesight became excellent immediately, although it later gradually returned to it's old myopic state. This, I suppose, might be due to him still using his eyes in the old, squinty, unrelaxed way he always did, rather than maintaining them in the relaxed state.

....and, hey, twenty years of hard-learned myopia is a real wrench to give up, isn't it?

Anyway, worth checking out I reckon...

Paul.

Results of the second month

- *Subject:* Results of the second month
 - *From:* "George Tohme" <PolySoft@msn.com>
 - *Date:* Sat, 16 Mar 96 06:09:35 UT
-

Hi,

this morning I went to see my optometrist for my monthly eye exam. The results were not what I expected there was no improvement nor deterioration from last months.

So, here's what it looks like:

18/1/96	L: -3.00	R:-3.75
18/2/96	L:-2.50	R:-3.00
16/3/96	L:-2.50	R:-3.00

My current prescription glasses are still: L:-1.75, R:-2.00

I don't think that today's results are accurate for three reasons:

- 1- The test was at 8:30AM which I think is too early for my eyes
- 2- I did not sleep well during the night
- 3- I can see a difference in my vision: I can read signs on buildings that I could not read before

My eyes performance was sort of 'shaky' because I could not consistently see with -2.25, -2.75 which is what I expected the results to be.

I asked him for a VERY weak prescription for computer work because I don't need all the extra power of the above prescription. So now I have an extra pair of L:-0.75, R:-1.00.

Next time I will have the exam at around midday and make sure I get enough sleep the night before.

Many thanks to all of you for your support.

george

Hi George.....

You asked as to what I had expected from the Bilberry? I had very little expectation but a lot of hope. For 17 years I have been fighting a terrible vision problem which started with the installation of two highly experimental interocular lens in my eyes 18 years ago. These were of the strip type with two points on each end and were implanted into the flesh within the eyeball and cannot be removed and replaced without major surgery, which after the pain of installing them I refuse to do.

Both lens have irregularities that distort or block my vision in spots.. I have tried every thing that I thought would improve my vision so that life would be more normal again... I have been able to protect fairly well the basic mechanism of the eyes but trying to improve my vision has been a constant fight...and up to now I have found very little help.

Even though nothing is going to correct the interoccs, Bilberry has provided me enough vision improvement that I am happy so far with the results...

I am going to paste at the start a post I made to Kellie Cass on 8 Sept 1995, which will prepare the ground for an up to date assessment. This I had to copy from Alex's fabulous Home Page library since I had not kept a copy of it. I have edited it slightly to get rid of some of the extraneous information.....

Kellie

Your comments on bilberry tea intrigue me. I have never considered the tea, probably because I have never seen it advertised.. My wife and I are taking the 375 mg capsules, which the bottle states may be opened into a glass of warm water to make a tea. But the capsules are so easy to take, why go to the trouble.. From this labelling I assume I am taking the crushed leaf type.. I am checking around to see if I can find the extract type as it seems most of the medical research has been done using the extract. I am finding it very difficult to find out any trustworthy facts on the bilberry that is available. The recent report made available here, written by Paul Bergner, stated that one type of leaf had a detrimental effect on the liver. The type that I trust the herb sellers are putting out is the "Vaccinium Myrtillus" or more commonly referred to as V Myrtillis.. This Type appears to be the only type that has been researched..

You are right that it is rather expensive, as the first bottle I bought at the local vitamin dispensary, that I am on the least precarious belief level with, cost me twenty dollars for 90 capsules. I have since found a catalog sales outfit that during a special sales period, allowed me to get them for ten dollars per 100 capsules. We started taking bilberry about two months ago with very satisfactory results.. and now plan on giving it at least a 6 month trial. We started by taking 3 capsules a day for about a month, then noticed as researchers have noted that we were both

feeling the diuretic effect of the bilberry so we have cut back to 2 a day and seem to be getting the effects we wanted on our eyesight..

As for concrete results; I had my regular eye exam about a month after we started the bilberry. I have an exam every four months because of a 15 year battle with glaucoma. I got the lowest pressure reading on both eyes, that I have recorded over the past 3 years. Not by much, but the lowest reading in three years and I was shocked because the only thing I was doing differently was the bilberry.. I had the tech double check since I have had wrong results before, But he duplicated the first results so for the time being I have to assume they were accurate. The next check a couple of months from now will be the clincher, I hope. My wife who has no glaucoma problems went for her normal yearly checkup and asked for a new prescription so she could get her old glasses replaced.. When the the lady that was measuring up her eyes for a fit of the new glasses, looked at the data, she acted very surprised and blurted out "Your eyes have improved since the test you had 2 years ago". Eyes of people your age don't improve but deteriorate a little year to year. (Our age is a secret, but we did both retire a number of years ago.)

Our personal observations are; I am not wearing my glasses around the house, which I have had to do for many years. I use a set of reading glasses occasionally, but find some times I can read comfortably without them. This is a new and novel experience. I have set up an eye chart here in our computer room, which allows us to make random checks, and my wife has noticed that her eye that does not have an interoc in it, but does have a developing cataract, is reading the chart better.. I don't know whether this can be ascribed to improvement in the cataract or to improvement in vision intensity.. Time must pass before we know.. Hope this rather lengthy letter may allay some of your apprehension and prove to be of some help to you

That was written 6 months ago and at that time we had been taking the bilberry for 2 months, so now I can comment on 8 months of bilberry use.....

First,, it did not help my eye pressure. I have had two routine checks since then and they have shown a rising trend. I am just a tad concerned about this as the last pressures were around 25 in both eyes and that is about 3 points higher than I normally will average. If I find that the next

pressure shows a continuing rise I will stop the bilberry and see if that was the cause..(I am also being more faithful with eye drops twice a day).

The visual improvement which I noted is still present, but at about the same level as it was at the end of two months.. This improvement depends on a continuing use of the berry because a few day lapse and the deterioration becomes noticable..Sometimes the vision effect is even more transitory and only lasts a few hours ... But the improvement is actual. I have quit wearing my glasses when I am out doors.. Not that my vision is good, but it is better than we were able to do with corrective lens.. My last eye exam I insisted on taking without glasses, after telling a very disapproving eye intern that I no longer used the glasses.. My left eye checked a 20/30 and the right eye a 20/70..Thats not too good, but it is not bad compared to what I have put up with the past 15 years.. I feel better about driving than before and it is nice to not have those glasses hanging on my nose which they did for the last 60 years.. One of these days I will break down and get a new prescription to see if a further improvement can be made..

Now my reading vision remains good, although I have bad days that required me to reach for the magnifiers.. It seems strange that I can read the smallest print on the reading eye chart that they hand me but newspaper print sometimes is difficult to make out clearly..

My wife continues to find the original improvement, but she is most excited about her improved night vision.. She does some night driving which I do not and she gets quite excited at times how well she sees during this night time driving... She has had no further eye exams so actual data of improvement is not available....

Now a comment about my daughters experience..She was complaining in her E mail about how tired her eyes were after hours of staring at a 14 inch monitor at work.. I sent her a couple of bottles of Bilberry and enclosed some literature, since she never believes me... She would occasionally mention that she felt the bilberry was helping..I wasnt sure but what she wasn't just being polite about it. Until a letter came wanting to know where she could order some bilberry. She had ran out and within a few days her old problems were back and she noticed that her driving vision was not as good. .

George I wish it was possible to say positively that bilberry is the end all, but practically all my data is subjective and not measureable.. I am happy though at this point with what the bilberry is doing...But still on guard against undesirable or potentially dangerous side effects...

Regards, LeRoy Kopisch, Sun Lakes, AZ

And Alex, if you happened to have read along with us down this far, My sincere congrats to you for one of the finest Home pages I've seen.

aka Ole Roy

Most print is too big for your eyes!

- *Subject:* Most print is too big for your eyes!
 - *From:* Alex Eulenberg <aeulenbe@indiana.edu>
 - *Date:* Sat, 16 Mar 1996 18:49:11 -0500 (EST)
-

Reading, the way it is typically done, is a very poor activity for the practice of acuity, even near acuity. The standard for 20 feet (the "20/20" row) is a letter 9mm tall. So what would constitute the same acuity standard for the near point? This is easy to calculate: "relative size" is proportional to distance. Assume a reading distance of 1 foot. Since this is 1/20th the distance of that to the wall chart, the corresponding standard is 1/20th of 9 mm or less than a half a millimeter(!), for the size of a letter at 1 foot!

That's right, the letter on the 20-line of your eye chart produces the same size image on your retina, when viewed from 20 feet, as does a 0.45mm image when viewed from 1 foot. Incredible! I think this is about the size of type on microfiches.

Does this sound a little small for you as a standard type size? Well, maybe it would make more sense if we had a 2-foot, instead of 1 foot standard.

So what if you hold your text at 2 feet? Well if you double the distance, you're doubling the size of the standard but twice a size less than half a millimeter is still less than a millimeter! Can you imagine reading millimeter-size type at 2 feet?

Well, OK. Maybe it is too much to demand 100% acuity for all of our reading. Let's reduce our 2-foot acuity standard by a half, that is, double the size of the letters: 2mm type for 2 foot reading. Let this sink in: If you read at 2 feet, which would never be considered "abnormally close", reading a 2mm type size is using HALF the normal visual ability, in other words "20/40" vision. However, typical type is about 3mm tall for the smallest lower case letters. Thus reading requires only "20/60" vision IF done at 2 feet. Someone who reads at a distance of one foot, then -- not too uncommon -- is only exercising their acuity at a level of "20/120"

vision, or one sixth the "normal" capacity!

Thus we see that limiting one's primary visual input to reading books not only means underutilizing one's powers of distance vision acuity in particular, it means underutilizing one's powers of acuity in general.

There is no reason to think that reading smaller letters should cause strain or myopia. The finest of fine print can be viewed from a reasonable reading distance given an eye with normal acuity. On the contrary, reading fine print gets one in the habit of attending to fine detail.

These considerations have much to bear on the idea that reading leads to myopia. Is it really through over-exertion of the ciliary muscle? Or is it more about a loss of appetite for acuity?

More later.

--Alex

> refuse to do.

OK. Your lenses have been removed. So according to the standard theory of how the eye works, your eyes should not be able to adjust to distant objects at all, since it is supposedly the lens that changes during accommodation.

> Our personal observations are; I am not wearing my glasses
> around the house, which I have had to do for many years.
> I use a set of reading glasses occasionally, but find some
> times I can read comfortably without them. This is a new and
> novel experience.

Yes, as a matter of fact, your experience is contradicting the textbooks.

> I have quit wearing my glasses when I am out doors.. Not that my vision
> is good, but it is better than we were able to do with corrective lens.. My

Now perhaps you know why the intern was so disapproving. How dare you break a law of optics!

> My left
> eye checked a 20/30 and the right eye a 20/70..Thats not too good, but

> it is not bad compared to what I have put up with the past 15 years..
> I feel better about driving than before and it is nice to not have those
> glasses hanging on my nose which they did for the last 60 years..

60 years! As I said, it is against the laws in the optics books for you to be able to see clearly at various distances without glasses. You're supposed to have no power of accommodation, first of all because you're over 40 (you're supposed to need reading glasses or bifocals), and second of all your lenses have been removed, for crying out loud!

> One of these days I will break down and get a new prescription to
> see if a further improvement can be made..

>
> Now my reading vision remains good, although I have bad days that
> required me to reach for the magnifiers.. It seems strange that I can read
> the smallest print on the reading eye chart that they hand me but
> newspaper print sometimes is difficult to make out clearly..

Now is the newspaper print difficult to make out because it's small (thus challenging your retinal sensitivity), or because it's close (thus challenging your power of close-focusing)? You can check this by comparing your ability to read small print up close versus your ability to read the "small" (although larger by absolute measurement) letters on the distant eye chart. "Relative size" is proportional to distance, so it's very easy to calculate. For example, a 3mm object viewed at 2 feet requires the same resolving power of the eye as a 30mm object viewed at 20 feet (both measurements increase by a factor of 10).

This may be for several reasons. First of all, if you look with each eye separately, it takes less mental control than if you use both eyes at the same time: when you use both eyes at the same time, you must constantly keep them in alignment. Usually, they test one eye at a time. Secondly, even if you can manage to align your eyes for the binocular close vision test, your eyes may tire and go blurry after a long stint of reading, or when you are otherwise fatigued. Exactly what "tires" I'm not prepared to say. It could be the retina becoming devitalized, or astigmatism caused an uneven pull of the fatigued extraocular muscles, or both, or even sluggish circulation causing a cloudy buildup in the humors of the eye. What I do know is that often, simply resting the eyes by closing them for a few minutes will bring back some clarity and especially intensity of color whenever my vision degrades. "Trying to focus on a distant object" for the purpose of relaxing the muscles of accommodation may help, in certain instances, but if you "try" too hard, this can cause even more eye strain. In the case of someone whose lenses are removed, of course, your muscles of accommodation aren't "supposed" to be a factor anyway.

So suppose you have determined that the a close up object is in general more blurry than a distant object of the same relative size, indicating

that the blur is the result of a failure to shift focus, and not a result of a general "low resolution" of your retina. In this case, close vision practice should be of benefit. However, you say that you have artificial lenses, and removing the lens is supposed to eliminate the ability to focus completely. According to the textbooks, you should no more be able to focus your eyes than a Captain Hook would be able to clap his hands. However, this is just what they teach in the textbooks. See my next post for details on a way to improve one's ability to shift focus from far to near.

Eye Exercise: Near-Far shifting

- *Subject:* Eye Exercise: Near-Far shifting
 - *From:* Alex Eulenberg <aeulenbe@indiana.edu>

-

Here is a practice routine `_anyone_` can use to improve their focusing ability. It is method found in William Bates's classic "Better Eyesight Without Glasses".

Materials:

- 1) Newspaper (or other source of fine print)
- 2) Snellen Eye chart. If you don't have one, you can download one from...

http://silver.ucs.indiana.edu/~aeulenbe/i_see/eyecharts.html

Method:

Practice first on one eye, then the other, then both together. If closing one eye is uncomfortable, you may find it easier to place one hand over the eye. A "professional" patch is available for about \$3.00 at the drug store. A bargain, I must say.

- a) Hold up a newspaper so that both the letters on it and the eye chart in the distance are in your field of vision.
- b) Direct your attention to a letter in the newspaper.
- c) Now look at the same letter on the eye chart. Notice that the letter on the newspaper becomes less distinct, while the letter on the chart becomes more distinct.
- d) Now look back at the letter on the newspaper. Notice that it becomes more distinct, while the letter on the chart becomes less distinct.

NOTE: As you shift focus from the easier-to-see letter to the harder-to-see letter, keep the image of the clear, black, letter in mind. Imagine that you are actually seeing this letter instead of the letter at the other distance.

If this is done successfully, the vision for both letters will improve. If you experience strain while doing this...

a) Take a break by closing and covering your eyes (palming). As you do this, imagine the letter that you have been practicing on as if it were perfectly black and distinct. If this is done successfully, your actual vision will improve also. However, if imagination proves difficult, simply let your mind wander and see whatever comes to mind.

b) Vary the distances of the newspaper and the eye chart to your eyes, and vary the size of the letters you look at.

 - *From:* "Linda Lee" <llee@comox.island.net>
 - *Date:* Sat, 16 Mar 1996 22:08:02
-

To the I_See group:

About 10 days ago, i received my Vision Freedom kit from Brian Severson and have been following the plan for 8 days. I thought the group might like to know of my progress.

It seems to be working. I am spending at least 2 hours a day doing the one reading exercise, so far without the plus glasses. My vision is about -5.5 in both eyes so i have enough difficulty reading close up without adding the extra burden of the plus glasses. I gather they are to be used when i can read print beyond arm's length.

The results i have achieved so far are:

Originally the distance from my nose to the book was 17 cm and now i can focus print up to 26 cm away. I don't know if a 9 cm (3.5 inch) increase is significant but i consider any improvement important.

My distance vision is not so easy to measure. With -5.5, it is not really possible to focus even on the largest letter on a chart at 20 feet, or even at 10 feet. I do know that my vision through my 50/20 transition glasses has improved. I can now see at about 15/10. My own estimate is that i have improved by about -.75 diopters.

I feel that the program is working for me. I found the booklet easy to understand and his explanation for recovery is simple -- if you encourage your eyes to autofocus (i.e. don't make the effort impossible) and do it often enough, the muscles will strengthen sufficiently to change the shape of the eye. I don't find the 2 hours daily exercise excessive, but then i work at home and reading is a big part of what i do anyway. He mentions that people often get headaches when they start but i haven't.

I know that one of the most important ingredients in any recovery process whether it is physical or psychological is to have a plausible explanation. I don't know if this is medically possible or not, but it makes sense to me so i plan to stick with it.

I'll let you know what happens. I usually test myself on Saturday so i'll keep you all informed.

Linda Lee

Excellent, that's EXACTLY what I'm looking for!!!!

I have not thought about NLP because the stuff that I read about it confused the hell out of me. My first exposure to NLP was reading and listening to Anthony Robins which didn't help clearing up what NLP is. Subsequent articles made it even worse and to me, it seemed to be som many things.

I will give the book a try and let me know if you have any other recommendations.

thanks
george

>So that was why I thought about Hypnosis (I'm actually studying Psychology but
>have not tackled hypnosis)....

On this subject, you might like to check out the NLP (Neuro-Linguistic Programming) book "Frogs into Princes", by Bandler & Grinder (psychology section in bookshops).

Basically, NLP says that you can re-create any 'states' (configuration of muscle position, etc) you've had in the past, and since you once were in a 'state' where your

eyesight was good, you should be able to access it again. At one point in the book, this is mentioned, and a story recounted in which a patient was asked to remember his childhood and, upon returning to the present, told to retain the physical state of the eye as it was when he could see properly.

Good results: his eyesight became excellent immediately, although it later gradually returned to it's old myopic state. This, I suppose, might be due to him still using his eyes in the old, squinty, unrelaxed way he always did, rather than maintaining them in the relaxed state.

....and, hey, twenty years of hard-learned myopia is a real wrench to give up, isn't it?

Anyway, worth checking out I reckon...

Paul.

George, and everyone

I know how disappointing it is to be feeling very good about the work you have put into VT and then not see the results in the doctor's office. I have heard that there is a method for getting around this.

Get there early and / or do some exercises before you go in for the exam. I think it is very important to have both eyes measured at the same time - the doctors know how to do this but for some reason they prefer to examine each eye independently, even tho we don't use our eyes that way.

Don't wear your stronger glasses that day, ie, your regular 20/20 prescription and tell the doctor to begin your exam with plano lenses and work up. Apparently when your eyes see strong lenses, they revert to their 'flabbiest' position.

Personally, i don't bother with eye exams much anymore as a method of determining improvement. They are not definitive and yet they feel as tho they are, and so can be very discouraging. The only time i see the doctor is when i feel disoriented and sick when i wear my glasses. Then i make sure she does all the things i have described above.

The only way to reach your goal is to keep reaching for it. Chin up soldier -- we're all rooting for you!

Linda, you are right to consider your "9cm" improvement important. If you can focus clearly only up to 17cm, you have $1/.17 = 5.88$ diopters of myopia. This is consistent with what you say about your prescription of -5.5. Being able to focus absolutely clearly at a maximum of 26cm = $1/.26 = 3.85$ diopters of myopia. Thus, your improvement is a difference of two diopters, or 34% of your myopia! Realize that a person with "only" one diopter of myopia starts seeing things blurry at one meter!

You probably mean 20/50 and 10/15 respectively. Remember, the distance from the chart goes on the left, the number on the smallest line of letters you can see goes on the right.

> My own estimate is that i have improved by about -.75 diopters.

Well, as I just said, according to the laws of optics, you have done even better than that -- if the letters that you now see at 26cm are as "perfectly" in focus as the ones that used to be your distance maximum at 17cm.

I would suggest that you measure your distnace acuity also without glasses. As I disucussed in a recent post, if you double the size of a letter on your chart, you double the distance standard for that letter. So if the largest letter on the chart that says "70", double its size and you will get a "140" letter. Quadruple the "50" letter and get a "200" letter, and so on. These enlargements can easily be done at a copy shop.

Yes, this refers to suggestions from the archives of this newsgroup.
No eye doctor - I get my eyes checked every four years at the motor
vehicle bureau. #;-)> So far I don't need glasses to drive (but it has
not been easy to pass the exam). One concern is not to accelerate
becoming presbyopic. But according to an article last year or so in

Scientific American, it is unavoidable.

>changes. A doctor recently posted about his experience as a farsighted
>person, after wearing the same kind of "plus" glasses, becoming even
>more farsighted after prolonged use, just as you and I become [temporarily]
>less nearsighted.)

I don't understand it either. Perhaps the eyes are attempting to
focus beyond what would normally be "infinity"? It's a mystery they
know what to do, being temporarily "fooled" by the glasses. Is it just
an accident then that they wind up better focused for distance? I
mean, why don't they focus better on their own? This shows that they
are able to do it with some prodding.

>>But I would like to make sure sure that they are optimal and also to
>>extend the concept to reading the newspaper. This is where I have
>>trouble adjusting to the larger type.

>Sounds like you're saying the glasses magnify the type, which is what

I would like to avoid the magnification. Should I try to get a weaker
pair, say +1.0?

>But "optimal" depends on the purpose to which you wish to put the
>lenses. Are you trying to stave off myopia, or does reading give you
>eyestrain when you don't use glasses?

I learned (from Bates) that relaxing improves my vision much better
than straining to see. So eyestrain has not been a problem. (Not
counting overworking the eyes by too much close up work.) My
near-focus(?) is very good without glasses. Using the reading glasses
quickly improves my far-focus(?). If they neutralize the effects of
close up work, then that would be a reason to use them. But if they
somehow reduce my eyes own adjusting capacity then they would not be
worth using over the longer term.

>>Also at this distance, the images from one eye are not
>>as clear. (Could this be astigmatism?)

>I bet it's just that that eye is more myopic. With your glasses off, if
>that eye sees worse for distant objects but they both see the same for
>near objects, that would explain it.

You're right, this is the more myopic eye. What surprised me is that
(moving over 2 feet away wearing the reading glasses) one eye sees the
print as something like "italics" but not necessarily out of focus, if
you know what I mean. At any rate, this seems to be a "hard" error,
one that will not change(I could be wrong about this).

>>The (Dollar Store)glasses were
>>marked with a +1.5. Other pairs had an additional number on the

>a focal length of $1/1.5 = .66$ m. If your eyes can focus perfectly for
>infinite distances -- if you can see the man on the moon in crisp detail
>-- this means you can see clearly through a +1.5 lens up to a distance
>of 66 cm. Another way of saying this is that the lens simulates infinite
>distance at 66cm. The higher the number after the +, the closer you
>bring your distant blur point. But you could have figured this out
>by trial and error at the Dollar Store.
>--Alex

A while back I bought the strongest pair (~+3.0). They work well for
very close up work like under the car, where I can't get further away,
and as a magnifier. They get blurry(for me) at about 10 cm.
I still don't know why some had a "bottom" number but others with the
same +X.xx did not.

As far as using a weak pair for reading, would I be better off
combining the lenses from two pairs to match my myopia in each eye?
Also should I be concerned that the vision in my better eye
temporarily improves more than the other and becomes more "dominant"
at the time? I get some indications of this. Bob B.

Accomodation exercise with pinhole glasses

- *Subject:* Accomodation exercise with pinhole glasses
 - *From:* "George Tohme" <PolySoft@msn.com>
 - *Date:* Mon, 18 Mar 96 02:35:52 UT
-

last week i bought a pair of pinhole glasses which I found very uncomfortable becuase I think the holes are too wide so they're always VERY visible when you're looking through them.

Anyway, I was amazed by the clarity of things through them so I had this idea to try the standard accomodation exercise (you know the one where you switch between your close thumb and a far object) while wearing them.

I was extremely surprised by what I felt. I felt that the muscles of my face and especially around the eyes are REALLY working. It is a totally different experience from when it's done without the glasses. The eyes feel as if they're really focusing on the faraway object (such as a letter on an eye chart). My theory is that the eyes are capable of 'locating' the distant object since it appears clearer and therefore are more capable of knowing how to focus.

After doing the exercice for about 2-3 minutes things start to look clearer (subjectively).

Any thoughts on that?

george

That was the first time I had my eyes checked early (8:30AM) and I did not wear my glasses before the exam. I must say that the environment (the optometrist's room) where the eyes are checked is the most unnatural I have seen.

This time he did not do a test from scratch, he started the test from my last test's results. BTW, what are plane lenses?

There's no way back to the darkness of myopia and constant wearing of
glasses

thanks and congratulations on your progress.

Two diopters off in 10 days!?! Alex, do you really believe this estimate?

Using the reciprocal of the far point of clear vision to estimate the myopic error, while theoretically correct, suffers from many practical deficiencies.

First, how clear is clear? If Linda "can focus print up to 26 cm away" I don't think she means she can see it clearly. The purpose of this reading exercise is to hold the text as far as you are still able to read it but with some amount of blur. This should induce the extraocular muscles, over the long run, to exert the proper force on the eyeball. Then, we don't know if the original 17 cm were of the same clearness. Many myopic (in Linda's range) people read from a closer distance than they can see fairly clearly. And even if she controlled for this, her estimate of clearness may have changed.

Second, does Linda use the same amount of illumination when testing her vision? Illumination, as we all know, has a profound impact on the myope's quality of vision.

Third, does she use the same character type to test her vision?

I also use this naked eye approach to get a rough estimate of my vision. Briefly, the way I do it is the following. I make sure the amount of illumination is always the same. Therefore I don't use daylight but artificial light in the evening from a bulb with the same amount of lumens. Then I maintain the same distance from the bulb to the book (an amateur way of maintaining the same amount of lux not having a luxometer). Then the lamp shade has to be the same. The character type and its sharpness have to be the same. I've had a book with me everywhere I go for the last five years and I use it. I assume the print has not faded during this time. And the posture has to be the same. Also, where on the page you look is important. Clearly, the distance to the top of the page is not the same as to the middle or bottom of the page.

Finally, I measure the distance from the page to my eyes, not nose. This, of course, does not affect Linda's improvement, but the absolute values of her myopic error.

I tend to agree with Linda that her improvement is closer to the figure she mentioned (0.75D). As to the reasons for this improvement, as she herself so rightly asked, I may write in another post.

One last note.

Linda wrote:

>> My vision is about -5.5 in both eyes [...]

How can you state this so definitively in a time that supposedly brings great changes to your vision? At least add "before I started doing the exercises" or something of the sort. I can only be so positive when I say "My vision IS 20/20" or "My vision IS improving". Where is Sigmund Freud to lend some light?

I don't know how old Alex is, but I suspect it's less than 40.
I wonder if he'll still be saying that
"There is no reason to think that reading smaller letters should cause
strain or myopia"

when he's in his mid-forties?

I used to be able to read the smallest of small print with no difficulty
in poor light, and yet now have trouble (in mid-forties) with ordinary
newsprint except in good daylight.

Stefan,

Why are you asking Alex questions with respect to my letter? Wouldn't it be more useful to ask me directly? In any case, i understand your skepticism so i will address your concerns.

> First, how clear is clear? If Linda "can focus print up to 26 cm
> away" I don't think she means she can see it clearly. The purpose of

> from a closer distance than they can see fairly clearly. And even
> if she controlled for this, her estimate of clearness may have
> changed.

How clear is clear? Perfectly clear. I can read print even up to 35 - 40 cm's away, but not see it perfectly. For the purpose of my own examinations, what would be the use in being approximate? When i say i can see clearly, i mean that my particular focal problems have all gone away. There is no more double vision or shadow either in the horizontal or the vertical. There is no more fuzziness in those 'problematic' double ll's and double ss's. The print is perfectly clear and not just readable.

> Second, does Linda use the same amount of illumination when testing
> her vision? Illumination, as we all know, has a profound impact on
> the myope's quality of vision.

Yes, i do use exactly the same amount of illumination when testing. I have a spare room that i have set up as 'vision headquarters'. There i

position my chair, eyechart, and reading material in exactly the same fashion consistently. The light that i use is a very bright 450 watt full spectrum metal halide unshaded fixed position lamp that i used to grow my - ummmm - orchids under. Admittedly this is brighter than usual room illumination, but it is the lamp i use consistently.

> Third, does she use the same character type to test her vision?

I used the same book to measure my results at the beginning of the week as i used at the end. I am working through a different book now that has different type face and page colour. There is a reduction of about 1 cm in near vision. I plan to use the original book to plot my progress weekly.

> I also use this naked eye approach to get a rough estimate of my

And for some reason, you assume that i could not have figured this all out for myself! I am miffed. In fact, i hold the end of a cloth tape measure in my mouth (which is roughly in the same place from day to day!) and measure to the middle point in the book. I lose about 1 cm for the actual biting of the cloth, but since that is consistent, i didn't worry about it too much. I didn't expect the Spanish Inquisition. . .

> One last note.

> Linda wrote:

>> My vision is about -5.5 in both eyes [...]

> How can you state this so definitively in a time that supposedly
> brings great changes to your vision? At least add "before I started
> doing the exercises" or something of the sort.

Picky, picky, picky!!! Ok, if you insist. During my last eye exam which took place on June 12/95, my vision was tested at -5.5 and -5.75. Is that close enough? It was close enough for me. When i

say 'about' that does not equal 'definitively'. Since i have been doing normal VT (ie, before Vision Freedom) for about 4 years with very little change since the first few months, and my 20/40 glasses were about as foggy as they have been for a year, i can be prettly sure that my vision had not changed significantly in the past year. But now we will never know.

I am finding it hard to believe it too, but you know Stefan, this Vision Freedom thing just may be working. Or perhaps not. I know that my 20/40 glasses are making me dizzy so i am now wearing an old pair of -3.5's i got from somewhere. Although i wouldn't drive with them, my other glasses are too strong to walk around in. Anyway, i'll keep you posted.

Truthfully,

Linda Lee

Mark's Notes on Vision Improvement

- *Subject:* Mark's Notes on Vision Improvement
 - *From:* Mark Jones <mjones@auscsmp.sps.mot.com>
 - *Date:* Mon, 18 Mar 1996 14:57:21 -0600
-

I formulated these questions some time ago, but I don't believe I've posted them to the list.

I've taken some measurements of my visual acuity using a ruler and various sizes of type. Two months ago, the letters were clear at about 14 cm (I think it was more like 15-16 cm, but my figures are at home, so I'm being conservative).

Since then, I've been sick twice and just returned from a long trip (6 hours of driving Friday and Sunday). Today, I'm measuring clarity at about 13 cm without any VT prep. My question is on the nature of clarity for the sake of measurement.

I find that the level of clarity for me is independent of the size of the type that I am viewing. I can read/interpret larger type at a greater distance than smaller type, but all type has a slight blur until I reach about 13 cm. Is this the common experience of myopia, or does it indicate any special circumstances of which I should be aware?

I forgot my second question, so I'll ramble a bit about some perceptual observations of recent times. I discovered a couple of months ago that when I driving down the road listening to NPR on the radio, my visual focus goes soft as my mental focus is turned inward. When I turn off the radio I return my focus to the sky/clouds/trees/cars/people/etc (with greater emotional satisfaction, I might add.) This observation

came after I had taken a walk whilst absorbed in mental cogitations. When thinking and obsessing my attention was only half on the world, and I tended to stare at any given spot for some extended period of time. When I chose to observe the world, my vision was crystal clear (wearing glasses, that is) and my gaze shifted rapidly to take in the whole view. So the insight for me at that moment was that I was not making the perceptual choice to see and connect with the world as it is.

At some later time I integrated a line of thinking I had considered years before, but forgotten: that there are no objects; we don't even perceive objects. What the world presents to us is a whole connected field of awareness. I can't think of a single incident in which I have perceived an isolated object, unless it was the illusion of an isolated object created by someone else. The result of applying this line of thinking is that now, for the most part, my eyes shift much more frequently and rapidly across the available stimuli in order to more consciously take in everything and the interrelationships of everything. I still fade out when listening intensely or thinking or creating something, but it's a choice, and I am more aware of how to restore my perceptual connection to the world around me.

I would be interested to know whether others have discovered similar issues in their awareness.

Same here. I don't even bother to measure. It's always independent of distance and size, except for that short stretch of space in front of the eyes where it's always clear. Starting from the outer border of that space, everything uniformly follows the clarity or the blur of the moment. Lighting, on the other hand, used to be the only crucial "outer" parameter, but is getting less and less so.

Btw, the `_closest_` point where I can still maintain binocularity yields microscopic vision. Anyone else with this experience?

<snip>

>I would be interested to know whether others have discovered
>similar issues in their awareness.

A whole caboodle. In fact, I now have to restructure my whole philosophy on a nearly daily basis... weekly or monthly as a minimum. Once I seem to adopt a "final" view of the "true nature of..." (whatever, you name it, insert in brackets), this mental attitude translates itself into physical "staring." Any shift towards new ideas, mobility, flexibility of thought, manifests itself in a new visual improvement. I feel I'm doomed to never ever become a proponent of any orthodoxy (or any replacement unorthodoxy that evolves to assume its functions) if I want my vision to continue

improving. I don't know how common this is, but my eyes and my mind do things in strictly identical patterns.

Elena

Read the fine print, Mike. I said "given normal acuity." Acuity depends on first, how sensitive, or "hi-resolution" your retina is, and secondly on how accurately you're focusing on it.

If you have amblyopia, this means the image projected onto your retina -- in focus though it may be -- is reproduced with below-normal accuracy in the brain. Thus, acuity below normal.

If you have presbyopia ("old age" farsightedness) this means that the

images of close objects are not projected onto the retina in focus; the out-of-focus image itself is reproduced "accurately" in the brain, acuity, of course, is below normal.

My point was that the normal eye is capable of reading much smaller print at a comfortable distance than is realized. When letters are too big, readers are allowed to get by with less focusing accuracy.

Bates was probably the first to come out and say "fine print is good for your eyes." R. Brooks Simpkins in "Basic Mechanics of Human Vision" also made a point of this. I myself have experience that confirms this notion.

Often after using graphics software, even when sitting at the monitor at a close range without plus lenses, my distance vision is quite sharp. I noted this first when I was designing a font of special phonetic letters. When I'm doing word processing, I usually see worse afterwards. Therefore, I am inclined to think that close work per se is not necessarily going to make you myopic -- only the kind that dampers your appetite for sharp vision.

Philosophizing further, I now say... heavy readers learn to analyze details with their left brain instead of their right brain. They learn that a "t" is a "t" whether it has a serif or not. They learn to ignore itty bitty details of form and do all their analyzing with their logical mind.

--Alex

>
>I just remember reading something about that but I can't remember where or
>what.

I was pleased to see your post because the relationship between hypnosis and myopia reduction or more accurately, acuity improvement, has been an interest of mine for many years. I began learning hypnosis in 1973 while a graduate student at the University of Houston and the results were so exciting that I even taught medical hypnosis to doctors between 1975 and 1977. I subsequently published a paper on the optometric use of hypnosis.

"Hypnosis - New Horizons for Optometry." Review of Optometry, Vol. 115(10), pp. 53-58, 1978.

Since then I use the principles of relaxation and suggestion with my clients and have recorded these in a series of audio tapes. I chose each eye condition and then designed a hypnosis tape for that condition. Nearsightedness is one of these tapes. The idea is that in a relaxed state the unconscious mind is suggestible to new ideas and the tapes literally program a farsighted perspective. If any of you would like to experience these tapes, request the condition tape you desire and then I can mail them to you. The cost would be \$12.75 U.S. per tape (mailage included) The choices are

Nearsightedness, Farsightedness, Astigmatism, Letting go, Regenerate, Retinal, Corneal and Iris conditions, Macular Degeneration, Glaucoma, Cataracts and Retinal Regeneration (Retinitis Pigmentosa and other degenerative conditions) and Floaters.

All the best on your journey,

I had 20/20 in mid '95, after that and doing much more close work than ever before my vision is about -1.00L and -1.25R

Im thinking of ordering that package, and i would virtually do anything to get my acuity back to 20/20

Does anyone thing that VF would really work on my myopia, or does anyone have any suggestions?

Thank you,
Eugene

Reading in the light of the monkey experiment

- *Subject:* Reading in the light of the monkey experiment
 - *From:* Elena <solusrex@soho.ios.com>
 - *Date:* Wed, 20 Mar 1996 19:23:58 -0500
-

Does it strike anyone as odd that when monkeys were kept in restricted visual environments and developed myopia, it was interpreted as proof of something that reading does to the eyes? How come forcefully restricting an agile young animal's choices and mobility is seen as the equivalent of reading? I'm sure it's beyond the monkeys' understanding too -- I bet they interpret it as animal abuse. (That's not an animal-rights statement by any means, just an understanding of the content of the experiment that seems a lot more straightforward).

>From this perspective, if reading is interpreted by a human child or young adult as something restrictive, immobilizing, superimposed rather than chosen, etc., then it stands a good chance of becoming a myopia-inducing activity. Given the excruciatingly boring standard curriculums, ill-attuned teaching methods, and the whole paradigm of restrictions imposed by impersonal schooling, reading may, and does, become detrimental to the eyes when it's subjectively perceived as a component of this artificially impoverished environment. So I think its effects should not be considered out of context.

That's the problem with "scientific" experiments in general: in any system of any complexity, changing only one parameter without affecting an X number of other (often unknown) parameters is generally impossible. The more the scientists succeed in creating an unbiased, double-blind, pure, Platonian situation for their experiment, the less it will resemble any real-life situation in which the phenomenon being studied occurs. Those of you who have recently commented on the environment of an optometrist's office (and those who didn't but remember their own experiences) must have noticed (not necessarily consciously, maybe as some internally validated "gut feeling") the weird sensations associated with being_examined by someone who is scrutinizing you for

_what's_wrong_with_you (just imagine this approach to you as a real-life situation in ANY context -- as a professional, as a parent, as a lover, as someone dressed in a certain way, etc... and shudder!). You probably can readily compare the way your eyes performed in that situation with the way they behave while taking in some scenery you're finding gorgeous. So what do you think the monkeys were doing in those ultimate anti-monkey surroundings? Reading? Hardly. They were being forcefully subjected to a lifetime in an optometrist's examination chair.

I can top that. I had good vision up until grade 11; I even passed the vision test for my driving license with no problems. Then at the beginning of grade 11, I had trouble seeing the blackboard from the back of the room where I liked to sit, so my mother made me go to the optometrist. He gave me a pair of glasses (the prescription was -1.00, I still have them as a souvenir) that I used only to see the board in school.

Of course, being a teenager I was very vain and I never wore them any

time except for copying things down from the board. This lasted for two years until I finished high school, and my eyesight did not change. After I finished school, I hardly ever wore them.

About a year after I finished high school, I started going with a guy who really liked the way I looked in my glasses, so I started wearing them more. I really could see better wearing them, and I started wearing them all the time when we were together. Before I knew it, I was having more trouble seeing when I took my glasses off (which was happening less and less). I went to the optometrist again (for the second time in my life) and he gave me a new prescription. This was after a year of wearing my glasses semi-regularly. After a month of wearing this new prescription, I was a fulltime glasses wearer (I was about 20 or 21). I've gotten a new prescription just about every year since.

I'm now 25 years old and my prescription is -5.50 D. Considering that I was only a -1.00 from the time I was 17 till I was 19 or 20, that's a change of 4.50 D in just over 5 years. My eyesight started getting worse about a year after high school, at exactly the same time I started wearing my glasses regularly. And I had perfect eyesight at the age of 16. Most people I know need glasses before this age. My sister (who's 2 years older than me) got a pair of glasses when she was in grade six, but never wore them much. She still only uses them when watching TV sometimes. And to think that I used to make fun of her for needing glasses. Guess the joke's on me!

Needless to say, I am blind without my glasses. I blame all of this on that old boyfriend who liked me in glasses -- if it weren't for him I never would have started wearing them as much as I did. He's long gone, but now I'm stuck with coke bottle glasses.

Cindy

Definitely! More close work practice now = better close work ability in the future!

> MY point was that you should be careful about making statements
> which at first sight appear to be general statements of VT
> faith, but on closer examination apply mainly only to
> young myopes.

Mike, it was precisely my point that the reading of overly large print is bad for all eyes, myopic or not. It makes them "lazy" by not requiring them to use their full capacity of acuity -- that is, fine retinal sensitivity.

I further hypothesized that the lack of "taste" for acuity would make one less susceptible to "creeping" errors of refraction -- blurriness due to myopia OR presbyopia caused by an out of shape focusing muscle. With a good taste for a acuity, these focusing errors would be noticed and corrected before the lazy muscle habits become too well established. My line of reasoning is "well tuned retina" -> "well tuned focusing muscles".

I realize there are a mouthful of presuppositions here regarding the origins of refractive error. If you have more nits to pick (you

mentioned something about disagreeing on the definition of presbyopia) I'll take them on one at a time.

Now I just went back to Brooks R. Simpkins's /Basic Mechanics of Ocular Refraction/ and it turns out he had a much more complex reason for why the finer print, the better -- something to do with parallel rays of light from each letter being able to "fit" through the pupil. I admit I don't understand this one well enough to be able to endorse it.

Alex;

I disagree strongly that presbyopia is caused by "an out of shape focusing muscle". It has been shown that the muscle is still strong, perhaps stronger, with advancing age. The cause is held to be more related to the lens and lens capsule becoming more rigid with age due to increasing thickness and decreasing elasticity. Discussion?

Hi,

I've been listening in on I_SEE for amonth or so and decided it was time to introduce myself.

I am a 30 year old myope. At 13 I couldn't read the blackboard at school and got my first glasses. According to Bates I would have been a typical myope. I was shy and introverted, but I hopefully I've changed since then. Unfortunately my vision has only changed for the worse. At my last eye exam in May 94 I was perscribed lenses of -9.50 R and -9.25 L. This was after I had asked for a lower than 20/20 perscription. The comment from the optitian reads "Reduction +1.25 to follow Bates method!". Note the exclamation.

I estimate that with these glasses my vision is close to 'perfect' now. Hopefully at my next exam in May I will be able to get the strength down a little more.

How did I get to here? A few years back I heard mention of VT on the radio and much later bought Harry Benjamin's book "Better sight without glasses". To start with I worked hard at the exercises, but eventually tailed off when the hoped for instant results did not materialise.

I have read various other books from the library including Bates' own book. I have tried to follow the suggestions, but find some of the imagination exercises hard to visualise. Perhaps it's to do with my tendency to the logic rather than creativity.

Most of my working life has been spent in front of computer screens, I'm a programmer. Even this close work would be impossible without glasses or contact lenses.

A couple of years ago I had several sessions with a local Bates teacher, but gave this up for reasons of cost and time. I also felt I was not making any real progress.

Currently I am getting back into a routine of exercises and trying things from

here and the FAQ. I try to spend as much time as possible without my glasses, but this is very limiting as I can make out very little in anything less than bright sunlight at any distance.

I am reluctant to try surgery at least partly because of the cost, but also because I would like to believe there is an alternative.

I am interested in any advice, comments or contacts.

References, please. Or at least a description of the experiments that
purportedly showed this.

The cause is held to be more related to
> the lens and lens capsule becoming more rigid with age due to increasing
> thickness and decreasing elasticity. Discussion?

My original statement was to the effect that exercising vision at the near
point (in particular fine print) should stave off presbyopia (old-age loss
of the ability to see up close). I said "keep the focusing muscle" in
tune, but perhaps "keeping the focusing apparatus" would have been a more
theory-neutral way of saying it. A stronger statement along these
theory-neutral lines would be that practicing reading fine print would
actually "tune up" the focusing apparatus. Bates of course claimed that
presbyopia could be reduced or eliminated by "practicing central fixation"
as he said, on fine print.

LeRoy Kopisch <kope@primenet.com>, a retiree who has worn glasses for 60
years, claims that _bilberry extract_ has almost completely eliminated his
need for glasses while driving or reading -- and to top it off, he has
LENS IMPLANTS (see post of March 16). According to the standard theory of
accommodation, he should have a completely useless muscle of
accommodation.

I hope LeRoy will be able to verify his ability to accommodate. This could
have huge implications for our understanding of both presbyopia and of
course, of accommodation itself.

There are many other accounts of the lensless apparently able to focus for different distances. For an example, see the "optics" section of the I SEE library...

http://silver.ucs.indiana.edu/~aeulenbe/i_see/library.html

Pay particular attention to the articles by Everard Home. His second article is devoted to showing that the lensless eye can accommodate. His third article is devoted to showing that the extraocular muscles are capable of changing the shape of the eye during accommodation. Of note in his third article is his observation that older eyes are less flexible (distensible). Thus, according to this theory, presbyopia would be explained as a hardening of the outer coats of the eye, not (just) the lens. Also, the relevant muscles would be different.

Moderator's note:

Joe's original query on laser refractive surgery appears not to have been forwarded to the list. As moderator I have control over these things; however in this case my failure to "approve" his post was unintentional.

Anyone interested in "PRK" who joined this list within the past few weeks should go to the February 1996 archives...

http://silver.ucs.indiana.edu/~aeulenbe/i_see/maillinglist.html#archives

There was an extended discussion of various refractive surgeries. If none of your questions are answered there, feel free to post here, or write Stefan Stefanov <stefansi@ctrvax.Vanderbilt.Edu>, I SEE's PRK aficionado (see 1st forwarded message)

As phate pointes out (see 2nd message), this list is more oriented towards vision improvement by means other than glasses or surgery. The newsgroup `sci.med.vision` is a good place to find perennial discussion of laser refractive surgeries and news flashes on such. I SEE is the ONLY public "vision" forum on the internet where you can discuss vision therapy without having to defend your right to free speech against hordes of angry knife- laser- and spectacle wielding men.

Alex;

I refer you to page 49 in Primary Care Optometry by Grosvenor, where he states, "...the major cause of presbyopia is the gradual loss in elasticity of the crystalline lens- loss of ciliary muscle power, if it occurs at all, most likely occurs as a result of the increased hardening of the lens." I recognize that this is controversial and one's viewpoint has a lot to do with how one interprets the data. For example, if one is

enamored with the medical model, one may read the discussion of all aspects of the controversy in Adler's Physiology of the Eye, pp. 402-408, where he seems to prefer the deterioration of ciliary muscle function based on rather dubious (IMO) evidence. As usual in science, we must look at all the data and then most people, being biased, will go with their original beliefs anyway. :) He goes on to state, " Several reports have stated that the human ciliary muscle does not weaken or otherwise functionally decline with age, and even that the contractile force of the ciliary muscle reaches its maximum at the very time in life when prsbyopia becomes clinically manifest." (p.404)

He then proceeds to argue with these studies, but, nevertheless, they do exist and he is after all, only one man.

On a more hopeful note, a professor here at Pacific, Bradley Coffey, has been leading a study on using some VT techniques to stave off presbyopia for at least a while. I don't have the exact references now (it is spring break after all!), but if you or anyone else on the list is interested, I can probably dig something up.

Alex,

I just wanted to make sure that you don't mean that PRK is the only thing I stand for in terms of "vision improvement" methods. Please note (as documented in many of my previous posts here on I SEE and also on sci.med.vision) that I am an ardent proponent of the preventive part of VT mainly by means of plus lens therapy, and that I also leave room for a gradual, over the long term, improvement of acuity through the compressive action of the exterior muscles on the eyeball (Mon, 18 Mar 1996 09:06:04 -0500 (EST)). I also incorporate the numerous psychological/mental/behavioral aspects of vision into the paradigm.

PRK is for those who think that their life will not be long enough for them to go from, say -8.00 D to 20/20 utilizing VT techniques alone.

Regards,

Stefan Stefanov

Right now I'm 17, Maybe around mid '95 i had problems very far black boards, In late '95 the problem became so that i cant see the normal blackboard. I'm reluctant to getting glasses, as i thought that wearing glasses is not necessary now, and that i can sit closer to the black board.

I experience clear flashes now and then, and thought the cause was overusing my pc, i stopped for a while, and the problem stayed about the same, (just more clear flashes). My acuity is about 20/80R and 20/100L. When i put on my sister's -1.00D glasses, everything becomes extremely clear and i can see the 20/20 line, even some of 20/15.

I became a bit scared comparing my vision w/o glasses to the ones of my sister's and i started doing some research on VT. I realized that it is possible to perhaps get my vision down to 20/20 again. But i dont know how...

Can the Vision Freedom permanently make my vision 20/20 in each eye? Or maybe the plus lense therapy or something?

Also, many of the books I've read are filled with inspiring visual recoveries, including Lissett's Scholl's "Hypnovision: A new natural way to vision improvement." (that book deals with hypnosis, I'm a bit skeptical of hypnosis).

Does anyone have any suggestions what i should (or shouldn't) do?

Thanks in advance,
Eugene.

I'm wondering since the person couldn't see the board at 13, is it possible that it was a functional myopia at the time?

Thank all who finally responded. I thought that many people on the list might have pondered PRK - laser correction- and decided that is not (yet) for them. You might have more reasons than I have managed to come up with in the short time I was looking in it.

I found that less than 1% has experienced any side effects 1 year after the procedure. For me this of greatest concern. If you have something to say opposing this 'quick fix', please let me and others know. Thank you

Roman

There are quite a few sites with info, I must say
BTW, the stock is Summit Technology, aptly BEAM

Re: Lazy Eyes

- *Subject:* Re: Lazy Eyes
 - *From:* "Linda Lee" <llee@comox.island.net>
 - *Date:* Sat, 23 Mar 1996 21:36:26
-

I know 7 people who have 'lazy' or 'turned in' eyes - 1 woman, 4 men, 1 girl, 1 boy. I realize this is a very small sample, but ALL of them are affected in the left eye. Dr. Kaplan refers to the left eye as the Sally / female / yin eye.

Does anyone know of any research about which eye is most likely to be affected? Is it usually the left eye, or just my friends?

It does seem that our culture in general tends to encourage male / yang energies (competitive, rational, forceful) over female / yin energies (co-operative, inspirational, yeilding). Could it be that this imbalance is showing up in our eyes?

Any thoughts or discussion?

Linda Lee

Steve,

My story is quite similar. I got my first glasses when I was about 13 or 14 and I think it was mainly due to straining trying to see the blackboard (actually it was a greenboard) from the back of the classroom. I don't think my case was affected by any psychological factors. My vision deteriorated over time until it reached a little over -3.25 in both eyes.

Eight years ago I started wearing soft contacts and my vision was more or less stable at that level for two reasons (that's what I think):

1- the contacts that I got were about 0.25 to 0.50 weaker than what they were supposed to be. The optometrist prescribed them that way not because he believed that undercorrection was good but because it was more practical to get one box of lenses of the same prescription instead of worrying about two boxes!!!

2- I believe contacts are much better than glasses. There might be some people who disagree but I think that because the contacts fit around the area that one uses to see, it allows a much more natural seeing behavior. In other words the wearer does not have to turn his/her head to see objects located at the periphery. Peripheral vision is still active.

I also read the book by Harry Benjamin. and did the exercises he suggested and the ones from this mailing list for 1 month. my vision improved from by 0.5 and 0.75 in 4 weeks. It's been like that for the last 5 weeks. I'm still doing the exercises on a daily basis.

I know how you feel about not getting results. Getting results is what drive people to continue doing certain activities. I admire some of the people around this list who have been practicing VT for years!!! I don't know if I will be able to do that but I'm sure that I will not let my vision deteriorate.

Good luck

george

Subject: A suitable case for treatment?

Hi,

I've been listening in on I_SEE for a month or so and decided it was time to introduce myself.

I am a 30 year old myope. At 13 I couldn't read the blackboard at school and got my first glasses. According to Bates I would have been a typical myope. I was shy and introverted, but I hopefully I've changed since then.

Unfortunately

my vision has only changed for the worse. At my last eye exam in May 94 I was perscribed lenses of -9.50 R and -9.25 L. This was after I had asked for a lower than 20/20 perscription. The comment from the optitian reads "Reduction +1.25 to follow Bates method!". Note the exclamation.

I estimate that with these glasses my vision is close to 'perfect' now. Hopefully at my next exam in May I will be able to get the strength down a little more.

How did I get to here? A few years back I heard mention of VT on the radio and much later bought Harry Benjamin's book "Better sight without glasses". To start with I worked hard at the exercises, but eventually tailed off when the hoped for instant results did not materialise.

I have read various other books from the library including Bates' own book. I have tried to follow the suggestions, but find some of the imagination exercises hard to visualise. Perhaps it's to do with my tendency to the logic rather than creativity.

Most of my working life has been spent in front of computer screens, I'm a programmer. Even this close work would be impossible without glasses or contact lenses.

A couple of years ago I had several sessions with a local Bates teacher, but gave this up for reasons of cost and time. I also felt I was not making any real progress.

Currently I am getting back into a routine of exercises and trying things from here and the FAQ. I try to spend as much time as possible without my glasses, but this is very limiting as I can make out very little in anything less than bright sunlight at any distance.

I am reluctant to try surgery at least partly because of the cost, but also because I would like to believe there is an alternative.

I am interested in any advice, comments or contacts.

Exactly, plus lens therapy. You can achieve the same result on your own, without having to pay this miserable snooper (btw he's no longer on the list). Anyone who has read schemes on how to make money quickly will immediately find the ramblings on his web page to be exactly the same in nature: bla-bla without saying anything specific.

Interestingly, though, plus lens therapy is one of the most powerful tools in combating myopia, if not the most powerful. Plus lenses make the eyes "feel" as if you are looking in the distance while you are reading at something 33 cm away. Eyes focusing at near for a prolonged time is the primary cause of myopia.

Go ahead with the plus therapy, but you don't have to shell out \$100 or so into the pockets of that jerk. And beware of anyone who promises you something permanent. Permanency and/or further improvement is only up to you.

Stefan

Maak that another bad left eye here, plus my daughter, plus
my father (so it would seem to be hereditary factors in our
case. FWIW, my daughter and I are both left-handed.

I just realized that the year I got into glasses was also the first year I was in a classroom with no windows to the outside. The furthest we could see was inside the room! Before that I was often scolded for staring out the window, "day-dreaming", but my grades were always good.

I think I'll go move my computer nearer a window :D

I know only one woman with a lazy eye (and yes, it's her left eye), but I've noticed another interesting tendency. Among my friends, there's never been anyone with just "ordinary" eyes. Most are myopic; one woman has perfect-sighted but incredibly huge eyes with outer corners turned downward (like the subway ghost in *Ghost*, the movie); one guy used to be nicknamed Martian because of the inhuman, piercing blue of his eyes; even my mother-in-law has highly uncommon eyes (round, unblinking, and green, like those of a cat mesmerizing a mouse). My acquaintances who are just acquaintances tend to have "normal" eyes. I don't know what to make of it, except if there's a selection mechanism at work it's not conscious.

You are very lucky to be able to do that. I would major that most of us who use Computers for a living don't have the luxury of being able to move our work areas.

I do have a cubicle, so I gaze across the hall into a neighbor's cube. This is a distance of about 20 feet which isn't great. Also, I try to take hourly breaks for about 5-10 minutes (when the boss isn't looking (;)).

I'm currently using a monochrome tube at work and am praying for the day when I'll get color, which should make my life much easier.

I_seers.....I have been fortunate enough to find a vision care professional in town who is open to vision therapy and interested in working with me on my quest to improve my eyesight. Last week I had an appointment with him and had a VERY thorough examination (2 hours). He has documented my improvement from 1993. My right eye w/o contact is now -4.25; was -6.25. My left eye is now -3.75; was -5.0. My previous estimates, based upon reading distances were better than those but admittedly were based upon maximum reading distance rather than absolute clarity. Anyhow, he is willing to fit me with under-prescribed but driving-safe eyeglasses, and considers this a learning experience and somewhat of an adventure. He is open to the idea that this can work, and intends to educate himself on the underlying theories. He seems very interested in hearing how I have acheived my current progress. I have agreed to be re-examined tomorrow to verify the results of the first exam, and then we will work out the prescription. I'm very optimistic about this as my acuity has continued to improve noticably. I am giving up my remaining contact lens in the right eye altogether, and will use the eyeglasses only for driving and when truly necessary at work. I'll continue with the exercises and reading in the "fuzzy zone" which I believe has helped significantly. I'll keep you all informed.

Actually, for a 1.5 D. myope, 20% IS COMPLETELY WITHIN ACCEPTIBLE MEASUREMENT ERROR. It doesn't take a rocket scientist to understand the existence and necessity of refraction tolerances.

No thanks. Been there, done that. Not that I object to its existence or purpose. It's just that friendly encouragement to walk around without your glasses is not going to cure myopia. Never has, never will. The bet still stands.

I'm using the +1.00D lenses to possibly get my myopia from 20/100 to 20/20, I was wondering though would simply using the + lenses for all close work such as pc would be efficient as opposed to doing exercises with them (i.e. moving the text away). Would plainly reading w/o moving the text still help?

A thought.

In the Journal of Behavioral Optometry (Vol 5, 1994) Steve Gallop. O.D writes:

" Why cannot this incredible brain recalibrate a certain amount of blur into clear, meaningful image? A study was done where they recorded from cells in the frontal cortex of the brain while stimulating the retina, and showed that the patterns in which stimuli are received, even on the retina itself, can be reprogrammed from moment to moment, and this ability can be demonstrated physiologically. ... the motor-output system of the brain (efference) has an effect on the input (afference): the brain selects its input. This has been demonstrated on both the psychological and physiological levels." (he refers to a book called: The Psychology of consciousness, by Ornstein RE.)

What's my thought?

O.K. I believe the brain can adjust to eliminate the blur that we myopes suffer from. The keywords in the above quote are 'certain amount of blur' not all the blur at once. In other words, it can do it but it needs some hand holding. When we just take off our glasses and start wandering around with our -3, -4 or -5... eyes it gets pretty tough on our brain no matter how wonderful it is. So why not make it easier for it. Why don't we exercise the eyes wearing a weak prescription so that the eyes try to adjust for a little difference not a big one? Wouldn't that be more logical? Any ideas?

BTW, has anyone read the above Ornstein's book?

From: ws@ix.netcom.com(William Stacy)
>Nope. Nobody would take up the bet. I got tired of waiting for someone
>who had the courage to put their money where there mouth is.

My experience has shown me that it takes more courage to turn one's back on the prevailing tradition and undertake the journey of one's own vision (such as improving eyesight).

Speaking only for myself, money is not a strong enough motivator. I'm into the adventure and the learning possibilities as well as better eyesight. For this reason, in part, I decided not to pursue your offer. The other reason I decided not to pursue your offer is that it doesn't sound very exciting as a financial proposition. I believe the original statement of the offer included a negative motivator. A subsequent statement contained a slight clarification on the rules that seemed dangerously close to a revision. To be frank: your prospectus was not promising (in my personal view).

I continue to pursue vision improvement for my own benefit.

Good luck in your future endeavors. I hope you find great profit and greater courage.

Mark

Come on guys, Bill Stacy ain't all bad... If you're in the northern hemisphere, there's a comet to be seen, according to Dr. Stacy.

Yes, that book uses simple hypnotic suggestions to first induce one into a hypnotic state, and then tell the person "Your vision is getting better everyday... When you look into the distance the ciliary muscle will relax..." The author also incorporated general Bates techniques into it...

Although the thought of hypnosis doesnt really appeal to me... How does one know that one's in a hypnotic state?

Hopes this helps,
Eugene

Yes, that's true, there is a comet out there right now. Two weeks ago I went to the Vanderbilt U Observatory (which is on a hill just outside Nashville) to watch the Orion Nebula. The observatory has a decent 25 inch refractor. An astronomer there told me about the comet but its name (the comet's) escapes my mind now, was a long one.

I was gazing at the sky last night but couldn't see anything but stars and passing planes. May be I do need 20/20s to see that comet. I'll try harder tonight. Happy cometgazing to all I_SEEers! Shall we forget about ciliary muscles and axis flexibility at least one night :-)

My trick was to sit at the computer screen with plus lenses on, and sit as far away as I could, pushing back whenever I could. Letters were never blurry, at most they were on the edge of blurriness. When they got clear, I pushed back just barely. It helps to use the smallest size fonts available; the bigger the font, the less accurate your focusing may be.

When I first got my glasses, I used to take them off to use the computer, just as a habit. I also liked knowing that I could do without my glasses. Then I noticed that I couldn't read the computer without them. So I started using the glasses for the computer. After throwing away my glasses, one of my first vision improvement "victories" was gaining the ability to see the computer screen absolutely clearly from a comfortable sitting position without glasses. I just continued the process using drugstore reading glasses. At first I was afraid of mis-training my convergence (eye-crossing habits) by using two eyes through the plus lenses. I still think an eye patch is a good idea because it lets you train each eye individually (if you do it with both eyes open, it may happen that only your "dominant" eye will improve), it allows one eye to refresh itself, and you use less brain-energy, since you only have to coordinate one eye.

Since you say you are sixteen, I think it will be a matter of months before you become 20/20. Bates said that everyone under sixteen could be cured of any refractive error within a year by practicing distant vision on "small familiar objects" such as letters. Bates's method was to use a distant eye chart and step backwards; lenses simply turn your computer screen into a virtual eyechart. You can practice distant vision and do close work at the same time.

I never really could get used to reading a book with the reading glasses. It was always much easier to sit up straight and look at a computer screen. Reading a book is hard for me to do comfortably in general, and

even more so with glasses of any kind on (I never in my life read books with my minus lenses on). But I found with plus lenses and a patch, I could sit for hours at the computer with absolutely no eye strain, and as a bonus, my vision would noticeably improve afterwards!

It was pretty visible last night.....If you follow the big dipper to the north star (make a straight line from the 2 end stars) you will see a 'blur' very close to the north star. That's it. Now this comet traverses the sky pretty fast so it's relative position will be different today....

We have been watching it here in south Florida since last week (Thursday, I think). My dear husband wears full correction contact lenses, but I was the one to first locate it with my half scripts :D

To really get a good look, I did use binoculars, once I knew where to look. I think the tail was most dramatic Friday and Saturday. To me, it looks like a greenish smudge covering a bright spot.

The sunlight and your freshness after a night's sleep have definitely helped you see better. But you may be interested to know that one of the primary reason's for clearer morning vision is the fact that the cornea thickens 4%-8% during sleep. This effect wears down after the first two-three hours of the day.

>Oh, BTW whats your vision now? (I'm wondering since before you said that

Julie,

Next month I will probably try doing the exercises with my weak prescription and see how it goes. Logically I think it'll work, practically? who knows!!

george

Subject: Re: A thought: Doing exercises with glasses

No I haven't read Ornstein's book. I think cold turkey with the glasses is hard. It may make the improvement go faster but I don't think there is much research to answer the question either way. I go cold turkey outside and often use a lower prescription inside. If I go bare, every little thing I do is so much more of an effort. It's like wearing ankle weights all day long. It's a pain, but maybe worth it to be beautiful.
Julie Ralls, M.D.

Unfortunately, I got lazy and my acuity has slipped back. I see great outdoors, but indoor vision is very variable. I can read the chalkboard from the back row, and often can read street signs that people with 20/20 vision can't. But I'm not consistently blur-free. A lot depends on what I'm looking at, light conditions, state of mind... Remember, I had about six years of glasses, plus at least three years before that of sub-normal vision, before I started. Old habits die hard.

How could Alex, founder of the International Society for the Enhancement of Eyesight let this happen? Why doesn't he go for the gold?

Well, last year at about this time I was reading Bates and trying to prove to myself his theory that one can/should cure myopia WITHOUT GLASSES (even plus-lens glasses). He even went so far as to say that near work was not the cause myopia (I note, however, that his method for myopia prevention was not inconsistent with the idea that near work causes myopia)! There was also an optometrist, Joseph Kennebeck, who wrote a book called "Why Eyeglasses are Harmful for Children and Young People," which I was reading. He said that simply by not wearing glasses and avoiding "too much" close work, one's eyes would tend towards normal as long as they don't wear glasses -- at least for "children and young people" (to be fair, Kennebeck said in his book that he did not prescribe glasses "for wear", leaving the implication that he prescribed plus lenses for training. I have talked to his niece, who confirmed that he had special glasses for training with easily removable and replacable lenses.)

I had also fallen into a sort of pessimism because of the lack of support from people who I thought should be supportive in this area in the scientific community, so I wasn't trying as hard as I should have.

Well, after a year of just trying to "relax and see" I realize I'm going to have to work at it to get that prize of consistently clear 20/20 vision.

I must say that I'm very encouraged by the recent reports of success and determination from George, Linda, and yourself, Eugene. I'm also encouraged by some letters I've been getting from subscribers of misc.health.alternative who read some of my posts, who have read my article on the preventability of myopia...

http://ezinfo.ucs.indiana.edu/~aeulenbe/i_see/prevent_myopia.html

...and who are giving plus lens therapy a try.

Even Brian "Vision Freedom" Severson has been an inspiration, just the fact that he offers a 100% money back guarantee for lens-based therapy. For those who question his "commercialist" goals and over-secretiveness as to what makes his product different, just remember -- his product is primarily information. Would you ask the editor of the Wall Street Journal to send you "free" stock price listings before you buy the newspaper? I don't think so.

Having said that, I still believe it is possible to prevent myopia without plus lenses, and that over-use of plus lenses by people with normal vision may lead to early presbyopia (old age sight).

Also, I believe there are important elements in the Bates method, such as shifting and palming, that can increase the effectiveness of plus lens therapy.

Remember, we're all pioneers here!

First let me note that EVERYBODY'S DIFFERENT. What worked for me may not work for you. Wearing a patch on the wrong eye, especially if you have lazy eye or cross-eye, may make your vision worse. When in doubt, check with your eye doctor.

Anyway, what I did for my "intensive vision training" course that pushed me over from 20/50 to 20/20 was to wear a patch over one eye for the whole day, with the other eye looking out through a plus-one lens. I alternated the patch over the eye each day. This is not for the faint-hearted, and certainly not for people who drive or otherwise rely on clear vision for their safety or the safety of others. Remember also that my previous prescription was -1.25, and that I had already experienced some improvement before this "treatment." After a few days of this I was able to see 20/20 indoors with normal lighting for a couple of seconds. Why haven't I done this again? Why didn't I continue for another week or month until my muscles stabilized? Good questions. As I said on my previous post, I've been trying (not that hard, admittedly; for example, I can't make myself palm for an hour a day as Bates suggests) to improve my vision without relying on the plus lenses. Now I'm convinced that plus lenses are going to be necessary if I ever am to get back to 20/20.

Stay tuned.

Actually it's the Comet Hyakutake. It is probably the brightest comet to appear in the last 20 years. It has an unusually long tail (some say the most impressive this century) and, if you are lucky to be in the right place, you should be able to see the tail stretches across as much as a quarter of the visible sky. Its visual brightness depends largely on the gazer's distance from cities, where man-made lights make it hard to view the night skies.

OK, thats good at least my eyes are capable of seeing 20/50, which consider pretty good considering all of those people with -7 and on sci.med.vision.

Right now i wear a +1 lens for all close work such right now. I was very interested in one study done that i've read on I-See www page. Where a patient was -1 and -1.25 and wore +3.5 and then +4 for all close work, and then his acuity was 20/20 in one eye and a little worse in the other. However +3 lens that i have are extremely strong, everything is very blurry when I put them on. And in order to read i have to be 2-5 inches from the CRT.

In order to see fine (not fully sharp, but readable) with +1 i sit 19-21" away, any comments on this? when i take them off i see the 20/70 line,

and then my vision wears down to 20/100. (i started VT 2 days ago).

Thanks for displaying that the + lenses worked... You sure have given me a boost of confidence, if I ever get my vision to 20/40 or even.... 20/20!! I will never stop. Like today for example i was walking from school (high school), and suddenly everything sharpened so clearly, that i just had to stop... I could see every face on the street, every street sign, store sign, etc... It must have been 20/20.

Eugene

Speaking of outdoors this is the best place for me to get clear 20/20
flashes, also i have noticed that if i blink a certain way, that makes my
eyes moist i can achieve clear vision. My inspiration was hindered that
blinking "that special way" makes the cornea have the smoothest surface
by the tears, which makes me see 20/20... Blinking that way is sure
handy if you want to see something far.

There is something that strikes a chord; as I have mentioned before I think, being a n amblyope in early childhood, I was prescribed heavy plus glasses (as well as patching, etc); I never really understood why (it was never explained to me in ways that I could understand), but it seems to have been a fairly common way of "treating" amblyopes.

I stopped wearing glasses at around age 16 (with sort of tacit consent of my then eye doctors).

Now in my mid-40s I seem to be well and truly presbyopic, but what is interesting, and what strikes the chord with what Alex has said above, is that I can remember having some Presbyopia symptoms aged around 28, i.e. difficulty reading street maps under artificial light at night(*), difficulty reading certain sorts of printed colour combinations (e..g black on red. Most difficulties were by artificial light. None of this really affected my way of life until I got into my 40s, when reading almost anything by artificial light, especially in the evening, became a torture.

Of course, I haven't helped myself by spending most of my working life either looking at a VDU screen of one sort or another, or using microfiche readers. (I'm a systems programmer).

I sometimes get the feeling that my eyes have been "burned out" by staring at these screens all these years. *sigh*.

Mike.Ellwood@rl.ac.uk

(* with what were at the time, chaotic consequences on my honeymoon, but which with the benefit of hindsight now seem hilarious! :-)

Role of iris in accommodation

- *Subject:* Role of iris in accommodation

I hereto copy parts of Richard McCollim's recent s.m.v. post and my reply (leaving out of both a few paragraphs pertaining to some plume-plucking of some s.m.v.'s licensed peacocks).

From: mcollim@ix.netcom.com(Richard McCollim)

Newsgroups: sci.med.vision

Subject: Re: Eye Exercise

Date: 28 Mar 1996 20:54:43 GMT

Why can't eye researchers resolve once and for all some of the most basic questions about eye mechanisms? The answer is probably that they think they have already done so.

To cite just one example of a "settled" question, what is the role of the iris in the mechanism of accommodation?

The iris is one of the most studied of all eye mechanisms (probably because of its relationship to other physiological and psychological questions not directly related to ophthalmology). Apparently the number of papers on this subject runs into the tens of thousands.

It has been accepted that the iris plays no role in accommodation ever since the experiments of the last century, particularly that of von Graefe.

But there still remained a problem. How to explain the fact that when the eye accommodates for near vision, the anterior surface of the eye assumes a conoidal shape?

Fincham came to the rescue by asserting that the lens was molded by differences in thickness of the capsule, and it seems that this was accepted without question, even though these differences are minute.

But there is another way to explain this conoidal shape of the lens: molding by the iris, with the central portion of the lens being forced

through the pupillary opening. There are a surprising number of reports in the literature (I cite only four of these) that support this possibility:

Lowe reported that "During examination of a large series of eyes that had pupils dilated after peripheral iridectomy...I was struck by the marked curvature of the anterior lens surface within the enlarged pupil. The lens frequently appeared as though it were herniating through the enlarged pupil, with the pupillary margin of the iris seeming to grip the lens." (1)

Jampel and Mindel, in a report on stimulation of the oculomotor nucleus in monkeys, observed changes "... characterized by a conspicuous forward bulging of the pupillary or central portion of the iris which produced a marked convexity of the iris diaphragm and a marked increase in the depth of the anterior chamber...On observation of the eye from the side during iris-bulge, the central portion of the lens appeared to become conoidal and to move forward into the anterior chamber." (2)

Burian and Allen reported that "The most remarkable change was seen in the middle one-third of the body of the iris. This part of the iris bowed backward during active accommodation, forming a deep hollow, and returned to its normal position when the eye was relaxed." (3)

And Suzuki states that "Concerning the iris, its silhouette was a slightly curved line, being convex anteriorly in the form of a physiological 'iris bombe'. On stimulation, the iris showed a peculiar change. That is, besides the change of the contraction of the pupil, the iris was bent reversely to the posterior chamber, so that the central half of the iris was held in contact with the anterior surface of the lens and the iris-lens apposition became tighter over a much larger area." (4)

In the rhesus monkey there is a similar mechanism involving the iris and the sphincter muscle, although it is not clear which of these is of greater importance in molding the lens.

It is interesting that all the researchers seemed surprised at their findings. All four of these reports describe the iris as being pressed against the lens, and two of them note that the conoid form of the lens appears to be the result of bulging through the pupil.

The iris/lens mechanism is well documented in certain birds and mammals. According to Walls, "The avian iris is always of material assistance during accommodation in holding back the lens against which it presses, and in inhibiting the peripheral part of the anterior surface of the lens from bulging, thus concentrating the change-of-curvature in the part of the surface opposite the pupil." (5)

Could the iris play a major role in accommodation after all?

The conoidal shape of the lens is important because it relates to the spherical aberration of the eye:

Spherical aberration describes that condition of a lens in which the rays passing through a lens do not all come to a focus /on the retina /at a single point, and this is normal in the human eye. When the eye is at rest, the spherical aberration is positive, which means that the rays passing through the periphery of the lens come to a focus in front of rays passing through the axial region of the lens.

As the lens accommodates to view a near object, the spherical aberration decreases, and at around 3 diopters of accommodation there is no aberration at all, i.e. all the rays come to a focus at the same point. If the eye accommodates further, the aberration begins to become negative, i.e. the peripheral rays come to a focus at a point behind the axial rays. This correlates well with the conoidal shape of the accommodated lens.

In an experiment that I performed on myself, using a mirror/prism device that caused compression of the globe and prolonged accommodation, I produced such a high degree of negative spherical aberration that two separate visual images were formed in each eye.

This indicated that the central rays came to a focus considerably in front of the retina (which produced a highly blurred image), while the peripheral rays came to a focus almost on the retina (which produced a nearly sharp image). Such a high degree of spherical aberration was probably accompanied by a highly conoidal form of the anterior lens, and it is unlikely that the molding power of the very thin capsule could have caused this.

So, what is the answer? It would seem reasonable that after the more than a hundred (?) years of modern ophthalmology, such a basic question should have been answered by now. The investigators mentioned above worked independently of each other and are separated in time by several decades. It is unlikely that they all made the same mistake. But apparently their work has been ignored, and the capsule theory was declared the winner by majority vote long ago. The eye research community 's solution to the appearance of inconvenient facts seems to be just to ignore them.

Too bad about Lowe, Mandel, Jampel et al. All that work for nothing, gathering dust on medical library shelves.

1. Lowe R F. Anterior lens curvature. Comparison between normal eyes

and those with primary angle-closure glaucoma. Br. J. Ophthalmology 8 (Suppl.) 1937.

2. Jampel R S. and Mindel J. The nucleus for accommodation in the midbrain of the macaque. Invest. Ophthalmol. Vis. Sci. 6: 40-50, 1967.

3. Burian H. and Allen L. Mechanical changes during accommodation observed by gonioscopy. Arch Ophthalmol. 54: 66-72, 1955.

4. Suzuki H. Observations on the intraocular changes associated with accommodation: an experimental study using radiographic technique. Exp. Eye Res. 17: 119-128, 1973.

5. Walls G. The Vertebrate Eye and its Adaptive Radiation. New York: Hafner, 1967.

ADDENDUM: So, who cares WHAT role the iris has in accommodation? Is this important? Absolutely. If it is a major factor, then it means that just about every ophthalmologist/optometrist in the world is dead wrong about the mechanism of accommodation. But then how the eye actually works is not a big deal for ophthalmology--what's more important, and gets most of the time, effort and money, are the big money-makers such as RK, PRK, etc.

I got into the iris question in sort of a backhanded way while researching the mechanism of spherical aberration. This came up because I had developed dual vision: I saw two images of everything, one blurred and one clear (superimposed on each other) as a result of compressing the eyeballs--and this was monocular diplopia.

The most logical explanation was a severe distortion of the lens in the form of a lenticonus, i.e. the central part of the crystalline lens had developed a pronounced bulge. The phenomenon described by the four researchers above suggested a possible mechanism: external pressure on the eyeball had pushed the vitreous against the lens, which in turn was pushed forward against the iris, so that only the axial (central) section bulged through the pupil.

This seems to answer a question that's been bugging me since my last eye exam (the first one I had since starting VT nine months ago). The doctor told me that the inner rim(?) of my iris SHOWS UNUSUAL MOBILITY when I focus, moving backward/inward and then returning to its usual position...

and... that was it, I couldn't extract any further explanations although I kept bugging the doctor. "So what does it mean?" I asked over and over. "Well -- it just shows mobility." "And?..." "And it's highly unusual." "Is it good? Bad? Relevant to some issues?" "No, no. Just... unusual."

Now I've been to a dozen eye doctors in three countries in the course of my 25 myopic years and not a single one of them has ever mentioned this, so I assume this behavior of my iris is NEW, AND IS THE DIRECT RESULT OF my successful visual training in the last nine months. I'm sure they would have noticed a lot of other "highly unusual" phenomena in an already VT-improved and still improving myopic eye if they knew where to look.

Elena

Problems

- *Subject:* Problems
 - *From:* G.Raman@cyber-quest.com
 - *Date:* 23 Mar 1996 19:26:58 EDT
-

Hi, I am fairly new to this site. I am a 16 year old myope. My power is R -2.00 L -2.00 . I got glasses when I was 13 years years old because I had trouble seeing the blackboard in school. The summer after I didn't wear my glasses and my vision "miraculously" corrected itself. I tossed away my glassed at that point.

Recently though (past 8 months) my vision has begun to deteriorate rapidly. I got a new pair of glasses and was almost going to start wearing them full time , when I read Dr. Bate's book ,Better eyesight without glasses" . I also found the ISEE web sight. I have been doing the appropriate excercises for about 2 months , but I see no real difference.

DAILY ROUTINE

1. Get up and look out my bedroom window . Read a snellen eye chart that I have hanging in my room with each eye alone, and then with both eyes together. Look at an Astimatic Mirror for about 15-20 seconds, Try to relax my eyes and keep it in focus (I don't know what else to do with it).
2. I then go to school . My eyesight starts out prettty good, but as the day goes on it deteriorates dramatically. By the last period of the school day I almost have to pull out my glasses to read notes that are put up on the overhead projector (I always carry my glasses with me , and I try to resist the urge to put them on but sometimes I have to when I can not read the overhead at all and a teacher calls on me).
3. I then currently go to tennis practice

4. At night I palm for about 7 minutes alternating eyes and then both eyes (sorry , that's all that I have time for , maybe if my teachers would give my less homework!) I then read the snellen eye chart for about 4 minutes in the same manner as in the morning. I then do the long swing about 30 times and go to sleep.

A FEW QUESTIONS

1. What are you really supposed to with an astigmatic mirror anyway? I do have an astigmatism.
2. When doing the long swing, where do you look? Sometimes I look straight out and swing 180 degrees. Sometimes I keep everything in focus and sometimes I don't . Am I supposed to totally ignore all the objects in my room and swing with everything blurry, or keep the room focused? I am really confused here!
3. Do you know any ****specific places**** where I could order some pinhole glasses (and what exactly are they used for).
4. I thought that tennis was supposed to be a good sport for myopes because of the constant shifting necessary to follow the tennis ball. Why do you think that when I come home from tennis practice and palm and then proceed to read the eye chart, it is quite blurry.
5. Do you know of any other exercises that I could do to help remedy my condition. Anything would be greatly appreciated.

Hopefully in the NEAR FUTURE I will return my vision to 20/20 and be able to pass the driving permit eye test without my glasses!

Thank you for all the help!

Ravi Raman :)

Re: Look! A comet!

Since i missed the chance to see that comet before, any chance it will reappear in the near future?

The following message was sent to me a while back by a certain member. It was probably intended for the list.

----- Forwarded message -----
Date: Tue, 19 Mar 1996 20:51:17 -0500
To: Alex Eulenberg <aeulenbe@indiana.edu>
Subject: make it cockeyed

I know that eye exercises are a subject of debate. however I would like to introduce to you a very simple way of improving your sight.

while you are looking at your monitor simply rotate your head to the right or the left and view your screen for awhile. even better if you could have someone to muscle test you while your head is turned. you could find which way needed most of the work.

If this exercise works, I believe it is because it reduces astigmatism. If you imagine an eye with its little pulleys pulling up, down, left right -- this should even out their pull, and round out the cornea. I have also found that looking at things from various angles can sharpen vision.

What do you think?

Plus Lens Therapy

- *Subject:* Plus Lens Therapy
 - *From:* Tim.Patterson@cciw.ca
 - *Date:* Mon, 1 Apr 1996 13:27:26 -0500 (EST)
-

Hi guys. I've been reading posts from this group for ages, but I never say anything. With all the hype about plus lenses, I just about went out to buy a pair. But I still am a bit leery about it. I really do think that you would be speeding your eyes to a presbyoptic state no matter how little you use plus lense therapy. I really support Bate's conclusion that no types of glasses could do you any good. After all, most of us would agree that VT is all about training the eyes on how to see properly, that is, how to look and observe your surroundings. You may be able to change the shape of your eyes in a positive way (temporarily), but unless you use your eyes properly, what good are you doing? I would compare plus lense therapy to laser correction. You can get your eyes shaped to see 20/20, but if you don't know "how to see," your clear vision will almost certainly deteriorate. Note, too, that there are lots of people around with bifocals!

Hello All.

We have heard Alex'es experience with + lenses. It would be interesting if one of the Doctors on the list would describe how/when would they use plus lens therapy for myopia and what would be the schedule of plus lenses usage (Dr Rober Michael.??)

Anyways - cheers to all!

Hmm describe it? its like a rapid (super-sonic) close of the eyelids and  
openness, its usually much less gentle opposed to regular blinking, and  
its done by oppening the eyelids all the way and closing them all the  
way, and its should be done fast... I have trained my eyes to make them  
accumulate just the right amount of moisture to see clearly.
```

To Eugene,

Ref. your question ca. the possibility of the comet "reappearing in the near future"; as astronomy is not really my field, I've referred your query to an expert Astronomer....

Agree. (The "almost", though, needs further qualification. I'll post about it when I get a minute).

In your opinion, "How should I see?" to prevent my vision from deteriorating?

>Stefan Stefanov

I can only say based on what I've read and my own experiences. Basically, your eyes should be looking at different points as fast as possible (without strain). It also has a lot to do with being aware of your surroundings. You really need to "gear your mind" to see, I think. For example, have you ever driven for a couple of miles along a familiar route, and then realized that you can't remember a thing about your last 5 minutes of driving? You weren't in a "seeing" mode, but in a haze or deep thought unrelated to your surroundings. That's when you tend to stare (a no-no according to Bates). I've noticed, too, that people who wear either minus OR plus lenses tend to do this (stare). It's like glasses encourage tunnel vision.

I've also noticed that if I don't expect to be able to recognize somebody down a hall, I usually don't because they're too blurred. If, however, I expect I have a chance of recognizing them, I notice the way they walk, the clothes they're wearing, their height, and I dare say that I recognize their face to some extent (at least I can take a good guess). I have thus "used" my eyes to the best of my ability.

What about the subtle changes in your own neighborhood? Sometimes it has taken me a week or more to notice certain things along my daily route. I

"Seeing"

owe that to not using my eyes properly every day.

I've noticed, too, that people who wear either minus OR plus lenses tend to do this (stare). It's like glasses encourage tunnel vision.

I've also noticed that if I don't expect to be able to recognize somebody down a hall, I usually don't because they're too blurred. If, however, I expect I have a chance of recognizing them, I notice the way they walk, the clothes they're wearing, their height, and I dare say that I recognize their face to some extent (at least I can take a good guess). I have thus "used" my eyes to the best of my ability.

What about the subtle changes in your own neighborhood? Sometimes it has taken me a week or more to notice certain things along my daily route. I

"Seeing"

owe that to not using my eyes properly every day.

Tim

I was searching for information on the net about near-sighted-ness for my daughter who is doing a paper on myopia and I found your page. The possibility that I could see clearly with my extremely defective eyes is exciting.

Plus my three children who are quickly becoming as near-sighted as I - ages 16, 14, 12

I cannot see the E on the chart...

So, I'm afraid I am too blind to hope of ever going without glasses or contacts.

I'm sorry to say I've only gotten through the first half of your 52 pages of instructions - whew...

But I did try relaxation - the vertical eye movement helped with my astigmatism...

I hope this message goes through okay, its really a test for tomorrow, my daughter is to interview people about near-sighted-ness for her "I-research paper" in biology - a topic which affects the student personally.

So, I hope lots of people will respond to her questions!

THANKS

Kath

Thats very interesting, however the original post made by Tim Patterson I have to disagree, just a bit. What I don't understand is the effect of the PRK, RK, certainly they will make the cornea rounder but they will not cure the real problem, ie the accomodation, and the length of the eye ball, shouldnt the problem continue? Laser treatments on the eye, dont really fix the problem (ie the person has to know how to see).

VT, on the other hand *does* fix the problem, at least comes very close to fixing it. I disagree that myopia is caused by "mental tension" (Bates). It's mostly (makes more sense to me) is caused by excessive close work, unless a lyrd is diagnosed w/myopia -- which maybe genetic. But if an individual is diagnosed with myopia at age 13-on (arbitrarily) it must be close work, unless the individual wasnt exposed to close work, to begin with.

How can myopia suddenly start in a 15yr old and be blamed on heredity?

I also dont understand why myopia can be blamed on "physiological

reasons, like mental tension, etc." Evolution is the best answer, as the eyes weren't meant for excessive near point stress.

Thus mostly likely myopia is caused by excessive close work (in my opinion), and VT would certainly be used to get the ciliary muscle to relax.

Kathryn,

>>>So, I'm afraid I am too blind to hope of ever going without glasses or contacts.<<<

Never give up. Read the book "Better Sight Without Glasses or Contact Lenses" by Harry Benjamin and trust me you'll start thinking about the whole thing very differently.

Joining this list is the first step of the way to improving your vision.

I'd be interrested to hear the revelations of your daughter's paper as to what people think about myopia.

Patching

- *Subject:* Patching
 - *From:* "George Tohme" <PolySoft@msn.com>
 - *Date:* Wed, 3 Apr 96 08:17:34 UT
-

On a number on occasion, Alex mentioned that patching is good for the eyes because it relaxes the muscles.

In Harry Benjamin's book which is based on Bates plus dietary stuff, there also some mention of patching but it is in the context of improving the weak eye so that it would catch up with the good one and therefore reduce eyes fatigue.

My question is: which eye should one patch? the bad or the good one? The book says that the good one should be patched to get the weak one to improve by exercising it especially through reading.

Any thoughts?

Subject: Problems

Hi, I am fairly new to this site. I am a 16 year old myope. My power is R -2.00 L -2.00 . I got glasses when I was 13 years years old because I had trouble seeing the blackboard in school. The summer after I didn't wear my glasses and my vision "miraculously" corrected itself. I tossed away my glassed at that point.

Recently though (past 8 months) my vision has begun to deteriorate rapidly. I got a new pair of glasses and was almost going to start wearing them full time , when I read Dr. Bate's book ,Better eyesight without glasses" . I also found the ISEE web sight. I have been doing the appropriate excercises for about 2 months , but I see no real difference.

DAILY ROUTINE

1. Get up and look out my bedroom window . Read a snellen eye chart that I have hanging in my room with each eye alone, and then with both eyes together. Look at an Astimatic Mirror for about 15-20 seconds, Try to relax my eyes and keep it in focus (I don't know what else to do with it).

>>> I tried doing the eyechart exercises with both eyes open and also with only one open. In my opinion both eyes open is better probably because in my case one eye is weaker than the other and it needs something to give it a push. My question is, how far is the eye chart? I look at mine from a point where I can read the top two lines but keep them slightly blurred and work my

way down. As to the astigmatic chart, I think you're supposed to shift your vision along the lines and do the whole circle. I have not noticed any improvement in my astigmatism.

2. I then go to school . My eyesight starts out pretty good, but as the day goes on it deteriorates dramatically. By the last period of the school day I almost have to pull out my glasses to read notes that are put up on the overhead projector (I always carry my glasses with me , and I try to resist the urge to put them on but sometimes I have to when I can not read the overhead at all and a teacher calls on me).

>>> the only thing you can do is to become more conscious about how you are seeing: ie. facial/muscle expressions, staring, straining, blinking rate. It would be help if you could palm for a minute or two (that might cause some interesting comments from your classmates!!)

3. I then currently go to tennis practice

>>> is this too late in the afternoon? Is there enough natural light? Tennis is excellent. I play only at midday when the sun is shining and I use clean balls for better vision. It's great. BTW my eyes are currently at -2.50, -3.00.

4. At night I palm for about 7 minutes alternating eyes and then both eyes (sorry , that's all that I have time for , maybe if my teachers would give my less homework!) I then read the snellen eye chart for about 4 minutes in the same manner as in the morning. I then do the long swing about 30 times and go to sleep.

>>> Good stuff. I don't bother with the swing. I do a variation of the swinging ball: get a tennis ball, put a hook in it, try a string to it and hang it down from the ceiling. Sit on a chair and make sure that the ball is hanging at the same level as your eyes about 0.50m away. Now try these and always follow the ball with your eyes (relaxed and blinking):

- 1- swing the ball from left to right (1 min)
- 2- swing the ball front to back (1 min)
- 3- swing the ball diagonally on each side of your head (2 x 1min)
- 4- swing the ball in a wide full circle clockwise and counter clockwise (2x 1min)

While doing the above notice how objects in the room travel the opposite direction.

A FEW QUESTIONS

1. What are you really supposed to do with an astigmatic mirror anyway? I do have an astigmatism.

2. When doing the long swing, where do you look? Sometimes I look straight out and swing 180 degrees. Sometimes I keep everything in focus and sometimes I don't . Am I supposed to totally ignore all the objects in my room and swing with everything blurry, or keep the room focused? I am really confused here!

3. Do you know any *****specific places***** where I could order some pinhole glasses (and what exactly are they used for).

>>> try the health food shops or the drug stores. The ones I got were very uncomfortable so I returned them and still looking for another pair. People laugh when I ask for them: they either don't know what I'm talking about or they tell me that VT is a garbage!!!

4. I thought that tennis was supposed to be a good sport for myopes because of the constant shifting necessary to follow the tennis ball. Why do you think that when I come home from tennis practice and palm and then procede to read the eye chart, it is quite blurry.

5. Do you know of any other excercises that I could do to help remedy my condition. Anything would be greatly apppreciated.

Hopefully in the NEAR FUTURE I will return my vision to 20/20 and be able to pass the driving permit eye test without my glasses!

Thank you for all the help!

Ravi Raman :)

I don't have a problem with that actually; an individual may be genetically predisposed to myopia, but whether he/she actually becomes myopic may depend upon a number of factors, including close work, diet, lifestyle and general environment.

> I also dont understand why myopia can be blamed on "physiological
> reasons, like mental tension, etc." Evolution is the best answer, as the
> eyes weren't meant for excessive near point stress.

Well maybe, maybe not. How did we evolve our fingers? These are capable of extremely delicate operations, and which perform even better when co-ordinated with the eye. I don't think we evolved only to throw spears at buffalo on the run.

> Thus mostly likely myopia is caused by excessive close work (in my
> opinion), and VT would certainly be used to get the ciliary muscle to relax.
>

As I suggest above, close work is no doubt one factor, but probably not
the only one by a long chalk.

Hi, Ravi

I'm around -1.25L and -1.50R myopia, never went to the optometrist,

and dont have any glasses. Currently 17, (turned last month) my vision began to deteriorate around '95. I see that we have alot of things in common, I'm also trying to get my vision down to 20/20 (using the plus lense therapy), and I do play tennis (pretty good :)).

Well, tell me if your improvement continues.

PS: How did your eyes miraculously corrected itself?

Were you involved in some kind of activities? Did you lessen your close work, and maximize the time you spend outside?

Thanx,
Eugene

That got me thinking, since my father is myopic, and my mother has incredible 20/13 vision, I hope I didnt get myopia genetically. If I did, it would be impossible to reverse it, as the eyes are pregrommed to be longer than usual...

Yes in fact is like having a natural contact lens.

Functional Or Structural?

- *Subject:* Functional Or Structural?
 - *From:* Eugene <phate@lubricant.free.org>

While reading Alex's essay on Preventing Myopia I concluded one thing. Functional myopia (ie ciliary cramp) is curable, while Structural is not. That really got me worried, since I dont know what myopia I have, and I sure dont wont someone paralyzing my ciliary muscle. My diopter is around -1.25L -1.5R, people say its too low to be structural. And when I do PLT (Plus Lens Therapy) I'm able to move the book farther and farther away and still mantain the same clarity...

Is it possible that my myopia can be structural? Anyone know of few ways of finding this out?

Thanx,
Eugene

The Myope's dilemma

- *Subject:* The Myope's dilemma
 - *From:* stefansi@ctrvax.Vanderbilt.Edu (Stefan Stefanov)
 - *Date:* Wed, 03 Apr 1996 18:34:16 -0600
-

I was happy to see some real quality posts recently. I will try now to combine two issues which have hitherto appeared separated.

I do think the primary cause of myopia is prolonged near work. Naturally, the eye adapts by elongating so as to reduce the stress on the ciliary muscles. The lifestyle led by a person who has become myopic is simply incompatible with clear distant vision. This simple, yet profound point has been made before on the list, most notably by Vic several months ago. Therefore, to at least stop myopia from progressing one should not subject one's eyes to prolonged near stress. This is achievable in a most powerful way by plus lenses. Whether plus lenses alone can act to **reduce** myopia is another question. I am still unsure about this and patiently experimenting. I would appreciate other's input. Currently I tend to favor the hypothesis that plus lenses **can** help reduce structural myopia, most probably to a limited degree, but only when the blur resulting from them in relation to the visual target is small enough so as the brain makes attempts to clear the blur (through compressive action on the eyeball by the recti extraocular muscles). If one goes around, say, -4.0 D uncorrected, the brain gives up trying to clear the view as a hopeless task and only prevention is achieved (theories and tests on "myopia from deprivation" add a complicating twist but usually "deprivation" is irrelevant as everyone is almost constantly looking around when not sleeping).

Now, the other issue. The otherwise infamous Dr. David Granet from sci.med.vision made a very good remark to an Alex's post in October '95. He said, a loose quote, "if people become more myopic by wearing full correction then normally sighted people should become myopic simply by using their eyes". To this Alex replied something like "Simple. People vary...". Well, I agree that it is simple in that people vary in their responses to stress. But it is this variance and it's myopic response part that may cause so much pain to some (one may take cold comfort in the idea that myopic people are better at

adapting).

I am sure everybody knows people who work intensively at near and yet enjoy perfect distant vision. Just two of the many such cases I have observed: a) my brother has done near work in comparable amounts to me over the last ten years and often in worse conditions (low light, various recumbent poses, 18+ hours a day computing, add smoking and generally less healthy lifestyle - and yet he has always enjoyed 20/15 vision; b) a close friend of mine and I started working with computers back in 1983 for prolonged hours, he is an excellent programmer, with many international awards, and now runs a software company - he has perfect 20/20 vision - I ran up myopia and quit programming.

I would estimate that the percent of people with vision resilient to prolonged near stress is about 30-40% (this is the qualification to Tim's "will *almost* certainly deteriorate"). The remaining unlucky majority are "susceptible to myopia", i.e. prolonged near work will lead to reduction in distant acuity. One may reclaim lost ground through VT but as soon as one slackens the VT regime, vision slips back (cf Alex's "laziness", Antonia Orfield's slippage). This leads me to one uninspiring conclusion: once a myope, always a myope. And possibly an alternative way out: somehow a myope has to transform himself to the resilient variety. How? I don't know for sure, not even if it is at all possible. Will? Brain reprogramming? I am open to new ideas. One possible negative parallel: no matter how much I eat I cannot gain a pound; many people are quick to put on weight by only a small increase in their calories intake.

So what's the myope's dilemma? As said above, for those susceptible to myopia, wanting to see clearly in the distance while their lifestyle demands prolonged near work. I personally feel very uncomfortable when I settle down for a long reading task and wear 20/20 correction. I once decided I was a slave to this concept and decided to fight it. I failed miserably. Therefore I think plus lense therapy is a very viable technique, at least for me. Not that I love it and don't want to get rid of it. If anyone can tell me how I can walk around all day long with 20/20 vision (lenses or PRK corrected) and keep my vision like this given my 16 hours a day of near work, I'll be forever grateful.

Stefan: I do agree with you on some points but disagree on others. First i thought myopia was some sort of an irreversible defect, then as time went by (much more research and close work later) I realized it's a defect much like any defect in any part of the human body. A defect than can be corrected. That's why it's not myope's dilemma, and "Alex's lazyness," is not a very good reason to say "once a myope, always a myope." Alex just didn't perhaps another month for his

muscle to stabilize.

For example: you run 5 miles w/o stretching, you strain, etc. Same probable thing holds for the eyes -- Near point focusing, as far as genetics is concerned I dont really know about "your eyes being preprogrammed to have longer axial length." Perhaps, perhaps not.

I strongly believe that the human body is designed to fix any defects, but we have to let it to do so (as long as the defect is not genetic). Currently I use +1 lenses for all of my close work, It seems to be working as my myopia now is 20/70L, 20/80R.

Why some people become myopic and others not (ie if they both do equal close work, I have no idea.) All I know that for the past 3 yrs, (when I bought my PC), everyday I come home from school, and turn it on, and play with it for 5-10hrs straight. *Everyday*. I used to have 20/15, but it went down.

So I dont really agree with "once a myope, always a myope," unless its not genetically.

As a certified 1-diopter myope who has experimented extensively with plus lenses, I disagree with the popular hypothesis about the effects of "megaplug" and over-blurring. In fact, what I have found is that wearing +3.00 or higher (sometimes by putting one pair on top of another) a very satisfactory lessening of my functional myopia can be achieved. Twigs on the trees momentarily sharpen up, for example, and double images present before my wearing of the plus lenses are reduced.

People ask "but can this temporary improvement be made permanent"? I think it must be so that anything you can achieve with plus lenses, you can eventually become able to achieve without them. Just remember, that unlike Ortho-K, where it's a contact lens re-shaping your cornea, the only force making your eyes' distance vision better is coming from you. You are making your eye muscles work (or relax, or both, depending on which theory of accommodation you subscribe to) to change the shape of the parts of your eye.

But back to Stefan's point, I question the validity of the statement that only a "slight" blur is capable of triggering an anti-myopia response. The fact is, when something is very blurry, it still becomes clearer if you focus "towards" it. Maximal distance focusing is even more important the more plus-lens-induced blur you're faced with. With 20/40 vision, you can

afford to be imprecise in your focusing. With the 20/2000 vision (or whatever) that mega-plus lenses impose on you, you need every ounce of distance-focusing power that you can muster. I do agree with Stefan that there is a point at which your brain may "give up," but you can't know beforehand what that point is. Furthermore, I have found that with practice, the amount of blur one can clear up can be increased. The key is not to react to the blur by straining. That it is common or "natural" to have a "myopic response" to any sort of blur (as some models of myopia development would have it) does not mean that it is an unavoidable response. You must be comfortable with your visual handicap, and maintain a positive attitude, in order for you to get your body to overcome it.

However, be prudent in your optimism! I most certainly do NOT recommend wearing super-high plus lenses in any situation where good vision is necessary for you. In addition to making things blurrier for myopes, plus lenses make objects larger and appear closer. This can really throw you off balance because you have to focus as if they objects were FARTHER than they appear. So for example, operating a vehicle, walking down stairs, crossing the street -- all these are all dangerous for a myope with plus lenses on. Use your good judgement. Even in the kitchen, there may be sharp knives that you don't notice because the blur has apparently dulled them.

However, for mild myopes I see nothing wrong with sitting in a chair, say, or on a park bench, looking out at the blurry objects and "forgetting" that you're wearing plus lenses artificially increasing your myopia. Your mind "knows" that you're not really that myopic, and if you let it, your subconscious will get your eyes to focus. The improvement in vision after taking the glasses off, having worn them for just a few seconds, can be breathtaking. Now I only speak from my personal experience and a few experiments with acquaintances. I know it takes a lot of getting used to, for a myope to wear plus lenses to see distant objects.

Yesterday during lunch, I accosted a few college students and asked them about their vision. It seems half of the students on campus who do not wear glasses admit to not seeing clearly in the distance. Keep this in mind whenever you judge the percent of myopes by number of glasses (or even contact lens) wearers. They're everywhere! Anyway, I had two of them practice with my plus lens collection for about a minute, either using the plus lenses on fine print, pushing back, or just looking around. They both noticed that they were better able to see the twigs on the trees after using them, but this improvement faded after a few seconds. You may be surprised to hear this, but they didn't really make much of this experiment, and were not terribly excited at the prospect of developing super-acute distance vision.

As for me, when I first tried plus lenses, I got a weird "pulling" sensation around my eyes that was strangely relaxing at the same time.

This could be avoided by wearing a patch over one eye. I no longer get that sensation when I wear plus lenses, although I do seem to experience less strain when using them if I use a patch over one eye. I do not know exactly what the meaning of this "pulling sensation" is, or why I no longer feel it. I assume it has something to do with convergence (turning the eyes inward) being a conditioned response to accommodation (focusing) -- both plus and minus lenses change the accommodation/convergence ratio. If the extraocular muscles are a part of accommodation, there may be another explanation. So be aware, myopes, strange things may happen as you use your plus lenses. When in doubt, consult an eye care professional first.

I remind people that plus lenses for the treatment of myopia is very largely uncharted territory, at least as far as the public record goes (Brian Severson at Vision Freedom may know more, but you've got to pay your \$100 to find out what his secrets are). USE THEM AT YOUR OWN RISK. Now I remember why I have been so reluctant to speak so glowingly of plus lenses, despite my experience. In advocating plus lenses, I come dangerously close to "prescribing glasses without a license." So please do not take my -- or anyone else's -- words on plus lenses as any kind of "prescription." I am simply telling you what happened to me, what I have read, and what other people have told me. Determining what you should do with your eyes is a decision that's between you and your eye doctor.

While I'm on this "see your doctor" roll, I'd like to say, especially to Eugene who says he's never seen an optometrist, please do get an eye examination before you go too far in your therapy. Many people have accused me of discouraging people from seeing their eye doctor. They say that people could possibly have some dangerous condition go undiagnosed and untreated. This scare tactic does not impress me, and I won't use it on you. However, I think you should see an eye doctor anyway. Why? That way, you'll have some "official" measure of your state of vision before treatment.

Then after you've improved, go back for another measurement.

George, with his monthly visits, has been excellent example in this regard.

For the myopic teens on this group, your parents will probably pay for the visit, right? For others, it may turn out that a yearly eye examination is covered by your health insurance, or part of your employer's health care package (here at I.U. all staff qualifies for a free yearly eye examination).

If you want to find a licensed optometrist who is sympathetic to the idea of better eyesight without glasses, check...

http://ezinfo.ucs.indiana.edu/~aeulenbe/i_see/orgs.html

...for names of organizations that can give you a referral.

^^^^^^^^^^^^^^^^^^

One must not forget that other conditions of the body (tumors and all sorts of stuff - any doctors in the group care to expand?) can be detected early on the eye capilaries, thus allowing an early intervention. Regardless of what one may think of Opto's in their ability to cure myopia, presbyopia et al, it's good to visit them regularly.....

Cheers.

For each of the following topics, please give your sources, (personal knowledge, friend's opinion, text, fiction work...) She hasn't read all the FAQ, but there is no need to duplicate anything on the I_SEE web site, she has a copy!

1. Why do objects become lear when they are close to the myopic eye?
2. What advantages are there of eyeglasses instead of contact lenses and vice versa?
3. What advantages over other types of lenses is each of the following: hard, gas permeable, soft daily wear, and soft extended wear?
4. How does laser surgery work?
How is it different from radial keratotomy?
5. What side effects are there to surgery? (longterm?)
6. How does corneal (CK) molding work?
Any information on this subject would be much appreciated.
7. Can myopia be prevented, stopped, or slowed down by natural ways?
8. How is myopia passed on?
(I have a pretty good understanding of genetics, so feel free to use somewhat complex terms. Mrs. Sapiro, my biology teacher recently received national attention for her genetics teaching.)
9. How did you gain your knowledge on this topic?
Are your an expert?
If so where did you receive your training, schooling... please detail how /

where you gained each. Personal testimony is welcomed, but please detail your time and energy in the project of eye improvement

THANKS for your help in answering any or all of the above questions!

Could you answer Questions for I-Search high school research

- *Subject:* Could you answer Questions for I-Search high school research
 - *From:* Kathryn Baker <kbaker@lanl.gov>
 - *Date:* Fri, 05 Apr 1996 08:12:10 -0700
-

For each of the following topics, please give your sources, (personal knowledge, friend's opinion, text, fiction work...) She hasn't read all the FAQ, but there is no need to duplicate anything on the I_SEE web site, she has a copy!

1. Why do objects become lear when they are close to the myopic eye?
2. What advantages are there of eyeglasses instead of contact lenses and vice versa?
3. What advantages over other types of lenses is each of the following: hard, gas permeable, soft daily wear, and soft extended wear?
4. How does laser surgery work?
How is it different from radial keratotomy?
5. What side effects are there to surgery? (longterm?)
6. How does corneal (CK) molding work?
Any information on this subject would be much appreciated.
7. Can myopia be prevented, stopped, or slowed down by natural ways?
8. How is myopia passed on?
(I have a pretty good understanding of genetics, so feel free to use somewhat complex terms. Mrs. Sapiro, my biology teacher recently received national attention for her genetics teaching.)
9. How did you gain your knowledge on this topic?
Are your an expert?
If so where did you receive your training, schooling... please detail how /

where you gained each. Personal testimony is welcomed, but please detail your time and energy in the project of eye improvement

THANKS for your help in answering any or all of the above questions!

--- Beth Baker

VISION FREEDOM - Update

- *Subject:* VISION FREEDOM - Update
 - *From:* "Linda Lee" <llee@comox.island.net>
 - *Date:* Fri, 5 Apr 1996 19:15:43
-

A few weeks ago i got my VF kit from Brian Sevrenson and began his program. I have sent reports to this group in the past so i won't go into much detail. I did have some progress - about .75 diopter improvement by my estimates. Although i am sure his program works well for some people, i have effectively stopped. If you have about 15 minutes and an open mind, i would be happy to tell you why.

The VF program consists of reading print that is just barely beyond your eyes natural ability to focus for 2 hours daily. The object is to consistently move the book beyond your visual limit forcing your eyes to gradually accomodate more and more. The plus glasses are worn progressively if or when your present vision exceeds your arm's length. I tried this for a few weeks. At first, the progress was very impressive but it slowed down a bit in week two. This is not why i stopped. I stopped because of the material i was reading.

The reading is slow going, so i did not want to read a suspenseful book, nor did i want to read a book that was boring, since i would be there for 2 hours each day. It seemed an ideal opportunity for me to return to the spiritual books i have been neglecting lately. I live by the premise that i am a spirtual being having a physical experience. I haven't always been this way. This is where my own journey to overcome myopia has led me and i make no excuses.

I very quickly learned that i have fallen into the common trap of confusing 'Form' with 'Function'. Function refers to the purpose or reason for a situation while Form is the particular shape the discomfort adopts. A person may be convinced that she is worthless and attempt to disappear. The function in this hypothetical case is to prove she is worth less, and the form she may take to express

this could be anorexia. Another person may feel she must hide some guilty secret. She might try to hide behind glasses. The eyes, we are told are the mirror of the soul. If i can prevent you from seeing into my soul, surely my secrets are safe. Until i remove the original purpose for myopia, Vision Freedom training will have no true value to me anymore then a week-end seminar in nutrition will cure the anorexic ... IMHO.

The upshoot however, of function & form confusion is that, although i can 'correct / adjust' the form in which my problem has manifested, if i don't remove the original purpose of myopia it will simply manifest itself elsewhere. If i were to 'cure' my vision without understanding the reason i choose myopia to hide behind, then i would merely hide behind something, or someone else. I might end up with perfect vision and an eating disorder, hardly a useful exchange. I might become an arrogant spokesperson with the misguided beleif that i can now cure the world of anything for a fee.

There are people who have 'overcome' their addictions to alcohol by smoking pot instead, or throwing themselves into their work, or becoming addicted to a religious or self-help group. Many people will go to great lengths to extracate themselves from abusive, even dangerous relationships only to repeat their actions in another situation. Addictions have a purpose, there is a lesson to be learned and IMHO the lessons of myopia have nothing to do with eye shape, genetics or diet. Obsessions with these and other 'hard scientific' factors will simply take my time away from investigating the real cause, or function of my near-sightedness, again, and i stress this - IMHO.

And I do know how to see. I could see perfectly up until a certain age, somewhere between 9 and 13. And there was one day when i had a flash of perfect vision, before i had heard of VT, about 5 years ago. It lasted about 15 seconds, until i had the tiny, mad thought that i don't deserve this kind of joy. I have read that in order to get repeat flashes, i should repeat the circumstances that occurred the last time. That's interesting but how do i repeat an obvious lapse of guilt? This question has led my down many odd turnings but the obvious answer is - Get Rid of the Guilt!

So what is this dark, guilty secret that my glasses have been hiding for so many years? In honour of those of you who are still with me, i will tell you. Perhaps my secret is a common one. I believe that it is.

When i was little, up to about 9 or so, i had the undeniable urge to be good. I wanted to be kind, to be generous, to be loving. I would take myself to church every Sunday, sing in the choir and promise my best friend Jesus, that this week i would make it. I would be good. I wouldn't be rude to my parents, or yell at my brothers. I would do my homework, and clean up my room and be gentle no matter what happened. I would leave the church feeling cleansed, reborn, renewed. Holy! Holy! Holy!

Unfortunately, i couldn't even keep my promise until Monday. My family was noisy. Often, i could hear them shouting a block away from the house. No sooner would i be in the door then my brothers would be pushing me around, yelling, tormenting. Father raging, plates flying overhead, my toys and dollies demolished. Mother's bruised face, no home for a tiny saint. Hail Mary full of Grace . . .

And i don't have to remind you about school, we were all there. Don't colour over the lines. Don't have an original idea. Don't be different even if you are, and we all are. And watch out for bullies -remember the boy with the bloody face?

One day i gave up being good and i stopped being different. I didn't go the church anymore. I didn't suppose anyone would care. I couldn't even keep a simple promise to a guy that was supposedly crucified on my behalf. (I later found out that story was distorted). Surely i was no great loss to the Kingdom of Heaven. I would just hide whatever kindness remained and forget it was there. Maybe God would forget that i was here and i would never have to answer for my broken promises. This is my guilty secret.

But hey, it's not my fault right? Any College trained psychologist will tell my that all i have to do is name the guilty parties, describe in brutal detail all their sins against me, express my unexpressed emotions and i will be free of the shame that binds me. Well, i did that and it doesn't work or at least it doesn't go far enough. I appreciate that i have a very different idea of what healing is. I don't consider myself cured just because i can hold down a stressful job if i have to numb myself out with TV every night.

The argument although well intentioned is flawed. Forgiveness is not saying, hey, i know what you did ... you were terrible ... but since i am a more loving person than you obviously were, i choose to overlook your mistakes. How can i forgive you when i still believe that i am right and you are wrong, i am good and you are bad.

Forgiveness is more complicated and simple than that. I am exploring that idea but not much has been written on it besides the bible and something called A Course in Miracles.

I realize that i have not put forward a very convincing argument, that is, forgiveness versus science. But it isn't my intention to convince anyone and i probably won't respond if you ask me to defend myself. I don't bother with that much anymore. If i have not made myself clear, i will be happy to speak more fully in any area.

My intention is to open up the discussion beyond the physical into areas that have relevance to me. I believe that there is free will in the universe and that i chose to inflict myself with myopia. I have erred in the belief that God is mad at me for not trying hard enough and i want to learn how to forgive myself. Consciously, i realize that i have not sinned nor been sinned against, and yet i still hide behind my glasses. When i decided that i would not be the loving creature i was created to be, i denied who i am. But i left a trail of bread crumbs leading right to my eyes. When i forgive myself, i believe that my myopia will evaporate.

When i started with the Vision Freedom program i was of the opinion that i had learned everything there was to know from myopia. I felt sure that all i had to do now was to tidy up a few loose ends, correct a few bad habits, and zing, my glasses would disappear. I was mistaken. When i no longer need glasses to lead me back to myself, they will disappear. I don't want them to go any sooner than that.

As usual, i'll keep you posted.

Thank you for reading my letter. This does seem to be a suitable topic for Easter, don't you think?

Actually I dont really know if there's need to go as far as saying that myopia is caused by "wanting to see the world in a blurry way", etc.

Its simply a cramp in the ciliary muscle (functional) from close work.
Or the eye adapts to excessive close work, and becomes longer (structural).

I dont how subconscisly you would want to view the world in a blurry way...

Eugene

There has been a lot said about patching in this news group, however, I am still unclear about a few things.

1. Should I be patching my dominant eye or my eye with the strongest vision, or both on alternating days? My dominant eye and my eye with the better vision are not the same.
2. Is there a limit to the amount of time one should spend patching any one eye or an amount of time that one should patch to have benefits?
3. How long should one continue patching? Every day until they see results? Longer?
4. Are there any reasons that one should not consider patching?
5. Does patching have to be used in conjunction with other eye exercises to be beneficial?

Thanks for your help.

Nearsightedness measured in the eye is a reactive reflection of a blurry state of mind. Myopia doesn't begin in the eye. The eye records the outcome of a myopic personality thinking that is both genetic and carried down through the family tree and life experience imprinting. If you try and fix your eyes, then you might as well change your car tires not realizing that the carburetor needs replacement.

I have been a little quiet lately, travelling and teaching. Am home for a few days and then again off to New England, North Carolina and Toronto. Plus lens therapy is ideally used in all case of nearsightedness, where the person is able to successfully relax behind the lens. The amount of reduction is important. I use between +1.00 and +2.00 and find this reduction does not adversely affect the binocular vision status. Anything more than this can cause foveal suppression of vision through one eye. For all close work, look through less minus to get the plus effect. I doubt if you slip on +1.75 without any other lenses, as in the case of nearsightedness, that this will produce major therapeutic advantages. Observe if you are straining and breathe, blink and shift your eyes while wearing the plus.

The value of the plus comes from stimulation of the parasympathetic branch of the autonomic nervous system. Visualize your pupil becoming smaller and your iris muscles more responsive to light. Stay away from sugary items so that the ciliary muscle can be balanced, since it is influenced by the glucose tolerance level. Eat complex carbohydrates. And above all imagine you are looking far away through the plus lens. Enjoy. I'll be back on line by May 6th, 1996

Patch the dominant eye or the eye you see most out of. In your case you can
alternate. Attempt to get as much of a four hour stretch in at one go

>

>2. Is there a limit to the amount of time one should spend patching any
>one eye or an amount of time that one should patch to have benefits?

The benefits of patching, as are all exercises, is the consciousness you
bring to the practice. Patch as long as you are changing your perceptions
and consciousness. To keep the patch on because you think it is going to
help you is probably a waste of time.

Patching can be used to practice one eye at a time when doing exercises in central fixation (shifting, swinging, etc.) If your eyes have vastly different refractions, wearing the patch is very convenient. Otherwise, your "bad" eye (for the particular vision task) will let your "good" eye do all the work. The exception to this is, of course, when you are practicing binocular exercises, such as looking down a yardstick and watching the "V" turn into an "X" and so forth.

ON THE OTHER HAND,

Patching an eye, inasmuch as it lets the eye rest, seems to have a beneficial effect on the eye under the patch, like palming. The rest applies to both the retina (things look brighter afterwards) and to the extraocular muscles (the eye seems to turn about more freely -- as if it's been lubricated).

So should you patch your "bad" eye or your "good" eye? I don't think there are any hard and fast rules. Patching, like so many things in vision therapy, has not been rigorously studied.

I can say as a mild myope with no amblyopia, that patching usually "freshens" the eye that has been patched -- patching benefits my patched eye.

I can also say that practicing shifting is easier with one eye. My eye movements seems easier to control -- patching benefits my unpatched eye because it is "learning" under good conditions. It is not practice that makes perfect, but perfect practice.

> 2. Is there a limit to the amount of time one should spend patching any
> one eye or an amount of time that one should patch to have benefits?

Robert-Michael Kaplan <Beyond_20/20@Sunshine.net> in his book /Seeing Without Glasses/ says that four hours a day is "optimal" (his latest post on this subject confirms this). However, I have gone for an entire day with a patch on. I can't say whether this was better than when I did it for four hours only. I also understand that "too much" patching can lead to double vision or image-repression. Usually when I take a patch off after having worn it for more than an hour I get double images from my eyes not pointing at the same object. This lasts less than a minute -- for me. One article I read said that up to five hours a day is "safe" for amblyopes. But don't take my word on that one. Ask your doctor if you're unsure, or "patch at your own risk."

> 3. How long should one continue patching? Every day until they see
> results? Longer?

For me the results were instant though temporary. But I say, there are no hard and fast rules here. Also, wearing a patch, especially over your non-dominant eye, can be very tiring.

> 4. Are there any reasons that one should not consider patching?

As I said, if you have a repression problem (lazy eye or cross eye) patching may aggravate that problem.

When I first started wearing a patch for extended periods of time, my visual field would contract from time to time -- real weird. I'd get tunnel vision. So definitely don't do anything that requires accurate vision (such as driving) while patching. Patching also handicaps your depth perception, which can be very important when handling sharp or fragile or objects. Keep this in mind!

Wearing a patch, since it relieves your brain of the responsibility of aligning your eyes, may reduce eyestrain if you have eye-alignment woes (esophoria, exophoria, convergence insufficiency, etc.). On the other hand, this may be a reason not to wear a patch. It's a tough call for me. Some say "worn out", others say "unexercised". Do you need rest or practice? Patching actually gives you a little of each to each eye. The

possible ramifications of patching are quite numerous, if you start thinking about it.

> 5. Does patching have to be used in conjunction with other eye exercises
> to be beneficial?

For amblyopes (lazy-eyed), patching the "good" eye is supposed to automatically improve the bad eye. However, most doctors recommend that one engage in activity that requires attention to fine detail in addition to wearing the patch.

Remember, amblyopia means that you can't see 20/20 no matter what lens you have on. The problem is not a matter of focusing ability, but of retina-brain connections.

It seems that the same logic should apply to those who are practicing their distant vision in one eye by patching the other.

Anyway, to answer the question, in order for any vision improvement "gimmick" to work -- this goes for the patch as well as plus lenses -- you have to use your brain for best effect. You have to consciously attend to details. This does not mean "straining to see" (wincing, forcedly blinking, widening the eyes, etc. that "special way") but rather being aware of what you see, comparing what you see to what you think you should see, using your imagination to reconstruct what you think is really there, observing the effect of your "guesses" on your vision (Bates said that if you imagine what your are looking at as something other than what is really there, your vision will become worse, and, conversely, if you "guess right" about the indistinct image your are looking at, the image will sharpen).

Re: "Wanting to see the world in a blurry way"

- *Subject:* Re: "Wanting to see the world in a blurry way"
 - *From:* "Linda Lee" <llee@comox.island.net>
 - *Date:* Mon, 8 Apr 1996 12:49:46
-

Eugene, in a recent letter you asked:

I dont know how subconscisly you would want to view the world in a blurry way...

and i reply - it does rather boggle the imagination doesn't it?

I think we could ask many questions of a similar nature:

Why does a perfectly healthy young woman starve herself to death even though she is surrounded by plenty of food?

Why does an attractive man stalk, rape and kill women?

Why does the young man who has been given everything suddenly decided to chop his family into bits?

Actually, "why would anyone want to see the world in a blurry way" seems quite a modest question in comparison.

I personally think that i would choose to see the world in a blurry way because the DAMN WORLD DOESN'T MAKE ANY DAMN SENSE, but that's just a guess.

Seriously tho,

I will agree that human behaviour, particularly on a sub-conscious

level is puzzling but not beyond comprehension. I think that these are ancient questions that have challenged the greatest minds since the big bang - why do we do what we do?

I tend to think that we are all living in some kind of big illusion, some large lie that denies any truth about who we really are. A friend told me recently that if you tell a lie, even a little one then you have to tell more and more lies just to cover it up. I can agree with that. I had a boyfriend once who lied about his age. After about 2 years he was in very deep. He wasn't even sure what planet he was born on. Perhaps the lies we all live with about ourselves are so massive that our behaviour becomes completely inexplicable.

But all is not lost, i think. The big question is and always has been for me, do i have free will? If i have then it is an absolute. You can't just have a little free will sometimes and not others. I can't have the free will to decided what occupation i will choose but be constricted by genetics as to vision. That wouldn't be very free, would it.

If i don't have free will, then i give up. And since i don't want to give up, i have decided that i will choose to believe that i have free will, even so far as choosing to see the world in a blurry way. That makes it possible for me to focus all my attention on changing it and not worrying about how or why i got it.

So that brings me back to the question - who am i? If i can change absolutely everything about myself, what would i change? Why would i choose to be a woman, to have a dog, to live in Canada, to talk to myself, to be myopic. What is the purpose of myopia? Would i be sitting at my computer right now talking to hundreds of people i will never meet if i were not myopic? No. Does that have value? Yes. Does myopia have value? Yes.

Questions, questions, questions and every one has an answer. All the books i have read, people i have been in touch with, concepts i have considered, all because i am myopic. Such a precious gift.

I believe that within me there is a guide leading my through this life toward my true identity. Some people call him the Holy Spirit, Destiny, Higher Power, or the Goddess Within, and some people just call him Jack, or Fred or Bertie. It doesn't matter what it's called as long as we learn to Listen and then choose. And He uses

everything - computers, anorexia, murder, myopia - everything is just another tool for finding our way back home.

Isn't that comforting.

Linda

Low/high vs. structural/functional myopia

- *Subject:* Low/high vs. structural/functional myopia
 - *From:* Elena <solusrex@soho.ios.com>
 - *Date:* Mon, 8 Apr 1996 18:06:09 -0400
-

I've resisted the temptation to get technical for as long as I could. For one thing, I did and do believe (yes Linda, you're on the right track, absolutely!) that there are a lot more pressing issues at stake than the exact number of diopters, the precise length of the eyeball, the minute changes in the lens thickness, and so on. For another, there are many technically enhanced members in the group so I assumed the above issues would be taken care of anyway. However, the important step is from technicalities to the essence, from a kaleidoscopic collection of facts and definitions to "neuralized" understanding; that's what I'll attempt to contribute to as best I can.

There are a number of issues I would like to discuss, but in order to keep my posts from elongating indefinitely like the posterior chamber of a myopic eye (while getting thinner like the back of its sclera), I'll deal with them one by one. Here's number one.

I. Low vs. high myopia is an important distinction, while functional vs. structural is not.

A Medline search of the biomedical studies yields next to nothing on myopia, but I've been able to find some research results that seems to support my idea that in low vs. high myopia, we are dealing with at least two different conditions, not with degrees of severity of the same condition. Here's an abstract:

Two different genetic markers for high and low myopia.

Olmedo MV; Munoz JI; Rodriguez-Cid MJ; Carracedo A; Gomez-Ulla FJ; SalorioMS
Department of Legal Medicine, Faculty of Medicine, University of Santiagode
Compostela, Spain. Eur J Ophthalmol 2: 196-9 (1992)

In myopia patients, Rh and acid phosphatase were typed in two groups: group1

consisted of 214 patients with low myopia (-6 D or less); group 2 of 124 patients with high myopia (more than -6 D). Statistical analysis of the markers showed a good Hardy-Weinberg equilibrium for both groups. In the Rhsystem there was a significant difference between group 1 and the control population ($p < 0.05$), but not between group 2 and control ($p > 0.1$). In the case of ACP there was a significant difference between group 2 and the control population ($p < 0.05$), but not between group 1 and control ($p > 0.25$). We conclude that the observed association between myopia and Rhsystem (chromosome 1) involves low myopia, while the association between myopia and acid phosphatase (chromosome 2) involves high myopia. Further DNA research will lead to more specific results.

The important thing here is, I think, NOT what at first sight may seem as the confirmation of some sort of genetic doom in myopia -- genetic markers predispose, not actualize -- but the fact that being predisposed to low myopia OR to high are two distinctly different molecular forecasts.

As for "structural" vs. functional: the borderline is clearly fictitious -- I suspect it originated in the fact that the ciliary was easy to observe while the extraocular muscles were not. Different groups of eye muscles may be affected, in similar or dissimilar fashion, in myopia, but they had chosen to base the whole theory on the behavior of one particular muscle that is readily available for observation. It's like losing a wallet in the dark street and looking for it under the lamppost a block away because in the dark you can't see, and under the lamppost you can.

About ten years ago, I was told, after two thorough exams before and after ten days of cycloplegia, that I had $-5,5$ D of "structural" myopia and $-2,5$ D of "accommodation spasm" on top of it. I then underwent a course of medication for accommodation spasm -- eye drops from all over the world, shots, everything under the sun, the doctor was a good friend and did a private research on my behalf. All the while I was very optimistic, thinking that functional is something that can be taken care of and that at least I will get a $-2,5$ D of improvement, hallelujah. However, the doctor was skeptical. She didn't say so at the beginning of the course but in three or four weeks, she confessed that she just wanted to give it a try but never believed that my accommodation spasm could be remedied. She said that the distinction is of purely academic interest, that for all practical purposes, the two conditions behave exactly the same way, and that diagnosing the type of myopia as "functional" means nothing at all in terms of its practical course. So what's the point of distinguishing between one and the other? Well, why not look for that wallet under that lamppost since it can't be found in the dark anyway?..

I wonder what that study I've just cited would reveal about someone like me who has BOTH "structural" and "functional" myopia, together amounting to

"high." My guess is, I would just find my molecular peers in the "high" group... no questions asked about my ciliary's ability to be noticed by ophthalmologists.

Addendum: I've seen an unaided 20/20 for the first time EVER this Saturday. I put on my +1,5 glasses while riding (not driving!!!) on the highway for an hour and a half and doing my "passenger seat exercises." When I finally removed them... hey presto. I immediately rushed outside (although the weather was yacky) and took a long walk. The 20/20 clarity was still intermittently there when I came back. It's gonna be sooooo good...

Patching "dominant" eye vs. "good" eye

- *Subject:* Patching "dominant" eye vs. "good" eye
 - *From:* carlwils@cln.etc.bc.ca (carla wilson)
 - *Date:* Mon, 8 Apr 1996 19:42:35 -0800
-

In reply to my questions on patching, Eugene asked:

>
>Whats the difference between a dominant eye and the better eye?
>
>I think one should patch the worst eye?

Using an example from a previous letter posted, to find your dominant eye, Cut a 1" hole in a small piece of paper. Find a small target on the wall several feet away. Hold the paper with the hole in it with both hands in front of your face at arms length. Site the target through the hole. Then bring the paper slowly up to your face. Close one eye then the other and determine which eye is looking through the hole at the target or get a friend to look at you to determine it. This is your "dominant" eye.

This would be my right eye, however, my left eye is visually stronger, meaning that I can see further with it.

So, which would be my worst eye?

Thankyou for all the answers I received for all my other questions.

I read Linda's VISION FREEDOM - Update with great interest. I think that she is on the right track. About two weeks ago, I really started exploring the reasons that I have chosen myopia. In fact, not just myopia, but anything from my allergies to the common cold. I have recently had a friend recommend two books to me by the same author: "Heal Your Body" and "The Power is Within You" by Louise L. Hay. She has also written another book called "You Can Heal Your Life" which is also supposed to be very good. In brief, these books are about the mental causes for physical illness and the metaphysical way to overcome them. The author herself, before she wrote the books, was diagnosed with cancer and healed herself with positive affirmations in addition to diet. Of course I can't get into the whole book, but the essence (from what I've read so far) is that almost all illnesses stem from the following: criticism, fear, guilt, or resentment in some form. For us to overcome our illnesses, we have to deal with these feelings. Linda, you are probably ahead of a lot of us because you have a very good idea of why you chose myopia. The books I've mentioned might help you in changing the thinking patterns that you have that have created this situation. I'm willing to try this in my own life in any case while at the same time continuing with V.T. I hope this might give some of you some new ideas of where to turn if you feel like what you are doing right now isn't taking you very far.

[From: mat@tekbase.metrica.com (Marco A. Terry)]

>You have "chosen" myopia? I have only read of two cases in which this was
>the cases (resulting from traumatic experiences). The myopia was psychosomatic.

One slant on the issue is that one can take responsibility for
all of one's experiences and responses.

>I really do not believe that anyone of us *chooses* to have a cold,
>or myopia, or anything for that matter. The reason you get a cold
>is purely biological. Whether it becomes or not an issue depends on
>your immune system. Your state of mind can alter the immune system.
>But that is biological too.

On the contrary, I sometimes choose NOT to have a cold and, of course,
NOT to have myopia. I then work to manifest that choice. Changing
the focus to the inverse: it would be possible to continually/habitually
choose behaviours that are conducive to myopia (assuming that there
are physical, emotional, and mental behaviours that are conducive
to myopia. I do accept that assumption). Thus, in the moment,
one makes a choice (or allows a habitual emotional pattern to guide
your behaviour). Over time, though one may not have specifically
chosen myopia, myopia may be the end result of the physical, emotional,
and cognitive choices one has made. But then there's another idea:
the body may have made it's choice independently of one's conscious
mind since it didn't like what the conscious mind was doing. There
are other interpretations too, no doubt.

I have no trouble with this, but then I don't believe that mind
is an entirely biological phenomenon.

Whatever works!

(I realize I could have refrained from sending this note, but I feel

compelled at times to defend worldviews that expand beyond the boundaries of the commonly accepted set of "scientific materialist" assumptions that are often proposed as somehow intuitively obvious corollaries of the otherwise very useful "scientific" frame of reference.)

>Yes, maybe some psychological dysfunctions but not all illnesses come from
>that.

This may or may not be true (I'm still investigating) but it does not argue against a psychosomatic or chain of choice basis for some or even a majority of myopia cases.

Just a couple of questions about diet.

I'm almost a vegetarian (I occaisionally eat fish) and I was wondering if taking extra vitamins would be beneficial to my sight and if so, what types.

Also I've been hearing about bilberry here which I hadn't heard of before. What experience have people had with this and where can I get it in the UK? Up to now I haven't seen it anywhere, but I may be looking in the wrong places.

We are happy to announce our new Web site. The contents are intended to keep you abreast of additional ways for you to continue improving your vision. In the Beyond 20/20 Vision programs I have taken the best of vision therapy, Natural Vision Improvement, Bates and simplified the behavioural vision therapy concepts. The step-by-step programs allow you to easily apply the principles at home and at work. We don't promise quick fixes or cures, however, we do offer personalized phone, fax and e-mail consultations and a variety of quality personal and Vision Educator Training courses throughout America, Canada, Australia and Europe. Enjoy and if you have any questions, my staff and I are available to be of service.

Thank you,

Robert-Michael Kaplan, O.D., M.Ed., FCOVD.

^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^

I would like to know where do you get this definition. Webster's NewWorld
dicitonary defines psychosomatic (from Psycho + Somatic) as "designating or
of a physical disorder of the body originating in or aggravated by the psychic
or emotional processes processes of the individual.." or "designating a
system of medicine.....".

If we Analyze the word: According to Websters the word "Psycho" means
"the mind, or mental process". "somatic" means "of the body, as
distinguished from the soul,mind or psyche.." or (biol) "of the soma"
or " the outer walls of the body as distinguished from the viscera"
The words intended use (as far as I know in psychology and medicine)
is usually in reference to a disiease in which no biological (external) causes
can be found and that is cured using psychological methods.

I think that a lot of good research is going on now (along the lines of Barbara Brennan's work) on expanding our knowledge of human energy systems and on effecting health by energetic/cognitive/emotional/imaginative methods in addition to or instead of bio-chemical methods.

[Elena:]

>> We've created a language of false and empty distinctions and have

We could say that this defect is the result of scientific materialism. But it's more the result of human thinking from within any paradigm. Some adherents of scientific materialism have superstitions just as some adherents of (fill in the blank: taoist mysticism? spiritualism? reiki?).

[Marco:]

>A disease can be (I am sure there are more causes) - bacteriological,
>from a virus, from certain proteins, cause by the ingestion of certain
>substances, caused by malfunctioning or corruption of body organs et
>al. or it can be produced by the mind in response to something

>*BUT* that does not mean that all colds are from the mind.

What seems to be at issue is the type of causality invoved.
To take the example of a biological contagion: One might argue
that the energetic/emotional/cognitive choices that place one in an
immunologically depressed state such that one is more susceptible to a
given infection is a more fundamental level of causality that can
be addressed by some therapeutic means. If someone has been able
to cure their case of cancer by using non-standard, "metaphysical" therapy,
then they ought to write a book about it. Some of us might find
the information useful.

I heard that there is way to freshen ormoisturise your eyes.

Here is how it follows:

- 1: Cup your hands with water.
- 2: Place a bit of water in your eyes so you can feel some of the water entering your eyes.
- 3: Do this for both eyes.

There is also another way to reduce myopia. It is a yoga exercise.

- 1: Go into a dark room
- 2: Light a candle (small)
- 3: Place it 7 feet away from you eye level
- 4: Have a glass of water ready

Now to start the exercise

- 5: Stare at the candle for as long as you can without having to blink. It doesn't matter if tears form. Once you do blink try again. Do this three times.
- 6: Then after the third time close your eyes and dip your hands into the water
- 7: Brush the water on your hands on to your eyes
- 8: Brush it three times.

I am not sure if this woks. If anyone knows about this method or has researched it

please write back. Thank you

>can be found and that is cured using psychological methods.

I don't blame Webster of course -- a dictionary mostly reflects (and only occasionally shapes) what's going on in the language, while the language is both a reflection and a shaping mold for what's going on in the "psyche" of its speakers.

Let's assume for instance that a "human" is really something that can be successfully divided into "psyche" and "soma" -- where do we find ourselves if we're able to draw a demarcation line along this hypothetical border? -- which is something so easily accomplished in the language of "psychology and medicine" but so elusive in reality that no one has ever observed anyone successfully perform this operation any other way but verbally? Think about it. We cut one clear from the other... and we're right in the warm embrace of metaphysics, religion, mysticism, etc., supposedly so despised by "real science." We do this and we're right where they divide a human being into a material body and an immaterial soul, right where science abhors to tread in the first place. And why are we here? Because we've just performed a pseudoscientific operation and have consequently found ourselves outside the realm of science -- and it doesn't matter whether we think science itself is severely limited or, alternatively, everything BUT science is fiction -- it doesn't matter, we're outside ANY science with this "psycho" floating away from "soma" at some obscure point of no return. Because in real science, you won't be able to find the exact place where one ends and the other begins. I mean, not in this world, not in this reality, not in a human hospital for human patients you won't. I'm not prepared to argue philosophic or religious or whatever aspects right here and now -- but staying well within the corral of "real science," we're indivisible into body and soul. One human, indivisible... and whether under God or not is a separate question altogether.

>A disease can be (I am sure there are more causes) - bacteriological,
>from a virus, from certain proteins, cause by the ingestion of certain
>substances, caused by malfunctioning or corruption of body organs et
>al. or it can be produced by the mind in response to something
>of an emotional nature. You *may* be able to think a cold and get one,
>*BUT* that does not mean that all colds are from the mind.

Of course not. A disease can be caused by anything you dislike. By "you" I mean your psyche AND your soma -- they can't dislike ANYTHING separately. They are simply not equipped, biochemically, with latches and keys that would allow your body to get sick and your mind not to participate, or your mind to get, say, depressed and your body to be clueless about the fact and jump of joy. By "your mind" I don't mean the 5% of your (and anyone else's) mind capable of cognition; that's possible of course, you get the flu and you "cognize" that you feel like sh...t, but that's not necessary. The overwhelming majority of functions your mind performs are not cognitive functions. The overwhelmingly larger part of your mind -- or 95% of your "psyche" -- will know anyway you've got that bug, or have had one drink too many. And your immune system, part of your soma, will, on the other hand, know if you're heartbroken from a failed relationship, or disappointed at not getting that promotion you've hoped for.

And your eyes, the very place where the connection is the most intimate, the very spot where one transforms into the other at the speed of over a million electrochemical impulses/bits of information per second -- material into abstract and back, one million times per second -- more than anything else make the dividing of "human" into "psycho" and "somatic" transcend ridiculous.

"Psycho" and "somatic" don't get sick separately and don't get well separately. They don't know how.

a good point from Mark, often, i think, overlooked, when using the Louise Hay line of thought:

>Over time, though one may not have specifically chosen myopia, myopia may be the end result of the physical, emotional, and cognitive choices one has made.

This reminds me of the phrase - "beware of what you ask, you may receive it." Just recently i was thinking of the Greek goddess that asked for eternal life. She forget to mention that it would be nice to be healthy as well. Her lot in life turns out to be, eternal misery.

So long for now,
freda

All the way as I was reading your message I was getting ready to slam you as what you wrote I consider to be next to nonsense. But then I reached the Addendum. Gosh, is that true?! Even when I discount your reported 20/20 to 20/40 it still looks amazing. If you started somewhere from the neighborhood of -8.0 D nine months ago and are now able to see 20/20 unaided even for a brief period of time, this is a great achievement. You must be special - in mind and body. I think nobody else on this list has yet reported a progress that is beyond the limit of about 1.50 D that I think is achievable (I posted this some time ago).

So, please tell us more about what you do.

I'm not speaking as an expert, but I experienced my first "clear flash" two days after taking "Eye Bright" from Healthcrafts. This contains Vitamins A D and B2 plus extract from the Eyebright herb (*Euphrasia* spp). I've been too excited to stop taking it and see if the clear flashes disappear. (Yes, a middle-aged middle-class-ish Englishman can get excited but don't tell anyone) Its possible that the "clear flashes" occurred as a result on a few months of Visual Therapy and not the pills.

Can someone help me formulate a response to this view that eyes may learn to accommodate - but are structurally still not 20/20... I'm continuing with research helping my daughter do a I-Search research paper in high school biology. I posted her questions on this list. I also sent them to many web sites. I've been trying the exercises since I found the I_see list and have had improvement. I now wear my daughter's glasses since my glasses are too strong.

THANKS For you input.

Kath

>>>1. Why do objects become clear when they are close to the myopic eye?
>>Sorry. I don't quite follow.

>

>This is aimed at the structural changes between normal eyes and myopic

>Do the eye forget how to constrict or relax?

The structural change is that the myopic eye is elongated compared to the normal one.

Specifically, the vitreous chamber length is increased (distance from the lens to the retina).

The lens and cornea are no different from normal eyes.

Thus, myopia is not due to a "forgetting" of lens relaxation, but due to an excessive growth of the eye.

>We've read the "myopic eyes focus beyond the length of the eye..." but what >does that really mean?

The focal point of a myopic eye is in front of the retina.

I'm unsure of the context of that statement you quoted, but it has recently been found that myopic children who have progressive myopia do not focus

accurately through their spectacles.
Their focal point falls behind the retina.
As a result, the eyeball tries to elongate to match the focal point to the
retinal position.
(hypothesis based on animal experiments).

>We've gone to a CK doctor - he's expensive and has to have 5 levels of
>height in the eye's structure and when the vision is as poor as ours there
>is no guarantee that it will get to 20/20 and one must still wear the
>'flattening' contact periodically like a retainer for braces.

I'd avoid "CK" or orthokeratology.
Ref: Berkely orthokeratology study - no long term benefits in retarding the
progression of myopia. This was a long-term NIH sponsored project, with a
convincing outcome.

>Can I read this somewhere - or site it in the paper?
It's published in Chinese. A colleague of mine in Taiwan worked on this for
his Ph.D , which is published in Chinese. Prof. Luke L.K. Lin

>>Bates method not shown to be successful.
>Likewise, I'd really be grateful for information.
>I was so excited to hear of the prospect of improving my vision I started
>exercising my eyes and for the first time in my life I reversed the trend.
>I didn't want to wear my contacts - I put on old glasses with 10 year past
>subscription! and began looking for my other glasses - the lenses are too
>strong!

It's no longer being investigated.
The only paper is in Bates original book - Better Sight Without Glasses.
The comparable technique in China/Taiwan is palming or ocupressure point
massage.

Again, no documented positive long-term effects.
You must realize a distinction between clearer vision from these methods,
and a real change in the refractive state of the eye (or axial length).
The latter are the hard evidence of a real change in the eye.
Vision can be affected by many factors, including transient changes in
accommodation.

I also got a message from Linda who "didn't get the middle" of my post. The reason I cited the Spanish study and some (but not all) of my thoughts around it was to 1)satisfy my petty ego with a little scientific proof of my old theory -- "all myopia is not created equal;" 2>alert someone considering PRK (for instance) or parenting a myopic child to the existence of a DNA-encoded FORECAST of the tendency of his/her myopia to progress indefinitely OR to stop anyway; while at this point it's not something that can practically influence decision-making (for lack of availability of specific genetic profiling), it may become so in the future; 3)argue low pragmatic value of the structural vs. functional juxtaposition on both molecular and functional levels where it ceases to exist; 4)hopefully discover a lurking biochemist among the members of the group who would suddenly get and share insight as to what can be done in terms of diet, supplements, etc. to modify one's "somatic behavior"-- something I've had some success with after questioning a couple of knowledgeable neuroscientists (who unfortunately have no special interest in refractive error problems) and reading some excruciatingly difficult (for an M.A.) books on neuroendocrinology of perception. I feel quite desperate because I don't know nearly enough and I think it HAS to be studied, it's a big part of the puzzle; 5)remind the proponents of the "genetic" theory of myopia that no decisive genetic proof (which would be a specific gene) has been found in any studies specifically designed to probe into genetic sources of myopia; correlations, markers, etc. are just what they are -- proof of

potential, not of imminence.

Does it still sound like nonsense? I try to avoid talking nonsense as best I can, but of course I might not always succeed. However, the instances where what I'm expressing is an alternative/conflicting opinion should be exempt from the category of "nonsense." Not thinking what you think doesn't make my thinking nonsense. Different things make perfect sense to different people. This of course goes both ways.

Coming soon. I'm not holding back a trade secret -- I wish I had a simple straightforward "answer" like the Vision Freedom guy (btw Mr. Severson, you promise not to be my penpal and then keep on sending me messages, a promise is a promise, please stop, OK?). Do this and this and it works like a charm. But it's really a paella rather than a hard-boiled egg, if you know what I mean. Damn it's not easy to explain. Nothing of what's going on with my vision is "by the book," not even by the Bates et al. I have pieces of paper all over the place with captured "translations" into verbal of what I'm doing as nonverbally as can be -- every time I feel I can formulate it I write it down. But it needs to be organized before I attempt to convey it to others. I will, I promise.

Hello, I am a vegetarian (I do not eat red meat, fish or chicken, but I do drink milk and eat eggs). I was wondering if I am missing any special nutrients crucial for eyesight by being a vegetaian. Also I was wondering if anyone could fill me in on what billberry does to help the eyesight. In addition:

1. I recently went out and bought a pair of plus lenses (+1.5, my eyesight is currently -1.75 -1.75). When exactly should I be wearing them , and should I only use them for close up work or also for longer distances.

2. I have a 17" mag inovision monitor with a .26 dot pitch. I use my computer about 45 minutes a day. Using the adjustment knobs it is possible for me to shrink the screen size down to 14". Should I use my monitor with a 17" screen or a 14" screen, I have heard that both ways are beneficial.

Eugene, (Jack?)

First of all, -1.5D of myopia CAN BE functional. Since you are still in your teens, your prospects are very good.

Here's another tip. Get out and move your body a lot.

Take walks.

Enjoy the outside.

Even if this means not reading I SEE!

I used to wear -1.5D glasses and I now enjoy sparkingly clear vision when I am outside in the daytime. Even my night vision is very good without glasses. I'm sure you will be able to achieve at least this much.

Frankly, Eugene, if it is true that you cannot overcome your myopia, I think I'd might as well close down this list.

All the "greats" of vision improvement have admitted that high myopia in

people who have worn glasses for long periods of time is much more stubborn than the lower degrees. All of them say that having worn glasses makes it much harder to go back to normal.

You are a classic case of a myope who has an excellent chance of recovering complete distance vision capability.

Eugene, if you can't do it, no one can.

Now Eugene, you said last week that you were seeing an eye doctor. Now did you? If so, what were the results (and procedure of evaluation)?

Subject: Diet and eyesight

Just a couple of questions about diet.

I'm almost a vegetarian (I occaisionally eat fish) and I was wondering if taking extra vitamins would be beneficial to my sight and if so, what types.

Also I've been hearing about bilberry here which I hadn't heard of before.

What

experience have people had with this and where can I get it in the UK? Up to now I haven't seen it anywhere, but I may be looking in the wrong places.

I've been following along for some time now, and have noticed that when the subject of the eye structure of a myope comes up, someone points out that the shape of the myopic eye is **not** round. I know this is typical, because my eye doctor told me once that he'd never before seen anyone as myopic as I was who had perfectly round eyeballs. So what I'm trying to figure out is: WHY the heck am I so nearsighted? I have no astigmatism, but have discovered (no thanks to my eye care professionals) that I do NOT have binocular vision. Unless I'm moving (walking, driving, etc.) I have to deliberately move, at least a little (or constantly shift my eyes), to see clearly. So it's that and myopia.

I do tend to enjoy close work (crafts, etc.) and spend as much time at my computer as my schedule will allow. Close up, I tend to look at things with only one eye (I just discovered this), but that doesn't work with distance vision! My muscles have never loosened up easily; despite several years of gymnastics I was never able to do the splits, and I have to warm up before I go for a walk. Could it be that my eye muscles are yanking my eyes in slightly odd directions? Dad's got the same thing. If my lenses are too convex, can that be remedied directly without surgery? Any hypotheses will be absorbed with utter fascination. Thanks!

Thanx Alex!, I just came back from 5 hrs of tennis/basketball/handball
came back and could see the 20/40 with my left eye, right cant see the
20/100 (maybe barely).

I dont use computer alot, i only read ISEE msgs ;) I like to stare alot
in to the distance, and mostly use my eyesight (which is pretty good
outdoors, alot of clear flashes). When I do read ISEE i use the +1
glasses.

I have never worn glasses, going to see the OD on April 23 (at 5pm). My
results as I have tried to figure out how much myopia I have is this: I
can read 82cm before the text becomes slightly warped with the left eye,
and 61cm with the right eye. possibly -1.25L, -1.75R.

My other concern is should I ask the OD to try cycloplegics? My second
(most important) concern is the night vision. I heard that night vision
may be slow to recover, even if I do see 20/20 with bright sunlight. My
vision is pretty bad. Cant even spot a face across the street, if its
pitch black (ie with lights).

Have an eyes day ;)

Binocular Vision Exercise

- *Subject:* Binocular Vision Exercise
 - *From:* Alex Eulenberg <aeulenbe@indiana.edu>

-

Here's a NEW exercise for binocular vision.

Actually, it's for acuity too, but I noticed amazing effects on 3-D perception and the ability to see objects "moving" in the background as I walk around.

Like all eye exercises, this is best done outside. Also, if you have any doubts about the safety of this exercise for your particular eyes, consult an eye care professional.

The first part should be familiar to those who have done "thumb shifting"...

Looking at a distant object, hold your thumb in front of your nose. Now the "distant" object may be several hundred feet away, or it may be a meter away or even less. The important thing is, when you look at it, you should see two "thumbs" in front of it. Now, move your thumb left or right so that the distant image is centered between your two thumb-images. Tilt your head, if necessary, so that the two thumbs are upright and level.

Now, with the other hand (the one that's not sticking up the thumb), cover one eye. Do not move your head or your thumb at this point!! Notice that the thumb that remains is on the same side of the distant object as the eye that you just covered. So if you're covering your right eye, you will now see one thumb to the right of the distant object.

Now, shift your gaze to the thumb without moving your head or your thumb. You may feel tempted to move your thumb or your head, but tell yourself that the thumb is in your center of focus, and that the distant object is to the left (or right, as the case may be). Convince yourself that the thumb is actually in the center of your visual field. You know that it must be, since you're looking straight at it, and it is directly in front of your nose.

Now look at the distant object, and do the same thing. Now the distant object is in your center of focus. Convince yourself that this is true.

Shift back and forth, or rather, left and right, between distant object and thumb.

Repeat, covering the other eye (and using your other thumb -- this will probably be more convenient).

Finally, put it all together, doing it with both eyes simultaneously (classic thumb-shifting).

If one eye is "dominant" you will probably encounter much resistance when doing this exercise. If you feel pain, discontinue this exercise.

After doing this for a minute or so, I found that 3D perception was remarkably improved, as was acuity.

I have a feeling that this is very similar to the "muscle treatment" that J.P. Walker referred to in his "Changes in Corneal Astigmatism" paper. For more details, see this paper at

http://ezinfo.ucs.indiana.edu/~aeulenbe/i_see/parker.html

I would appreciate any comments (posted to I SEE, of course) from people who have tried this exercise.

> WHY the heck am I so nearsighted? I have no astigmatism

First of all, let's get a few things straight. When it is said that the myopic eye is "elongated" this refers to its shape front to back. Eye doctors practically never measure the front-to-back elongation of your eye. If they do say you have "long eyes", it's probably because they measure your myopia and then conclude from that that your eye must be elongated. In very high myopia, however, the fact that the eye has been lengthened of the eye can be directly observed. At the retina, there is often evidence of stretching known as the "myopic crescent."

Now when your doctor said your eyes were perfectly round he only could have been talking about the shape of your cornea, the fact that you have no astigmatism. Astigmatism refers to a bulging in the curvature of one's cornea along one "meridian" or diameter-line of the cornea at a certain angle (the "axis" of astigmatism).

>, but have
> discovered (no thanks to my eye care professionals) that I do NOT have
> binocular vision. [...]

> Could it be that my eye muscles are yanking my eyes in
> slightly odd directions?

What it sounds like to me is the following. BECAUSE you don't use both eyes at the same time, your eye muscles AREN'T yanking your eyes in the way that normally produces astigmatism. To keep both eyes aligned is a tricky task. By eliminating the binocular factor, you give your recti muscles (the ones that make a cross centered on your cornea) the

opportunity to concentrate on creating that "perfect" tension around each eye.

> Dad's got the same thing. If my lenses are too
> convex, can that be remedied directly without surgery? Any hypotheses will
> be absorbed with utter fascination. Thanks!

Well, you might try the "binocular vision exercise" I just posted. Check with your doctor if you think it might be "risky" for you. I actually predict that if you learn to use both eyes at a time, you will actually CREATE astigmatism, at least temporarily. Your eye doctor will of course say that this is impossible.

For some more insight into the matter, see...

"Changes in Corneal Astigmatism"

> Thanx Alex!, I just came back from 5 hrs of tennis/basketball/handball
> came back and could see the 20/40 with my left eye, right cant see the
> 20/100 (maybe barely).

I have found that vigorous exercise sometimes makes my vision better, sometimes worse. There was an article in an old optical journal about an otherwise normal-eyed optometrist who became myopic after bowling a while. He carried around some myopic (minus) lenses to put on after a few rounds. If your body gets a workout, your eye muscles will also feel the drain and tense up.

Some ideas:

- 1) Rest your eyes by palming for a half hour or so after each workout.
- 2) Eat foods to replenish your store of vitamins and minerals and nourish your aching muscles.

I have had best luck with brewer's yeast, which contains protein and lots of B vitamins, as a food supplement to counteract muscle strain.

> I dont use computer alot, i only read ISEE msgs ;) I like to stare alot
> in to the distance, and mostly use my eyesight (which is pretty good
> outdoors, alot of clear flashes). When I do read ISEE i use the +1
> glasses.

Of course Bates would say that you shouldn't "stare" into the distance. Rather, let your eyes wander. It is not important to make out every detail, however. "Trying" to see distant details causes more strain and more myopia.

> I have never worn glasses, going to see the OD on April 23 (at 5pm). My
> results as I have tried to figure out how much myopia I have is this: I
> can read 82cm before the text becomes slightly warped with the left eye,
> and 61cm with the right eye. possibly -1.25L, -1.75R.

You say "warped". Sounds like astigmatism. Good for you that you noticed that the warping depends on the distance of the object. Sounds like functional astigmatism. My bet is your doctor has never heard of such a thing and will want to prescribe you cylinders.

> My other concern is should I ask the OD to try cycloplegics?

There are pros and cons for asking for cycloplegia.

The pros are, if you are given cycloplegics, and the verdict is "myopia", and you subsequently rid yourself of myopia through Vision Freedom (or other method), you will be doing a service to the cause of better eyesight without glasses. You will be offering modern proof that the distinction that eye doctors make between functional and structural myopia is problematic. Most professionals assume that (or act as if) cycloplegics remove the factor of functional myopia, even though this used to be contradicted all the time in the optometric journals. Unlike MD's (ophthalmologists), optometrists used to not be allowed to use those drops (in many states, they still can't). Now, many OD's use these drops too, and the criticism has disappeared from the journals. The last article that I am aware of that dealt with this issue was written in 1972:

* Ludlam, William M., Stephen S. Weinberg, Chester J. Twarowski, Diana P. Ludlam. 1972. Comparison of Cycloplegic and Non-Cycloplegic Ocular Component Measurement in Children. American Journal of Optometry and Archives of American Academy of Optometry 49, 805-817.

The authors concluded that refraction with cycloplegia is actually LESS reliable than without, given a competent refractionist. I add that modern scientists have ignored their recommendation. In order for a myopia study to be considered "scientific" nowadays, cycloplegia MUST be used. Today's scientists still cling to the myth that cycloplegics always "relax accommodation", even when the actual muscular actions underlying accommodation is still a subject of debate. This is unfortunate, since it makes the experiment more expensive and cuts down on the potential number of subjects.

However, Eugene, YOU know that you do not have perfect distance vision, and you don't need any cycloplegics to prove this to you. Cycloplegics

have NEVER been advocated as a means to "cure" ANYONE of myopia, except in as much as they temporarily neutralize the condition DURING THE EXAMINATION ITSELF. Cycloplegics have been used to apparently slow the progress of "progressive" myopia, but when the use of the drops is stopped, there often occurs an "accommodative binge" and the patient becomes myopic all over again.

In no other area of medicine is a part of the body routinely paralyzed. With cycloplegics, there may be side effects, including allergic reactions, an indefinite reduction in your ability to focus close up. You'll certainly have to wear sunglasses after the examination, and you might not be able to read for many hours without reading glasses (plus lenses).

On the other hand, it might be an interesting experiment to try accommodating while under full cycloplegia. Bates said that it was atropine, the most powerful cycloplegic, did not always paralyze the focusing muscles.

The charge that cycloplegics permanently reduce the ability to focus up close has been leveled in the optometric journals. Some say that the effect is permanent. Right now for you this may not be a problem, but it could be in older age. If you do opt for cycloplegics, note your "near point" as well as your far point before and after cycloplegia. My guess is that if you can exercise your way out of myopia, you should be able to exercise your way out of a cycloplegically-induced reduction in accommodative range.

Bottom line: cycloplegics are not necessary to determine to you the extent of your myopia. Use them only if you want to prove something to the world about the nature of cycloplegia and its relation to myopia, if you intend to prove that structural myopia, as defined by a cycloplegic examination, can be overcome.

Here are some random tips: Paradoxically, the more time I spend in the sunshine, it seems, the better my night vision becomes. This has been my experience, and one other I SEE member noted a correlation. Bilberry, of course, is famous for improving night vision. Vitamin A, as everyone knows, is also essential for the retina's ability to react to light. In fact, another word for vitamin A is retinol. Vitamin B complex is also

supposed to help with problems of light sensitivity. Increasing your daily intake of sunshine, vitamin A and B, and trying out bilberry capsules, may improve your night vision. Use your good judgement and find out what works for you!

A trick to make the convincing part easier -- might work for those familiar with visualization techniques: imagine that your eyes have exchanged places -- your right eye is looking at the world out of your left socket, and vice versa. Sounds crazy but now that I've read some NLP stuff I know why it works -- it breaks the habitual (and inefficient) pattern of visual representation. This one, in particular, may create binocularity quite effortlessly if you make a habit out of looking this way for a few minutes every day. Not necessarily while doing exercises -- just walking down the street, for instance, or even watching TV.

> If you feel pain, discontinue this exercise.

A few months ago, no matter what exercise I was doing, it was painless only as long as it didn't work. If I got a clear flash, whether "induced" or spontaneous, it was incredibly painful. Incredibly. I couldn't believe it because I was really doing nothing -- not squinting, not widening my eyes, not straining, not staring -- just looking the non-habitual "way" -- and the moment it worked, it hurt. I wrote to i-see at that time and someone reassured me. The reassurance consisted in telling me that this person also felt pain but later learned to eliminate it by correct blinking. It took me some time to figure it out but eventually I learned to close my eyes for a few seconds (or longer) the moment the pain started, even if it disrupted the much-sought-for clear flash, and not chase or grab the clarity at the

cost of comfort. It did take a few months before the clarity/pain reflex was gone. I wonder how common this is.

I think you should be sure and be very consistent with using reading glasses for all close up work to prevent excessive tone in the ciliary muscle. If you're not improving, you need to go up on the strength of the positive diopter lenses, do more outside work or play, etc. You've got the basic concepts down I think. It's like a weight loss program. If you're not loosing weight then you need to exercise more. I've had lots of patients complain that they are watching their diet and exercising but still can't loose weight. Then you get into specifics. They're still eating meat, cheese, whole milk and walking around the block once. And they are surprised or upset that they don't loose weight and they act like it is just impossible. But they just need to go vege and work up to 20-40 minutes of aerobics until they're sweating 3-5 times a week for months to years.

Surprise!! Your best bet is to nip the problem in the bud when it first starts. I'm really wondering how the medical profession can explain what they've done to people with these negative diopter lenses. It just makes the problem worse. They're a quick fix that make people go blind. If I'm wrong about that I'd sure like some specialist in the field to reassure me that this is not the case.

Hi - I am one of the invisible women on the list. I, too, believe that there is a somatic component to my myopia/astigmatism. Before I ever heard of VT I discovered Louis Hay's "You Can Heal Your Life." I began by noticing how closely physical symptoms of friends and family coincided with attitudinal stance. After I became more comfortable with being "imperfect" myself, I took notice of MY symptoms, and made changes in my thoughts to relieve them. I effectively cured the recurrent, blinding headaches I used to have, simply through mental affirmation.

I have experienced a number of clear flashes this last week. The reason? I think it is because I have been able to clearly and calmly state my beliefs, even when people who are important in my life disagreed. That used to scare me - I feared rejection, or damnation - but found it is possible now to agree to disagree, yet remain in relationship (I hope my daughters were paying attention:). Since I am more able to accept myself as I am, maybe others are finding it easier, too.

I enjoy reading the less technically oriented posts, too.

I have also experienced pain with clear flashes, although I wouldn't call it intense pain. It's like my eye(s) is pulling hard. Unfortunately, after I close my eyes, I almost always lose the clear flash.

Well, I think talking to an ophthalmologist would be very frustrating, and has been for me. However, other primary care physicians seem to be more open. I took some information to the California Academy of Family Physicians meeting this spring. The information was about the research of behavioral optometrists. I think all my patients who become myopic should be informed that there is more than one school of thought on myopia, I should be able to inform them of the schools of thought and give them referrals to various practitioners in the area for whatever treatment option they choose. After reviewing the information myself, I would strongly encourage vision therapy and discourage the use of negative diopter lenses. I think all family physicians should be aware that the debate is still on regarding myopia. Most of the younger ones I have spoken to had no idea there was another school of thought. The Academy acknowledged that alternative treatments may be valuable. This has not been acknowledged by any ophthalmologist that I know of. I have submitted an article for one FP publication and we shall see. I think if physicians or other health care professionals would look at the information without letting the ophthalmologists do all the thinking, we'd have a very different standard of care. All it takes is a few articles in some primary care journals to get this debate into the medical community. No one should have corneal surgery without full informed consent. The state of affairs is really sad but I hope to put in my 2 cents to see that it changes. I'd like to see some O.D.s write up some stuff for publication in pediatric or family practice journals.

I would just like to get really off track and point out that all this stuff is really, really complicated. To say that a cold is caused by a virus is a partial truth. Just something as simple as a cold is multi-factorial. If the virus is present, then why do only 3 out of 5 people in a household get a cold? You need the virus, a susceptible host, the process of transmission, and an active enough infection for symptoms to be manifest. The immune status is a major factor and the mind has a tremendous effect on the immune system. My theory is that the flu season is actually caused by the Holiday Season, not the presence of viruses in the winter. If we would slow down like we are supposed to near the winter solstice, hibernate a bit, cut out the cards, the shopping, the piles of food, cooking, cleaning etc, any uncomfortable family gatherings, we'd all feel a lot better. I personally would make exceptions for little kids, but I feel better without all that baggage.

Supposedly, the flu season is not caused by cold weather per say but by more people being indoors. Well if that were true, you would expect the onset of the season to be soon after the school year starts, because that's when you have the largest shift of people going from spending a lot of time outdoors, to staying indoors. But that's not when it occurs. My bottom line, I think myopia is much more physical than emotional but I am open to learning new things.

I too have those brief moments of 20/20. They get more frequent and longer lasting. I was -4.5 L, -4.0 R. I have had several measurements showing a drop of one diopter bilaterally, but I can tell I have not yet dropped the second diopter but I am working on it. I think it will take time and effort to stabilize my eyes at that 20/20 point.

I couldn't agree more!!! I RAGE, RAGE against those stupid, unfeeling, mechanical, unimaginative optometrists who prescribe minus glasses to children utterly convinced that they are doing good by correcting an error and enabling the child to see well and rejoice in good vision.

Miserable bastards. My mind can't fathom it how deluded modern optometrists can be. I want to bring in one other factor - parents/teachers. It is sometimes parents (or teachers who alert parents) who notice that their child is squinting and cannot see well who hurry to take their beloved son or daughter to an optometrists to right the wrong. I for one got my first pair of glasses at 10 after my father noticed that I could not read the license plates of cars while he could. I measured -1.25 D bilaterally the first time. Later on, he was scolding me for not using my glasses to read (my form of plus lense therapy). I am unfortunate to have had no support and understanding from my parents with regard to visual matters. I feel happy that I can be very different with my children.

So, widespread proliferation of the view of preventability of myopia and its reversibility if acted early will help in making the world less myopic. However, I continue to claim that at a later stage (when structural changes occur) myopia remains preventable, but largely not reversible. At this point I cannot dump everything else in my life and set up an international foundation to popularize this view worldwide (Alex is doing a good job in this direction). But a world changing, all-out effort will require long and

not easy to set up studies (Dr. Granet reported recently on sci.med.vision that one such study was in the pipeline). You can't convince the establishment if you don't have the necessary studies. I don't approve of some members on the list (mostly females) speaking negatively of "numbers". If what I/we stand for is right the numbers will come out right.

This topic was extensively discussed in a thread I started on sci.med.vision last October - "Myopia should not exceed 3.0 D". If you have a spacious newsserver you can try digging the tread out with DejaNews.

Regards,

Stefan

Plus lens therapy, revisited (a brain's perspective)

- *Subject:* Plus lens therapy, revisited (a brain's perspective)
 - *From:* "George Tohme" <PolySoft@msn.com>
 - *Date:* Tue, 16 Apr 96 10:02:02 UT
-

My question is this: what benefit is there for wearing plus lenses for long distance viewing (ie. other than for close work)?

I'm just thinking about this not from an optical point of view but from the brain's. What is the difference between a blurred image seen by the naked myopic eye and one produced by a myopic eye (-2.50) and probably made more blurred (at least in my case) by the plus lens (+1.00) ?

How would the brain know (since it is what makes the muscles adjust) what to do?

The same question applies even for close work with plus lenses while pushing the objects too far beyond the person's field of vision.

george

To K.Baker's daughter-sorry, I accidentally erased your address

Do you consider acupuncture, reading glasses, or biofeedback natural? I'll try and give my opinion on #7. I am a family physician. I read a book by a behavioral optometrist and started doing focusing exercises (also recommended by my yoga teacher) and went down on the prescription of my lenses. I dropped 1/4 of my prescription in 6 months. I then visited a behavioral optometrist who teaches at the local school of optometry who gave me several journal articles so I will give you some of those references. If you want more, let me know.

I have tried to discuss this subject with ophthalmologists but have yet to get a satisfactory explanation for the etiology of myopia, the cause of my improvement and the reason why I heard about this vision therapy from a book in a gift catalogue and not from an M.D.. I now know there are natural ways to improve myopia. I believe anyone who works at it can improve their vision. I have started an acupuncture series. In this doctor's office there is a poster which lists those diseases that the World Health Organization considers to be responsive to acupuncture. Myopia in children is on the list. I will be looking for the studies which back this up.

Here's some references for you:

I liked your post very much, especially

>My theory is that the flu season is actually caused by the Holiday
>Season...

This thought is timely for me since I've had a preoccupation lately with assuming responsibility for everything that happens to me or around me (not control or self-absorbed fits of blame, but responsibility.) I plan to be more vigilant this winter. Winter is a great time to work, watch, and wait.

To link this more closely to vision improvement, I should mention that when I remember this attitudinal stance and commit to it with my full intent, I experience a slight increase in perceptual clarity and a greater sense of involvement in what is happening at the moment.

I have this Calvin and Hobbes cartoon that illustrates my understanding of glasses and surgery. I got the lenses when I was about 8 and was soooo excited because I suddenly saw so clearly. Calvin is throwing up a water balloon into the air. He catches it and it pops all over him. He's soaking wet and says something like, "How come an idea that looks so good at first turned out to be so retarded."

I got one ophthalmologist friend to really take time and sit down and discuss my concerns with me. He told me I should have been instructed not to wear the negative lenses while doing close up work as this could cause accommodative spasm and worsen my myopia. If I was told that it went in one ear and out the other. I wore those things from the moment I woke up until going to sleep and did tons of reading with them. I don't have the records so I do not know how my eyes changed in grade school but I know they didn't change much after high school. I did have astigmatism come and go on exams but I never noticed it subjectively.

After that conversation, I called a friend who is a cellular pathologist (this is a specialist who knows a whole, whole lot about lots of stuff that would fit on the head of a pin). Let's just call him Dan Q____e. He's myopic. I wanted detailed info on the ciliary muscle, but he couldn't get me the info I wanted. I asked him if he had been told not to wear his glasses for close up work. He said "No, but I was told to be sure and wear the lenses regularly before each doctor visit" I asked why that was. He said, "Because if you don't wear the glasses, your vision gets a little better." I said, Dan, Duh!!!!

That was the end of the conversation. I think he still thinks I'm in dreamland because all these really, really smart doctors couldn't have made such a mistake.

When I was reading Kaplan's book I asked a friend in education if it was true that brains were four-eyed or if that was just a stereotype. She said it was true according to the education literature. She was prescribed lenses in jr hs. She said she fought with her mother for a year as she hated them and refused to wear them. Her mother insisted, as it was "Doctor's orders". Her eyes were measured a year later at 20/15. The second doctor explained that the first must have made a measurement error.

Then I started taking histories on all my patients who came in with glasses. Lots with new onset of myopia as adults. My father (another family physician) said my oldest brother had a diagnosis of myopia in his teens which reversed the next year. He too refused to wear the glasses. So I'm still sitting here in shock that I was turned into a geek and almost had my eyes cut on and this medical stuff is full of contradictions but all these really smart people still buy into it. I need some tylenol.

Dear George,

Neither of my two favorite herbal references gives any warnings about eyebright. They are usually very thorough in this respect. (One is "The Herb Book" by John Lust, and the other is "Likarski Roslini" ["Medicinal Plants"], a comprehensive Ukrainian herbal encyclopedia.)

As for bilberry, the Ukrainian book says it may cause constipation and worsen the condition of people with weak intestinal peristalsis.

I think I'll mention their other effects too while I'm at it.

Eyebright is astringent (helps against diarrhea), reduces inflammation, and lowers blood pressure. Its infusion is used for cold symptoms and hay fever.

Bilberry is astringent, antiseptic, good for hypochromic anemia, gall bladder stones and kidney stones, gout, rheumatism, eczema, psoriasis, skin rashes, atherosclerosis, hypertension. Bilberry leaf is used for diabetes, all kinds of kidney and bladder diseases, and enterocolitis.

The Ukrainian book also contains a long list of chemical constituents for bilberry and references to studies (in the former SU, herbalism was a respected part of medical science as you may know).

Hope this is helpful.

Ari

Perhaps some of you know Richard Allen, a behavioral optometrist practicing in England and an occasional contributor to sci.med.vision. I've had some worthy private correspondence with him and asked him for permission to share it with I_SEE. He gave his consent and I am gladly posting his main reply (I have cut out some unessential - related to computer connectivity problems - detail).

Richard Allen's views about myopia very closely match mine.

Stefan

I think you'll find that my opinion is shared by most behavioural optometrists.

In my experience (and with my current understanding) myopia can be cured TO A DEGREE. My current feelings are that more than 1.5 D of myopia is probably set anatomically, and there is no way a patient is going to get to read 6/6 (20/20) without some form of aid. Some of my (American) mentors (especially Dr Paul Harris, of BABO) have much more experience in this field, and have managed greater degrees of cure.

> As the correlation between the components of the eye is most often broken by

> any kind of eye exercise that your mind can muster (with or without
> stress-releaving lenses), pharmacological treatment (this option is for the
> future and should usually be coupled with the next to really qualify as
> cure), psychological treatment (to better understand the causes of myopia
> and possibly enhance "vision consciousness"), etc.

I don't think that there is any method of getting the eyeball to shorten after it has lengthened. My approach is to try and prevent things getting to the stage where anatomical changes take place. Regrettably this isn't always possible - sometimes patients come in already anatomically myopic; sometimes sometimes they don't follow advice; sometimes it seems that nothign works. I don't have all the answers (but I'm trying to increase my understanding of things).

IMHO There are 4 components to myopia:

1. Anatomical mis-match between refraction of cornea/lens and axial length of eye. This seems to result from prolonged abuse of the visual system - near centered work done to excess, often in less than ideal ergonomic conditions both physically and visually.
2. Excessive ciliary muscle activity (and/or inadequate ciliary relaxation) after near centred tasks. This seems to be how most myopes start off - transient distance blur.
3. Psycho-perceptual effects - it seems that myopes want to see everything "super-clear". Perhaps to some extent that's because eyecare professionals have conditioned them to this mode by the standard refraction examination technique, which majors on getting the best possible VA for distance, and not looking too closely at what the eyes are doing for close work.

4. Genetic pre-disposition. Myopic parents seem to have myopic kids. Now those against this debate might argue that the genetic component cannot (yet) be proven, and the cause might be environmental - children imitating their parents and concentrating on near centred tasks, perhaps also adopting an inappropriate posture, etc.. However, I think that the genetic pre-disposition component is valid, especially if a population base view is taken. According to various authorities (sorry - my way of saying that I've forgotten the reference!) the Inuit eskimoes (?Alaska) had a practically zero incidence of myopia until they were taught to read. The population with one of the longest histories of written civilisation, and using very complicated signs too - the Chinese - have become characterised as a myopic nation. I don't know whether any recent studies have been done which truly determine the real incidence of myopia in the orientals.

I think that of these four, numbers 2 and 4 go through 3 to result in 1.

Regards,

Richard

I couldn't agree more! The feeling of being at the mercy of the holiday season generates enough stress to last the whole year! We almost never get sick the years we stay home for the holidays. Our celebration at home is more seat-of-the-pants than major organizational event. We don't have a lot of "shoulds" or "have to's" - something I see a lot of when visiting relatives. I just returned from a visit, and yes, I have a cold! I had doors and windows open, but

George:

I and my wife have been taking bilberry faithfully for the past 8 or 9 months and are very favorably impressed with the results..I have been carefully watching for detrimental side effects and as of now have not detected any... Whether it would effect a pregnancy I don't have the least idea.. And at our age I really do not think we will find out..

About 4 or 5 months ago we recommended to a friend of ours back in Illinois who was having major eye problems after a stroke, that she try bilberry and be very careful if she detected any thing detrimental occuring that might be attributed to the bilberry..She started taking the berry and on her next appointment to an eye specialist in Springfield, Illinois she brought up the subject to get his opinion.

To both hers and my surprise, he said take it by all means. that there is some research on bilberry being done at t the University of Illinois and it was looking very good.

In our last conversation with her she is still having major eye problems and can't see that the berry has helped her a lot.

The thing I am curious about, is anyone aware of this research at the U of I and is there anyway we can find out about their findings

I mailed off my medical license renewal today. In the application it states, "New legislation requires physicians to provide patients with an informational brochure on breast cancer treatment options prior to providing treatment or performing a biopsy. A 32-page brochure has been developed by the California Department of Health Services and is available from the Medical Board of California free of charge." Information is given as to how to obtain this brochure.

I think similar informed consent should be required before people are treated with glasses or surgery. They should be informed that there is an alternative school of thought and research on alternatives. They should be informed that the World Health Organization considers myopia in children to be treatable with acupuncture (I recently read this, but not the studies on it which I am told are mostly in Chinese, any references would be appreciated).

I wrote to a consumer advocacy group about my concerns. They referred my concerns to an M.D. who does not think there are good alternative for myopia. If you have an opinion on this, personal experience, references, or papers, please write to:

Sidney M. Wolfe, M.D., Director
Public Citizen Health Research Group
2000 P. St. NW, Ste. 700
Washington, D.C., 20036

thanks
Julie Ralls, M.D.

Dear all,

Here's what I received from a subscriber of alt.folklore.herbs (she copied this out of "Rodale's Illustrated Encyclopedia of Herbs".)

"German experimentation suggested that 10 to 60 drops of the tincture could induce confusion of the mind and cephalalgia; violent pressure in the eyes with lacrimation, itch, redness, and swellings of the margins of the lids, dim vision, photophobia, weakness, sneezing, coryza, nausea, toothache, constipation, hoarseness, cough, expectoration, dyspnea, yawning, insomnia, polyuria (excessive urination), and diaphoresis."

Before you start worrying, however, consider that herbal tincture is a very potent preparation. Only a few drops are supposed to be taken at a time. What they put in capsules, on the other hand, is just powdered dry herbs. It's a mystery to me why those capsules are supposed to be effective. All traditional herbal medicines (Russian and Chinese, in particular) use herbs that are cooked or prepared in some way. I guess I'll have to ask on alt.folklore.herbs about it :-)

Obsessive myopia

- *Subject:* Obsessive myopia
 - *From:* stefansi@ctrvax.Vanderbilt.Edu (Stefan Stefanov)
 - *Date:* Thu, 18 Apr 1996 12:03:04 -0500
-

I was planning to write this months ago. Anyway, I now have a testimonial from another person to back it up, so this is also a good time.

After we outgrow the puberty stage when the eyes are more susceptible to refractive changes if abused, other factors that cause myopia increase in importance. These are primarily psychological factors but in my opinion, they still account, combined, for no more than 40% of the total. Close work is responsible for most of the rest.

Two and half years ago when I first got glasses with a cylindrical component I had severe headaches. These lasted not for 2-3 weeks as most optometrists would warn (my otherwise impeccable Zeiss optometrist also said so) but for 5-6 months. I did everything the power of my intellect came up with as a way out - rechecking prescription from various other sources, books, reduced and gradually increasing wear, etc. But let me tell you what really struck my mind as I was browsing through a book by some British MD from the 1970s. He wrote that some people with refractive problems get so obsessed by their condition that they blame everything on it and really make it almost a central point of their lives. Many of these people lack a clearly defined purpose in life so they latch onto their myopia subconsciously or not considering it almost as a source of meaning.

I have felt on a number of occasions this kind a feeling exuding from postings to I_SEE (mostly from females). While I wouldn't get into analysis of this now (for interested I would recommend the works of Nietzsche), I am pleased to post the answer of a PRK patient (a good 'net friend of mine) to a question I asked her yesterday on sci.med.vision (both follow). Note the underlying joie de vivre, the total engrossment in what one is doing. I only hope that her awakening to the potential dangers of close work does not cause her problems.

Hi Sue,

Once again let me congratulate you (this time also in public) on your
great PRK results. Comparing them to available distributions of outcomes
in your myopic range, you are on the lucky side.

Let me ask you a couple of questions: How much close work do you usually
do every day, and do you think close work has affected your vision
negatively during the last six months now that you see 20/25?

Best,

Stefan

Hi Stefan: So nice to hear from you again. It's so funny you asked me that question about "close work" affecting my eyes in a negative way... I was JUST thinking about that question myself earlier this morning.

I have totally taken my vision for granted. It's great, and I do everything and anything I want to do, and my eyes never fail me. On occasion people have asked "how I can spend so much time on the computer" without my eyes hurting or getting a headache. I have always just shrugged, never even occurred to me that it could be a problem.

I spend at least 8 hours a day staring at this monitor... sometimes more. And when I'm not doing this I am helping kids with homework, helping hubby with his paperwork, or reading. I never realized it before, but I guess I DO really push my eyes to the limit. But.... no problems.

I have been on the Net and chatting with people who would say "I have to get off of here before my eyes totally go nuts" and I can never relate to what they mean.

So I guess the answer is "no"... haven't noticed a negative thing about all the close work I do with my PRK eyes. <G> I was just wondering this morning if I am HURTING my eyes with all this close work, but I sincerely doubt it. I think I would be noticing some problems, if that were the case. Oh, and keep in mind, on top of all this close work, I only get about 3-4 hours of sleep per day. I have heard that alone is enough to bother some people's eyes. Yes, I guess I AM very lucky. Bye for now.... Sue

Julie;

I started optometry school two years ago specifically to go into vision therapy. It helped me and my daughter a lot and I was intrigued. So I worked part-time as a vision therapist for a couple of years before taking the big plunge to quit my nice secure government job and return to school at my advanced age!

I arrived in town and went to buy some car insurance from the agent right across the street from the school. She proceeded to tell me of her identical twin daughters (now in their twenties) who were both diagnosed with myopia when children at the school I attend. This school is one of the few optometry schools left that still believes in "functional" or "behavioral " optometry by the way. They prescribed both little girls minus lenses. As it turns out, one little girl dutifully wore her glasses and now years later is a moderate myope. Her twin sister refused to wear the glasses and guess what? I saw her in the office and she wears no lenses and sees fine (I have no specific data on her vision).

So that kind of shook me up. Why am I going to school anyway when people can just ignore all the stuff OD's recommend and do much BETTER!?

I still don't know, but have decided to stick this out, learn the traditional crap, and get my license. Then, I can hopefully look more into alternative methods of reducing/preventing myopia, binocular problems, visually-related learning problems, etc. By the way, I think occupational therapists have some good ideas on the mind/body connection that I will incorporate into my practice (if I can get through this stress-mill!). I enjoy your posts a lot by the way.

Has anyone bought whatever it is that Vision Freedom advertises? See extract below. Are they to be recommended? I'm interested but it sounds a bit commercial to me.

Thanks
Caroline

ANSWERS TO FREQUENTLY ASKED QUESTIONS ABOUT VISION FREEDOM

But you're not a doctor! Why should I believe YOU? History is full of new "breakthrough" technology from "outsiders" where the "professionals" have failed. Penicillin and airplanes, to name a few. The Wright brothers were bicycle mechanics!

Is this the age-old "Bates" method? No! Bates advocated relaxation....Vision Freedom is mechanical....(Exact opposites.)

If you have tried the "Bates" method to improve your vision, with or without any degree of success....You'll be pleasantly amazed.

Are they pinhole glasses? NO! Unlike pinhole glasses, when your VISION FREEDOM glasses are removed, your vision will be noticeably improved, WITHOUT your prescription glasses or contact lenses.

How does VISION FREEDOM work? Muscles control your vision. Your eye has muscles that adjust the focus (the image you see through it's lens) by physically changing your eyes' shape 35,000 to 100,000 times a day, much like an auto-focus camera. They are constantly changing the shape of your eyes to clearly focus on different objects to the best of your eye's current muscle strength and ability. Your lens' position changes as a result

of your eye muscles moving your eye back and forth, back and forth....

Your eye's ability to clearly focus on different objects is limited only by your eye muscles' strength. With VISION FREEDOM, you will exercise and strengthen your eye muscles as you read.. As a result, your vision WILL improve.

After my query about bilberry someone suggested getting them frozen from the supermarket. Are these likely to be the right sort? Although I haven't been and looked yet, I would expect that these will be a lot cheaper than any tablets, but I suppose that I may have to eat a lot to do any good.

Any views?

>What was the article about? Thanx, Eugene

The main thesis was/is that myopia is to a large extent an iatrogenic disease (i.e. caused by doctors) and can be prevented if corrective lenses are not prescribed/worn so zealously. The title of the thread stems from the fact that if the eye is NEVER corrected it cannot go beyond about 3.0 D which is the refractive error at which close work from about 33cm/13in would cause no accomodation. Higher refractive errors are due to the fact that a corrected eye is used again for close distance work whereby the myopic process is retriggered and perpetuated.

Regards,

Stefan Stefanov

Hi all,

This is the first time I've tried posting to a mailing list so lets hope it works. First some background about me. I am 22 years old, male and have been wearing glasses since I was ten (Twelve years count them). I got them soon after moving from Adelaide to Sydney and changing schools. My current level of Myopia is around -5.25 in both eyes according to the optometrist and I currently wear -3.75 lenses for both eyes with some correction for astigmatism.

Now my situation Last year I took off my glasses and stopped wearing them after reading Jane Goddard's Natural Vision Improvment abd Jacob Libermann's Take Off Your Glasses and See and I did notice some improvment but a lack of commitment (I wasn't palming or putting any real effort apart from not wearing my glasses anymore)and everyone saying don't be stupid you can't fix your eyes you'll just hurt them more. Began to wear me down. So When I moved house back into my parents house I put my glasses back on saying that I needed them to move, and I haven't taken them off again.

Anyway recently I broke up with my long term girlfriend and I have been blaming alot of things on my Myopia. Stuff like we broke up because of it. I'm too precise and picky because of it. I don't have a normal life because of it. I also found myself wondering what effect my break up would have on my vision ,it seems very up and down recently.

I would seem that I'm a victim off Obsessive Myopia. What are your thoughts?

Al

Ps. I would still like to improve my vision I just have make a stronger commitment again.

Hello ISEEers,

I just got back from my monthly visit to the optometrist.

The result: an improvement of 0.25 in both eyes.

So now I'm at L:-2.25, R:-2.75.

The optometrist said next month we'd be able to confirm that because it could be because I may have trained myself to read the blur!!! Well I don't think so but we'll see.

So folks, that was a good quick news update brought to you from DownUnder. Keep up your exercises, your balanced diet, your relaxation program and any other thing that you think is good for you and your eyes.

per Woo and Wilson , Current Methods of Treating and Preventing Myopia, A Review, Optometry and Vision Science, Vol. 67, no9 pp719-727- you can have both over and under correction with RK

>From Sher, Trobe and Weingeist- New Options for Vision Loss, Patient Care, September 15, 1995 re Laser-

-regression of more than 1.00 Diopters (this occurs in 12% of patients with myopia of up to -3.00D, 28% with -3.10 to -6.00, and 60% with more than -6.00 D)

-reduction in best corrected visual acuity of more than one Snellen's chart line in 3-4% of patients with myopia of -1.00 to -6.00D and a greater reduction in patients with more severe myopia.

p.62

I understand that there are some people in this user group who believe that vision and metaphysics have nothing in common. That is wonderful! I appreciate that you have the right to express your opinion and ask only that you allow me to expressing mine.

Can we not keep this valuable exchange of ideas free from any pressure to conform to any notion of what VT is or isn't?

When i make a posting expressing my views, i receive many personal comments from people (not always female!) who share my experiences. Generally they begin their letters by asking me to keep their correspondence private, as they feel uncomfortable going public for fear of derision. That is very unfortunate, don't you think? Are we not all looking for answers to the same problems? Do we have to pick sides? Does everything have to be a battleground?

Maybe someone out there has the answer we're all looking for but we haven't made it safe for them to speak up. We would all lose.

Two thousand years ago someone said how great it would be if we were all nice to each other for a change and they nailed him to a tree. Maybe we could try another approach.

Here's hoping.

I don't remember who said it, but i agree: <keep looking up!>

Linda, AKA (mostly female)

Vic,

I have myopia, astigmatism, and presbyopia. It seems to me that, if my vision were to improve, thanks to, say, eye exercises, all the way to normal vision, over a period of time, I'd have to get a whole series of new eyeglass prescriptions along the way to continue driving and using a computer. This could be a very expensive proposition. Any ideas? (If this is covered in the FAQ, I'm sorry, I missed it. Please just point me to it.)

Thank you,

George Victor

-

Here are some suggestions i have about keeping the cost of transition glasses to a minimum.

Personally, i shop second hand stores. My local one has a big bin of used glasses that i can surf through. I just look through the glasses and choose a pair that gives me blurrier vision than i now have. They cost a dollar a pair and so i can afford to make mistakes. Then i take them to the local glasses store and ask them to check the prescription. They are happy to do this if i take no more than five pairs in and come during slow times. If the glasses have a weird astigmatism correction then i'm out a buck and i don't use them.

My brother is particularly good at finding glasses that have no astigmatism correction. He holds the lense up to a light and looks through it at some lettering in the distance while rotating each lense individually. He says he can see a variation in the view if there is an astigmatism. I can't see what he sees, so i take him shopping with me. This is probably not practical for most of you since he lives on the west coast of Canada, but it works for me!

I have also found that it is possible to grind down lenses to a lower prescription, but probably within some limits. I once ordered a pair of glasses when i started VT and found that by the time they arrived,

one week later, my prescription was 1/2 a diopter weaker. The optician took the glasses back and ground them down to suit me.

Another thing you can do is to buy a pair of cheap reading glasses, ie plus glasses, and wear them over your regular glasses for close up work. This looks silly but it works. I have a pair of +1.5 that i wear at the computer when i have my 20/20 contacts or glasses on. You can also do this when you are reading close up.

And of course, the latest thing is 'computer glasses'. I stopped in at the local dispensing optician recently and told them i wanted a pair of reduced contact lenses for use at the computer and they gave me a pair for trial that were 1.5 diopter less then my normal myopic correction. That's the first time i ever prescribed my own lenses! If you are shy about asking your OD about 40/20 glasses, you could use the same ploy.

You can also check with friends to see if they have any old lenses kicking around. Invariably they will tell you that they have no idea what prescription they are, but that they are 'blind as a bat' without them. Check them out with the optician and use them if they work.

(aside) It always amazes me that people can effortlessly recite complicated pharmaceutical or nutritional prescriptions they are taking but are completely ignorant about what's happening right in front of their eyes. (end aside)

I understand that you are wearing bi-focal lenses, and so none of these hints might help you. Perhaps you can get into a habit of switching glasses to suit your viewing needs, ie, minus lenses for far away and plus lenses for close up. I understand that common VT wisdom is to ignore astigmatism corrections in transition glasses.

. . . and i think that is everything i know about cheap transition glasses . . .

Linda

This is generally true, but one way to cut down on costs is to reuse your frames, and to avoid all the "extras" (eg. coatings - is scratch resistance so important if you're going to get new lenses in a few months?).

If you do this, new lenses should be in the US\$50-65 area (unless they're bifocals, in which case they'd be more), not too bad when you consider the benefits accrued from VT (eg. say you're -5.00 and you get new lenses every 1.00 shift; that's 3 or 4 sets [at the -1.00 level you're around 20/40, which is legal for driving everywhere I've been and fine for computer work, so you may not want lenses at all] for about \$200, plus you've probably got a couple of frames from old glasses). So is clear vision without glasses worth \$200?

>I understand that there are some people in this user group who
>believe that vision and metaphysics have nothing in common. That is
>wonderful!

Linda,

I appreciate this post of yours. I notice it has been implicitly directed to me so I'd take the time to respond.

You'll be surprised to know how metaphysical I am. You have probably never met someone as metaphysical. The most important thing is that we cannot be qualified as belonging to a certain school of thought. The reason for this is that any qualification is off something while we are off NOTHING. With this stipulation I can align myself to the neo hinduism or philosophical linguistics (some names in the field: Derrida, Ricoeur, Lacan, Levinas, Owens, Valerie). We regard matter as a frozen thought, therefore we are something like Idealistic monists. Matter or energy (these are equivalent - see Einstein) are a fallout of the Asymmetric Tendency in the universe whereby Thought cannot sustain its purity and in attempt to get to Know itself gives birth to matter (the me vs the other antinomy in French existentialism). The wickedness manifests itself through Thought not finding itself self-sufficient. To cut it short, I am presently working into unifying the purely Idealistic paradigms (Kant, Hegel, Heidegger, Kierkegaard, Sartre) with Utilitarian paradigms. Beyond Beauty and Uninterestedness I observe the utilitarian aspect in, for example, bees visiting flowers, or the firs having needles.

The guilt that you touched upon in one of your previous postings we regard as petty humanistic. The Guilt we mean is the Unsustainability of the Symmetry (or the Difference). A material equivalent in nuclear physics is

the discovery that none of the three basic symmetries held. However, it is in quantum physics where materialists and we, idealists, tend to converge - the "laws" in quantum physics most closely resemble esthetics principles and music.

>I appreciate that you have the right to express your
>opinion and ask only that you allow me to expressing mine.

I have never forbidden you to express your opinion. Post as much as you want. The power to let you through rests with Alex.

>Can we not keep this valuable exchange of ideas free from any
>pressure to conform to any notion of what VT is or isn't?

If a post conveys an idea it asserts something. This should not be thought of as pressure by independent minds. Any idea can be supported or challenged by others. The history of the world is one of the rise and fall of ideas.

>When i make a posting expressing my views, i receive many personal
>comments from people (not always female!) who share my experiences.
>Generally they begin their letters by asking me to keep their
>correspondence private, as they feel uncomfortable going public for
>fear of derision. That is very unfortunate, don't you think? Are
>we not all looking for answers to the same problems? Do we have to
>pick sides? Does everything have to be a battleground?

The "battleground" is a result of the Difference. I join you in extending an invitation to all who have not spoken publicly so far to do so. These people may possess valuable and enlightening ideas for the benefit of all. As to picking sides, there is a point in development after which All people are the same. Until then the Difference rules.

I enjoy a great self-confidence because I feel the pulse of the Universe (anyone can claim this, of course). I have never seen anyone more self-confident than me. But I have seen many people as self-confident as me. Recent examples are Richard Fuld, Chief Executive Officer of Lehman Brothers Holding, Inc. (a top-five Wall Street investment bank) whom I met this Friday, and the former British Prime Minister Baroness Margaret Thatcher whom I had the honor of meeting Wednesday. I believe we have reached the "Sameness level".

The above is the reason why we welcome confusion as a most valuable experience. After each confusion we emerge stronger. I shall only be too grateful to those who point to where I wrong. Furthermore, I beg you to. Companies pay millions to consultants to tell them what they do wrong. Of course, I have the right to respond critically. But I am not pompously proud not to change my mind. It is through total humbleness and loss of the self that we reach Unity.

>Maybe someone out there has the answer we're all looking for but we
>haven't made it safe for them to speak up. We would all lose.

Please come forward. The enlightened have no fear.

>Two thousand years ago someone said how great it would be if we were
>all nice to each other for a change and they nailed him to a tree.
>Maybe we could try another approach.

I think he was naive. God died in the Church. To the masses, Religion is
Philosophy. To the few, Philosophy is Religion.

>

>Linda, AKA (mostly female)

I admit, I may have hurt the fair sex. Please, pardon me, I meant nothing
sexist. It's probably the too many statistical studies that I read. There,
the two most common predictors are gender and age. Since I don't know the
age of posters, I tried to "predict" by gender. From now on I shall try to
abstain from making this distinction when not quoting statistical studies.

Best regards,

Stefan Stefanov

I tried to answer some of the questions, but when I tried to send those answers out, my computer disconnected from AOL. S I'll try sending several short messages. For some reason, that has worked in the past when a piece of mail won't go through.

1. Why do objects become clear?

I think this is better explained with diagrams. Check out an ophthalmology text or a basic camera book. It has to do with how the light is bent as it enters the eye and where the bent rays meet in the back of the eye. If you really want detail, I can try and write it out but it takes a while and in this case a picture is worth a thousand words.

Some of these answers are from a technical side, some from a practical patient view side

2. glasses vs contacts

For me glasses were more comfortable for my eyeballs, but less for my face. I developed dry eyes in medical school and had a horrible time trying to get contacts that didn't start burning and irritating my eyes after a few hours. I'd be asked if I had conjunctivitis because they would get blood shot. With the glasses I didn't need any of those cleaning solutions, the mess and bother, like a makeup kit. Contacts were more expensive.

The glasses are a pain though too. You look like a geek. You do your eye make-perfect then cover it all up with those lenses. The glasses don't strap around your face so you always have this annoying foreign object in the periphery of your vision. Kids call you four-eyes. You get picked last for field games. None of the boys will kiss you. Even if they would, you think they won't. you can never be a cheerleader. You don't smile as much. It is really awkward to try and relax with your boyfriend in front of the TV and makeout while watching TV. (And I had such dry eyes that I couldn't wear the contacts in the evening, they hurt too much. So I'd switch to the glasses by dinner time, just when I needed to be the most sexy and elegant.) You have to take the glasses off to kiss him then put them back on to see the movie.

On, off, on, off. It spoils the mood. When people hug you, your frames get bent. etc.

3. I got contact lenses in grade school, hard. This was before soft lenses were introduced. There were some studies showing hard lenses might slow the progression of myopia. My doctor also wanted me to be beautiful and I did look better without the glasses, and I felt better about how I looked. Then soft lenses came in. They were much more comfortable. I think the gas permeable lenses are healthier for the cornea. More oxygen can get to the surface of the eye (at least that is what I remember being told). With my dry eyes, I was given soft lenses with the highest water content. Those seem to feel the best and cause the least redness and irritation. I ended up using extended wear lenses but taking them out each night and tossing them after 2 weeks. The extended wear users had higher rates of corneal ulceration. All my doctors recommended against my using contacts overnight with my dry eyes. The risk of ulceration and infection was too high. I dreamed of the day I would get laser surgery and wake up in the morning and see the clock clearly. Now I wouldn't touch the surgery because I think the non-surgical alternatives are better.

4. Laser sort of evaporates cells. It breaks molecular bonds without damaging adjacent tissues. With it you can reshape the cornea and change its curvature. Thus you change how much the light bends as it enters the eye. You might want to look at a physics book, the section on optics to learn about this. I need to review it myself. It has been a while. There is minimal damage to the cornea. I've now had several friends get this and they see 20/20 and love the results. I think it's a horrible idea compared to vision therapy.

RK cuts the eye. There is more scarring with RK. The doctor makes several radial incisions around the cornea. This causes the cornea to flatten a little. Again, a diagram would be good here. RK is less precise than the laser.

 - *Sender:* owner-i_see@indiana.edu
-

5. Side effects- per Woo and Wilson, Current Methods of Treating and Preventing Myopia, A Review, Optometry and Vision Science, Vol, 67, no 9 pp 719-727 For RK- "Under correction or over-correction, increased glare sensitivity, photophobia, monocular diplopia, fluctuation of vision, increased or irregular astigmatism, regression of the refractive change, and early onset of presbyopia. Also recurrent corneal erosions, iritis, microbial keratitis, corneal perforations, hyphema, cataract, endophthalmitis, intrastromal abscess, corneal iron lines, limbal vascularization and epithelial implantation cysts. Complete loss of vision can follow large perforations of the anterior capsule of the lens, infection of the corneal incisions, and in eyes with abnormal corneas." p 720. Now take a look at a PDR. The percentages of these side effects are very small, but a patient should be aware of the risks. In the PDR you can look up thousands of drugs and their side effects. The lists of side effects look horrible and you would think no one should ever be taking such dangerous drugs. But you have to compare risk versus benefit. Few people get severe side effects and many people can benefit from medication.

-

5. Side effects- From Sher, Trobe, Weingeist- New Options for Vision Loss, Patient Care, September 15, 1995. Laser- bacterial infection- 0.1 % corneal hazing in the healing process which usually fades. Severe, permanent haze that may interfere with vision occurs in fewer than 1% of patients. Most ophthalmologists believe that it is safer than using extended-wear contact lenses.

-regression of more than 1.00 diopters(this occurs in 12% of patients with myopia of up to -3.00 D, 28% with -3.10 D to -6.00 D, and 60% with more than -6.00 D)

- reduction in best corrected visual acuity of more than one Snellen's chart line in 3-4% of patients with myopia of -1.00 to -6.00 D and a greater reduction in patients with more severe myopia.

-a halo around lights sufficient to impair night driving in 12%

p 62

I found it interesting that this Dr. Sher has the same name as a Dr. Sher who coauthored another article on the Laser in Arch Ophthalmology, vol 109, nov 1991. That is a specialty journal. In that journal the reader is notified that Dr. Sher at one time had investments in the company that developed the laser. Also that company, VISX, helped fund the research. So the reader should be aware that an economic bias might exist. Science doesn't happen in a vacuum. (this would be a whole nother research paper) . But Patient Care, which is for primary care physicians like myself, does not mention that connection. The Patient Care article explains the surgery very well and the diagrams are good too.

7. Can myopia.... Yes- I don't have specific references but according to a local doctor of Oriental Medicine, myopia in children can be treated with acupuncture. This is the position of the World Health Organization according to Dr. Tung of Corona del Mar, California. This is't natural but it is non-surgical. Also there are acupressure points that can be used to improve vision. You can use biofeedback, reading glasses, visual hygiene measures, exercises, the Bates method. Here' s some references:

-Sherman, Arnold, O.D., Myopia Can Often be Prevented, Controlled or Eliminated, Journal of Behavioral Optometry, Vol. 4, No 1 p16, 1993. (This is my personal favorite)

Leber, Leray, PhD., Wilson, Thomas, O.D., Myopia Reduction Training- With A Computer Based Behavioral Technique, A Preliminary Report, Journal of Behavioral Optometry, Vol 4, No 4, p 87, 1993.

Orfield, Antonia, MA, OD Seeing Space, Undergoing Brain Re-Programming to Reduce Myopia, Journal of Behavioral Optometry, Vol5, No 5, p123, 1994

Trachtmen, Joseph N. Biofeedback of Accommodation to Reduce Myopia: A Review, American Journal of Optometry and Physiological Optics, Vol. 64, No 8, pp 639-643. 1987.

Grosvenor, Theodore, OD PhD, The Results of Myopia Control Studies Have Not Been Encouraging, Journal of Behavioral Optometry, Vol 4, No 1, p 17, 1993.

Gottlieb, Raymond, "Neuropsychology of Myopia" Journal of Optometric Vision Development, Vol 13, no 1 March 1982, pp 3-27- This article nicely outlines

the different theories on the etiology of myopia.

My solution to transition glasses costs no more than I was already spending - I have been using disposable lenses for the last 4 years. The trick is to gradually reduce the prescription as my vision improves :)

Since my right and left eye are near the same, and lenses come in six-packs, I have anywhere from three to six (maybe nine) weeks to decide if I want to reduce again.

I also have glasses, with no correction for astigmatism, that are even weaker than the contact lenses. Some days I go with out any correction, when I am at home and doing un(visually)demanding chores. I cleared and mulched the flower beds quite nicely without lenses, and enjoyed it greatly. I am finding that many things I can do without lenses are more satisfying than the things I must have lenses for. Jumping on the kids' trampoline, eating, playing ball with the kids, juggling, napping, and though it scares Elena, driving in familiar places with our bright Florida sunshine.

Thanks for the tips on low cost lens reduction.

Can a correction for astigmatism be ground out?
In other words, I could get a lower prescription, then have my existing lenses ground re-ground. However, I look forward to eliminating my astigmatism correction eventually. It has never remained the same over the years anyway and has most likely already changed. Can it be ground out? (I don't know much about lenses except for the usual concave/convex stuff with a smattering of focal point trivia.)

You are referring to an effective field method to test for cylindrical component in the spectacle lens. I believe anyone can learn to use it.

To put it simply, since the existence of a cylinder makes the refractive power different in every meridian, by gradually rotating the lens while looking through it with one eye you should be able to see changes/distortions in the image. You have to hold the glasses pretty stable and keep the distance between them and the viewing eye the same.

Trying this with my former 20/20 glasses which have some negative cylinder at approximately zero degrees I actually notice that letters get compressed horizontally, i.e. they get thinner (at 0 deg) and normal, i.e. fatter (at 90 deg).

The trick is to learn to distinguish between changes due to minification/magnification caused by a possible shift in the viewing distance (it's not easy to hold the glasses at perfectly the same distance while rotating them) and more "weird" changes as described above.

Regards,

Stefan Stefanov

Isn't driving great without glasses!!! It gives a good dose of confidence that my vision is getting better.

BTW, what's your 20/20 prescription?

george

Subject: Re: Transition Glasses

My solution to transition glasses costs no more than I was already spending - I have been using disposable lenses for the last 4 years. The trick is to gradually reduce the prescription as my vision improves :)

Since my right and left eye are near the same, and lenses come in six-packs, I have anywhere from three to six (maybe nine) weeks to decide if I want to reduce again.

I also have glasses, with no correction for astigmatism, that are even weaker than the contact lenses. Some days I go with out any correction, when I am at home and doing un(visually)demanding chores. I cleared and mulched the flower beds quite nicely without lenses, and enjoyed it greatly. I am finding that many things I can do without lenses are more satisfying than the things I must have lenses for. Jumping on the kids' trampoline, eating, playing ball with the kids, juggling, napping, and though it scares Elena, driving in familiar places with our bright Florida sunshine.

These were my numbers

R -5.50 -75 axis 175

L -5.75 -75 axis 5

back in January 1996. I haven't been checked since then, so that is the most accurate I have. I personally notice a shift in accuity between my two eyes. Sometimes they are the same, sometimes one or the other is a little clearer.

Just came back from my local O.D. I decided to see what my power would be for nearsightedness. Here's what happened:

First the lady took me to this dark room, showed some small letters, for 2 secs, then did that to the other eye, when that was over, i believe she did a glaucoma test. She told me to wait for the doctor.

I waited for about 20mins, and then the doctor called, he asked me whats my visual problem is, etc. Then he made me sit in this chair, and showed some letters, they were so blurry, I couldnt see any of them!!. Anyway he started flippinf the lenses, and asking better or worse, I honestly answered. Then he did a convergeance test, by moving the pencil in different directions. Then he started to "squeezing the letters," and asking me if its better or not. Astigmatism test? Then he showed me a tic-tac-toe board, and asked me which lines (horizontal, or vertical) looked sharper, I kept saying the horizontal ones, since they seemed blacker, he concluded the exam, by writing me the prescription, and asking me to and pick glasses, I refused, and just took the prescription and left.

My prescription is:

OD -1.50 sph.
OS -1.25 sph.

Obviously no astigmatism.

Now I have something to compare to, as my vision improves! ;)

have an eyes day,
Eugene

When I first wanted to get the 20/40 lenses I called a couple of places because I didn't want to take off work to see the doctor just for this. I wanted to go somewhere like lens crafters and just get the lenses and try the idea out. They didn't know what I was talking about. They weren't familiar with the concept. I had to argue a little about it. I'd ask- what would it hurt, even if it doesn't help? Finally I called my doctor and we discussed it. He'd be willing to give it a shot but I'd have to come in- and I was paying this guy cash for services for the last few years. When I had first called, I told the receptionist what I wanted to do. She goes, "Oh, that's the old school!" I'm thinking, old school? What old school? You guys knew about this all along and never told me!. I had a chance to try this in second grade but nobody bothered to inform me of this possibility? M____r F____s!!!!!!!!!!!!!! If this works, I'm going to strangle you all, non-violently of course .It turned there was a women's sailing conference starting at 8:30, and my eye appointment was at 9. So I just whited out my old prescription, dropped each side by 0.5 diopters, xeroxed it and got another set of glasses on my own and cancelled the appointment. I really don't need a doctor when I have white out.

I think it will be funny historically that a Dr. discounted Bates. I've just skimmed his books. He saw example after example of phenomenon that made it clear to him that the established paradigm was wrong. Myopia and astigmatism spontaneously reversing. It's not supposed to do that.

I was told I had long eyes. They grew too long. It was genetic. Now I've been asking people about their vision history for over a year now. How are all these adults growing long eyes? So many adults with a new onset of myopia. Several friends and my oldest brother were prescribed lenses but didn't wear them. Now they see fine. I wore mine. What a goof! Bates' method does see a bit kooky but at least he was doing less harm than those that ridiculed him.

Hi

I'm fairly new to all of this and my eyes aren't very bad (-0.5 and -1), but I'd like to try to correct them naturally.

I've read lots of what you've all been saying and I have been out and got some +3.0 glasses (they seemed about right for reading).

I've worked out already that I misjudge distances with them (I fell 'up' the stairs yesterday when I didn't take them off after having tried them!), but assuming I stick strictly to reading and not moving around in the future, can someone reassure me that there is nothing I can do to harm my eyes in this way? I just wondered, because if I do bring something close enough to be unblurred (for a moment), it is much bigger than it should be.

I suppose I could always ask an optician but I don't trust their opinions anymore!

Thanks

Caroline Richards

Sure looks to me like it's the close up work with the negative diopter lenses that will harm your eyes, not the other way around. The positive lenses should protect your eyes. Myopes get more glaucoma, retinal detachment, vitreous degeneration. I don't know the mechanism but it related to lots of close up work.

My primary reason to go there was to get my diopters, thats it, and to check the health of my eye. He told me he would give me not full strength glaasses. SO evidently he wouldnt treat it.

I fully 110% agree, maybe genetic myopia accounts for 5% of the cases, but mostly its close work. I currently wear +1 for pc , and +2 for reading.

Hi there just thought I would let everyone know about my last visit to the opticians. To bring everyone up to date. I started VT right about the 26th of december 1995 my starting prescription was

-5.50 R
-5.75 .25 180 L

one month later jan.1996 I had my first eye exam with rather exciting results.

-4.75R
-4.75L still a slight astigmatism

I was fitted with some T glasses at -3.50 each eye no correction for the astigmatism.

I went back for another exam a couple of days ago and my latest results are

-4.25 each eye no astigmatism

I could read the 20/15 line with my right eye with this prescription so I would say my right eye is slightly stronger.
Kept the same T glasses.

I find walking outdoors to be the greatest thing to do. It gives me the greatest pleasure. My clear flashes some days seem to last the whole walk. Reading the newspaper is so much easier now. But this computer is still a drag I can't last very long in front of it.

update

good luck one and all
alexandra

Well this might take a while. The first month I practically palmed the whole time. I barely left my apartment. I also tried every exercise. I read all the books I could find. I got a full spectrum light and sunned with that or stood outside and sunned every day. I take eyebright tea twice a day. (less than that lately.) The brand of tea is crystal star it is a blend. I took a slew of vitamins now I just take vital eyes by source naturals it is pretty much everything I was taking in one pill. I also take pycnogenol by the same company. They are pretty pricey but I just decided to dive right in and try everything I could.

I think there has been a couple of turning points one being relearning how to blink. I can't stress enough how important this was. Originally my blinks were very sticky. I literally sat in a chair and blinked for about an hour. Now my blinks are natual and effortless. I used to have to tell myself to blink now I take it for granted.

When I started VT I went cold turkey used no glasses for about a week then found and old pair. Found out later the old pair was -4.50 each with a correction on the left for an astigmatism.

I could go on forever describing everything I have been through emotionally and otherwise but I will try and refrain and just let you know what routine I have.

Wake up stretch my eyes. First I blink hard squeeze my eyes shut then open them wide a few times. Look up count to five, look down count to five, look up down rapidly ten times. do the same for left to right. then circle your eyes slowly stopping at all the numbers on a imaginary clock face, first clockways then counterclockways. Remember to breathe, this is a yoga exercise. Then I visualize energy in the back of my head going through to my retina blink three times look up then down, left right left, right, to the third eye then straight out. Then palm for about ten minutes. Also I blink very rapidly many times. All this is done before I get out of bed. Oh also I sometimes do accupressure which I do several times a day. I think they are described in Libermans book. Massage my shoulders and sometimes my face.

Get up take vitamins and eyebright tea.

If I am really being good I do standing meditation and some tai chi. Standing meditaion was one of the things that got me started on VT. I would be meditating and my left eye would tear a lot it was as if it was trying to balance out which it did. It still tears from time to time less intensely then before. I don't know what it means but it made me think more about the regenerative properties of the eyes. Two exercises in particular neck circles and the universal stance. Both of these work your eyes.

One very important thing I try to do every day is to take a long walk. Which is so great. Can't recommend it enough.

Also I do Dr. Kaplan's swing ball a couple of times a day. Thank you Dr. Kaplan :)

If I'm being really good I throw on a cd and palm for about a half hour or more.

My shoulders really were a killer in the beginning. They needed alot of self massage. I also sometimes wash out my eyes sometimes with eyebright tea sometimes just plain water.

I use to do alot of swinging and yawning but don't lately.

Well that is enough. I probably left some stuff out.

Good luck with your efforts. and thanks for the reply
alexandra

If you have just started Visual Therapy as a cure for myopia and are finding that it doesn't seem to be working, don't give up.

The optical trade may say there's nothing in it, but if you follow the Usenet group sci.med.vision, you will see that they are unable to quote any studies disproving it. Many people have asked in that forum for references to such studies, but are always met with either a deafening silence or a change of subject or simple abuse.

I cannot offer you any objective proof that it works, but here's my story so far. Its nowhere near as good as others (especially Elena's :-)) but I'm becoming more of an optimist every day and my experiences have certainly convinced me.

My Background

=====

51 year old, been myopic for 40ish years, the first 20 with glasses and contact lenses the last 20 with glasses only. I use a computer for most of the day. I've had a gradual increase in myopia over the years with my latest prescription 18 months ago :-

L -4.25 Prism 1 deg

R -3.75 Prism 2 deg

Both with a small amount of astigmatism.

I started having doubts about the optical trade three years ago when I went to see if it was possible to remove the need for prisms by eye exercises. The vehement denial that anything could be done made me

feel uneasy at the time - I wondered why he should be so cross. Some time later, a colleague told me that he had reversed his trend towards presbyopia by using the Bates Method. After my experience over the prisms, I thought "why not give it a try - it cannot do any harm"

I started seriously at the end of October last year, and within a week had received a great benefit. There was no change at all in my visual acuity, but the change in my 3-D awareness meant that I could go walking on the nearby hills in drizzle and mist without my glasses - normally they steam over and I can't see anything. This may not seem that exciting, but it brought with it an awareness that much of vision is to do with the mind.

I struggled on for the next 4 months with no more progress, other than realising how much my eyesight varied. How could it? - according to the men in white coats the eyeball is solid. What kept me going was knowing personally someone who had had success and hearing over the Net of those who had made substantial progress.

Then - magic - although for some time, some objects had shimmered when I looked at them in a certain way, this had not been accompanied by any improvement in acuity. However, while washing up the dishes, I suddenly became aware that I could see the garden plants with a vastly improved clarity. This was proof to me that the standard theory that myopia had no cure was wrong and was a marvellous experience.

Shortly after this I had a second superb experience. I suddenly found, with no effort at all and my eyes feeling completely relaxed, that I could make out the features of someone about 150 feet away. This was amazing, as my rough calculations make it close to the theoretical best resolution of 1 minute of arc. I've not been able to reproduce this since, but the memory will stay with me for a long time and shows me that even after 40 years of misuse my equipment is still in working order.

The third encouraging event was standing 42 paces from a car and being able to read the number plate for about twenty seconds. My normal distance without glasses is 3 to 4 paces.

This happened about six weeks ago and my day-to-day eyesight has not improved. Surprisingly, this doesn't worry me, as I still have frequent "clear flashes" and feel pretty sure that it will come good in time.

My current blocks are

- a) The inability to get relaxation from palming, although I do see black for the first ten seconds of palming after sunning.
b) Not being able to visualise with my eyes shut.
Any suggestions in these areas gratefully received.

Peter

I'd like to install some new fluorescent lighting in my home. General Electric manufactures some tubes which it calls "Natural Color". Does anyone know if these tubes are 'full spectrum', or do they only reproduce the visual spectrum of sunlight?

Peter,

there are a number of factors that would affect what you 'see' during palming:

(I'm assuming that you are fully covering your eyes so that no external light can filter through to your eyelids)

- 1- the state of your mind: people can't relax 100% (only dead people can do it) so it is quite normal to have some mental images popping up as long as they do not cause any physical tension which brings me to the next point...
- 2- If the eyelids are shut tight putting some pressure on the cornea, or if the hands are pushing against it, then you may experience some light patches
- 3- sometimes after using the eyes for an extended period of time I find that when close my eyes (without exerting any muscular tension to do that) the eyelids sort of vibrate and at the same time some tiny lights appear.

Having said all that make sure that you're not looking for darkness when palming otherwise you may see the Mother Ship crossing the Milky Way.

I agree with you, it's 10% physical and 90% mental.

Now, palming after sunning produces a light darkness which I think is caused by some hyperactivity in the retina due to its exposure to intense light.

Edging is a mental process that doesn't have anything to do with vision (of course you have to see the thing first). being able to visualise things is something that you can learn and has a positive impact on your memory skills. Contrary to what people think, we all have photographic memory. otherwise we wouldn't be able to recognise our family, the houses we live in...

Start with something simple like a letter on the eye chart, break it down into pieces.... I also found that since I started VT about 4 months ago, my visual memory became much better probably because I now pay more attention to what I'm looking at especially faces (which was a major problem for me because I meet a lot of people and I feel bad when I don't recognise them)

hope this helps

george

> >My current blocks are

> >a) The inability to get relaxation from palming, although I do see
> >black for the first ten seconds of palming after sunning.

>

> What do you see after the initial 10 seconds? it should be pretty dark with
> the eyes covered.

Difficult to describe, but not jet black. A bit like the Milky Way with even more stars, but each one is not very bright. There are also lighter areas, which increase in number as my eye-strain increases. Its also interesting that the more frustrated I get with not getting relief, the worse it gets. I started off in this game thinking that the solution was going to be purely physical and that "exercises" were all you need to do. Now I'm beginning to feel that the "exercises" are there just to help the mind do what it should be doing all along. i.e. following the Alexander Technique idea of not doing the wrong thing, rather than trying too hard to do the correct thing. What do you find most successful?

> What happens if you palm without sunning first?

Straight into the Milky Way.

> >b) Not being able to visualise with my eyes shut.

>

> What are you trying to visualise? are you trying to draw an object or word
> sort of like edging it?

Just trying to remember any object. Either from something I've just seen or dragging it out of memory. I haven't been able to draw or edge at all.

> Can you visualise other 'things' (events, trips, walk...)? how about the face

> of someone? you should be able to do that.

Very fleetingly and very faintly. I've found it interesting that several other people I've asked can not see anything - even though they've got good eyesight, although they can all see black when palming.

Thanks again for the interest and keep up the good work.

Peter

Vision fitness lenses

- To: i_see@indiana.edu
 - Subject: Vision fitness lenses
 - From: carlwils@cln.etc.bc.ca (carla wilson)
 - Date: Tue, 7 May 1996 16:28:39 -0700
 - Sender: owner-i_see@indiana.edu
-

I have a question which I am sure has already been discussed. It's about vision fitness lenses. I am ordering some new contact lenses and rather than ordering the full strength perscription that the optometrist has given me, I'd like to ask her to order a reduced perscription. How much is a reduced perscription usually reduced by? .25, .50? With this reduced perscription, will it still be safe for me to drive? When ordering new lenses for glasses, is it usually reduced by the same amount? If not, how much?

Thanks for the help,
Carla

I reduced mine by .25 (-4.00 from -4.25). However, that might not seem like enough, so get them to give you a sample pair of disposables (all the manufacturers give them out). It has worked for me. I wear plus lenses (+1.75) on top of my contacts when ever I read or us the computer - really makes a difference. The next box I get will be -3.75's.

Hi Alistair

I decided to include the whole group in my reply because someone else may have some comments to help either of us.

I'm really not sure whether you should go cold turkey or not. How bad are your eyes? It's ok for me to do that because mine are -0.5 and -1.0, which just means I can't read bus numbers/signposts from far away. Perhaps it should be a decision you take based on your likelihood to continue if you put yourself off too soon! How about getting some weaker glasses? (I guess that leads to extra expense unless you use contact lenses but at least then you would be doing your eyes some good all the time whilst not being too uncomfortable in yourself).

To be quite honest, I was disappointed with Tony (Sydney 607 2125) but I'm confused as to how much of it was personal and how much of it was because I think he could have done things better. I'm supposed to go back for a second day but I don't think I shall. I didn't feel comfortable with him and I didn't like the setting (his home with his wife around half the time). I felt in the way and it didn't feel very professional.

When I asked him questions he talked round the subject a lot, but I didn't always get a straight answer. He spent a lot of time on the reasons why your eyes could be bad and in improving those reasons, but he didn't test my eyes or try to see if my sight was better.

He based most of his analysis of me and my state from muscle testing. I

forget the name; it begins with K (kineisiology??? Something like that).

It's often used to test food allergies. The trouble was, I felt it was a bit subjective. Here's how it goes:

You hold out your arm horizontally and to the side and he presses down on it. You try to resist it being pushed downwards. This is the 'standard'. Then he does something like touch you on a certain spot on your shoulder or show you a picture that will indicate how left brain-dominated you are or make you hold/think about a particular food or whatever. Then he tests again and says whether you were affected by what had happened. If you are and you can no longer resist his pressure, your general 'balance' is bad and your eyesight should be stressed. If you aren't, then that situation is ok for you.

The trouble is, he says he presses with the same pressure each time but it feels all very subjective to me. I reckoned I could influence the results if I tried. I never felt stronger or weaker after what he'd just done; it felt more as if he pressed harder or less hard, although he assured me that he had been measured and was consistent.

Perhaps I'm just a sceptic but I'd rather have had a test that measured something objectively..

He did go over the routine Bates stuff, like palming and sunning. He also showed me how he splashes his closed eyes with water and then puts his face in hot and then cold water to refresh his eyes. He showed me how he does his eye exercises whilst doing a mild workout on a trampoline, which he says is good for lymphatic drainage. He ended up with some meditation to get rid of the natural stress that he says light often causes due to a traumatic birth from a safe dark place into a harsh brightly lit world.

He says that there can be 4 major causes of eyesight problems and he uses muscle testing to see which is the most likely cause in your case. He said mine was mostly emotional, as opposed to due to food intake, purely physical or whatever the fourth one was. He went further and said that something happened to me on 18th November, 1976 and that it influenced my eyesight.

(I can't think of anything specifically but my family had split up and it's quite possible that something happened that day.)

Quite a mixture, but in each case he 'proved' that what we had just done had done my eyes good by means of the muscle test, which didn't convince me!

I've rambled on at you quite enough now. For the moment my only dedicated eye care is avoiding my lenses (no big deal for me, as I explained) and making sure that I sit as far away from my computer screen/television//book as I can whilst still seeing well enough not to get irritable! At work I have a scheduler reminder that prompts me every 20 minutes to look up for a while and focus on something distant.

I'm happy that these actions will stop my eyes getting worse, but I don't have much faith in them improving. I can't seem to make a time for palming for more than about 30 seconds. I find it very uncomfortable unless I can lean forwards on my arms and at work people will think I'm asleep! I'm contemplating sunning but am worried about getting wrinkley skin around my eyes! I occasionally use an eye patch at home as a substitute for palming.

If someone could really convince me that it would do some good I'd be happy to use one all the time whilst watching television. or reading.

That's all for now, sorry it isn't better news. Perhaps someone else will jump in with something to correct my gloomy outlook!

Caroline

Hi there Caroline,

How was the thing with Tony? Do you think it would be worth going to for me if I had to come up to Sydney. (how can I get in contact with him - he might want to run a course down in Canberra). I have started to go without my glasses again but I am just starting slowly and not wearing them until I leave home. Next I'll leave them off when I ride my bike to Uni then I leave them off all the time unless I'm in a lecture or looking for someone or climbing. What do you think? or should I just go cold turkey. I find the hardest part not putting them on Straight away when I get up. Then I'll have to introduce palming and sunning into my daily routine.

Regards

Alistair

The following is just my personal opinion based on what Caroline stated in her e-mail note. If there are those that have been helped by either muscle-testing or Tony Paul Gaynor, then perhaps it's all a matter of the compatibility of personal styles. I was motivated to say something because I have had a tiny bit of experience with alternative methods of healing.

Mark

From: Mark Jones <mjones@hp7201>

Caroline,

I read your report on your visit to Tony Paul Gaynor with great interest. My first thought was to trust your feelings and avoid him like the plague. He does not stike me as someone who can listen, see, feel, and self-lessly help someone. I have seen muscle-testing for allergies and it can be influenced by a practitioner who is him- or her-self unbalanced (IMHO).

>confused as to how much of it was personal and how much of it was because I
>think he could have done things better.

Don't worry about it. It sounds like your intuition was perceiving signs that he was a bit off in his application of his model.

It sounds like he is overly attached to his model.

>He ended up with some meditation to get rid
>of the natural stress that he says light often causes due to a traumatic
>birth from a safe dark place into a harsh brightly lit world.

This is a good indicator of an unbalanced wacko. Birth and light are inevitable. To make birth the focus of one's dissatisfaction with life can be a self-pitying cop-out. I have known a few people for whom birth from the dark into the oh so cold and harsh bright world was an issue. I did not feel compatible with them.

>He says that there can be 4 major causes of eyesight problems and he uses

Well, there are a number of factors that can influence eyesight. Robert Kaplan's book is very good in exploring some of those different factors.

>Quite a mixture, but in each case he 'proved' that what we had just done had
>done my eyes good by means of the muscle test, which didn't convince me!

Rhetorical question: Why was it important to him that you believe as he does or accept his model?

>have a scheduler reminder that prompts me every 20 minutes to look up for a
>while and focus on something distant.

That's great!

>have much faith in them improving.

I sometimes feel trapped by my circumstances and thus prevented from taking all the steps I would like to empower my eyes. During those times, I continue palming and sunning and make strategic plans for the time when I can take the next step.

>contemplating sunning but am worried about getting wrinkley skin around my
>eyes!

Sunning is great. Often, as I get in my car to go to or from work, or when I'm out walking, I'll pause for a minute or more to close my

eyes, turn my face to the sun and drink in the warmth and light, sending it to my eyes and all over my body. If you are worried about wrinkles, you may be interested in Tai Chi or Chi Gung, both of which are renowned for producing youthful, vigorous bodies among dedicated practitioners.

>That's all for now, sorry it isn't better news. Perhaps someone else will
>jump in with something to correct my gloomy outlook!

Cheer up! You're OK just as you are.

Mark

P.S. By the way, do you think I should post this to the i_see list?

Oh, how I wish you were wrong! How I wish I were wrong. Maybe I am, I don't know. In any case, I am not dying to have my eyes "lasered".

Now, I think I can report a 0.25D improvement. This after six months of "intensified" VT, which basically means quitting using weaker glasses while reading and use just my bare eyes (i.e. use even more plus). Plus lenses in the form of weaker minus is virtually all I do in terms of VT for lifestyle reasons. But still I think this is the most powerful VT technique. The 0.25D is reported in accordance with the principle of conservatism (in accounting, Linda :), recognize losses, defer gains). It has not been verified by an optom yet. I am still frustrated that autorefractors are not as common in the US as they are in Europe.

I'd be interested to hear updated accounts on the progress others have made. Also, do you experience increased acuity fluctuation (to the best that you can judge) after starting VT?

Thanks in advance for any replies.

Stefan

Sorry if this has been asked before, but what happens if you try sunning through glass? Is it beneficial/harmful/no use at all?

Thanks
Caroline

> Also, do you experience increased acuity fluctuation (to the best that you
> can judge) after starting VT?

Before I started VT, I was aware of only a very slight reduction of acuity as I went through the day. I now get very large swings throughout the day. Sometimes the best is in the evening (unless I've consumed a couple of pints of cider :-). I'm aware that measurement of oneself as the experimental subject is a dodgy area, but most of the variables (e.g. level of illumination, distance, size of letters) are constant and the changes are far too large to be self-deception (probably :-)

I do feel quite cross with the Ophthalmic trade for not investigating VT. We have to call it a trade. Any profession would have jumped at the chance of having techniques at its disposal that are rational safe and simple. At the moment, we are all scrabbling around in the dark trying to find the most effective techniques. I started out with the book by Benjamin which I interpreted as a set of exercises, but am quickly going off that approach. I recently bought Bates original book and I think I've found my spiritual home.

I know its changing the subject, but the Bates approach seems to be very similar to the Alexander Technique. If you've not heard of it before, then its worth looking at. Its a process for eliminating

habits of reaction and mis-use of the body. I got interested when I suddenly developed severe neck pains, caused by bad posture and thought that there must be something better than pain killers. It works like a charm and has something going for it that most of the so-called Alternative Therapies do not. The Nobel Prize winner for Medicine in 1973 gave half his peroration on it. Even ophthalmologists would find it difficult to completely dismiss that. (on second thoughts, they wouldn't but who cares). Both methods stress that one shouldn't try too hard and my best results have always come when I've been in a "balanced state of rest"

Peter

I have gone looking through my old glasses and have found a pair that would be just right for + lens therapy while working on the computer. The problem is that I was quite young when I used them and was less than careful about how they were laid down. As a result, both lenses are scratched up at just the points I'm supposed to look through. Does anyone know of some method by which they could be repaired? The lenses are made of glass.

rest snipped

I know Tony personally and he is a fine gentleman. His approach as described in your post is a style taught in Natural Vision Improvement, and is not for everybody. Some love this form of feedback. I find when we are strong self thinkers, kinesiology or muscle testing may not suit our style. I personally do not use muscle testing and allow my patients to find their own solutions. Since you are in the Sydney area make contact with my friend Simon Grbevski at 2-597-3030. He is a behavioural Optometrist doing some fine things in the field of vision improvement. With regard to "doing eye exercises". I find living my new visual habits more important than whether I remember to palm or sun. My eyes tell me when to rest and look differently. More questions give me a shout. Have you read Seeing Without Glasses or The Power Behind Your Eyes?

Don't know about what Bates said, but many VT practitioners feel that part of the benefit of sunning is receiving UV light, which apparently stimulates certain cells in the eye. Glass (in the U.S. at least) is made to block UV light. This would limit the benefit of sunning.

[MODERATOR'S NOTE: FOR THOSE OF YOU NEW TO THE LIST, SUNNING IS TO BE DONE WITH THE EYES CLOSED, GLASSES OR NO. -- Alex <owner-i_see@indiana.edu>]

>Sorry if this has been asked before, but what happens if you try sunning
>through glass? Is it beneficial/harmful/no use at all?

I don't really know. My body knows that sunning without glasses is more relaxing and pleasurable. It also feels like my relationship to the sun is more direct. When I sun my eyes, I usually take off my glasses and watch and empty my hands of whatever I'm carrying. If I'm at home I may also empty my pockets and wear a hat. Since my personal focus is to pay attention to the energy, I don't want any metal distorting the flow, especially around my eyes. (I know it sounds metaphysical, but what's important is what you experience.)

Putting aside the glasses as you directly nourish the eyes is also a symbolic gesture.

The vision fitness lenses may be a reduction from +0.5 to as much as +2.00 from your conventional compensating lenses. It all depends how much you relax and let your inner vision direct your outer eyes to see. Have the doctor add plus lenses in 0.25 steps until you reach 20 /40. In most states and provinces you can legally drive with this level of visual acuity, although you will need to watch night driving and wintery weather conditions of rain and mist. I usually instruct my students to keep a stronger pair, say to 20/25 in their cars. I personally find that I can weaken the contact lens prescription more than the eyeglasses. In many cases the contacts are overly strong in older prescriptions. There are some progressive Optometrists in your area. Find those who offer vision therapy. Trust this helps.

Enjoy the summer light you I-seers out there.

Hi, I've been on and off my vision quest for the last 3 months.

I've come across an interesting advertisement for a workout and +diopter glasses of varying degrees. It claims 100% effective reversal of myopia and every form of defect known to man/woman.

The name is Vision Freedom and the address is:

<http://205.138.107.3:80/vision./>

I was wondering if anyone had tried this system out and to what degree of success before I dish out the \$100 that they want for the package. Is this another snake oil salesman preying on our problems?

Regards, Hoy Chow

The monetary cost of reducing glasses prescription has already been discussed. However, I face one special problem. I have some stigmatism (1.00D and 1.25D, regular, with-the-rule) and the cost of lenses with cylindrical component is much higher. If I go only for sphere (for distant vision), I'll face this nasty problem of seeing weirdly distorted images which will almost certainly frustrate me and most likely will stultify the whole thing. What should I do? However, all my weaker pairs are sphere only and I feel alright using them for near and "mid-range" tasks.

How successful have you been in reducing astigmatism? I recall someone (I think apparently the most successful on the list - Elena) reporting eliminating astigmatism altogether. Any experiences re astigmatism most welcome.

Stefan

This is in reply to Stefan's posting on 5/9/96.

I haven't yet seen tremendous improvement to my vision because of V.T. However, at this point and time, I don't have a lot of spare time to dedicate to eye exercises. Hopefully that will change this summer. I have, however, experience a lot more fluctuation in acuity. Also, my eyes seem much more relaxed and less prone to strain. There are days when my vision seems clearer and I am able to focus at a farther distance. On those days, I feel very positive and have a lot of faith in V.T. techniques. I have my down days too, and sometimes wonder if it's all worth it. I have also noticed that my sight is dramatically influenced by what I eat. But I have a number of food allergies which of course isn't everybody's case. I do think that this, however, could end up being a major key as to whether V.T. will help me in the long run, which simply means that I believe that if I can stay off certain foods, I'll end up reaping more benefits from my V.T. That's been my experience so far. I hope to hear from others.

I find I forget to breathe sometimes. If I find myself suddenly losing acuity, I consciously BREATHE for about a minute. That, along with blinking, usually restores the sharper vision I am becoming accustomed to. I find this is more useful, for me, than palming. Also, crossing my eyes seems to provide relief from astigmatism. Food make a difference, too.

-

Is anyone interested in supplying questions for the traditional school of thought on eye care? If so please read this email I've forwarded.

Hi, My daughter wrote questions which I posted to this list serve and mail to any/all the myopia webs I could find.

She gave her oral presentation yesterday - and school is out in two weeks so we'll probably know how well she did soon. THANKS to all who contributed to her knowledge.

I received the typical answer from this gentleman (Sek Jin Chew, MD, PhD) that myopia is with you forever... old school to think one could do anything through exercise to improve one's blindness lot in life...

I have found success with the exercises - palming and probably sun too much - I haven't given up my hard contact lenses, but when I'm not at work I wear MY DAUGHTER's old prescription and see just fine. So I'm a believer, and I'll try to be patient - as I saw it too Alex THREE YEARS to get to 20/20.

THANKS for all your help, I seldom get time to write, but I read each message and am always learning.

Kath

Recall that Astigmatism simply means more nearsightedness (or farsightedness) is one orientation of looking. Depending on the axis of the astigmatism you can determine which orientation or meridian of vision is more blurry by taking a narrow slit and rotating before one eye at a time. You will notice that in one orientation your perception is clear and the meridian at right angles (90 degrees away) is more blurry. It is this difference that is called astigmatism. Also, in conventional thinking we are lead to believe that astigmatism is caused by a difference in curvature of the cornea. In my experience and humble opinion, the corneal representation of astigmatism is an end result of warped perceptions of the mind. So with this in mind here is a technique I have found useful for equalising the perceptions of the two meridians. Use the swingball game mentioned in Seeing Without Glasses, and let the ball swing along the

meridian of the most blur. In this way you begin increasing your perceptual ability along the meridian of your warped or distorted perception. The result is less need for a lens to compensate for that blurriness. BTW. You might also consider what the blurriness means while following the ball. I find having the mind participate increases the power of the therapy. The outcome of all this is you can comfortably reduce the astigmatigmatic lens compensation in your glasses and there are usually no symptomatic side effects. Enjoy your less astigmatic perceptions, and let us know your results.

Visited the Optometrist today and discovered that my eyesight has deteriorated from -1.5 dioptres (both eyes) to -2.0 dioptres (both eyes). This is after wearing glasses which started out 0.5D weak for a year. Transition glasses clearly are of no use for me!

I visited an optometrist 2 years ago before a trekking holiday in Nepal. prescription was -2.0 both eyes (what its back too). I improved 0.5D in 4 weeks after the holiday (all walking - no computers for four weeks!).

Has anybody seen a machine like a microscope? You place one eye at a time to the eyepiece and by some magic, an image (such as a zebra) appears to move closer and further away for a few minutes - theory being that this helps with the flexibility of your eye muscles as you try to keep the image in focus. I saw one in Malaysia (Chinese made - like just about everything else) and think it was called a YP-9 eye-protector.

regards David

IMHO (based on never having owned anything BUT weaker-than-full-correction and/or a-lot-weaker-than-full-correction glasses... while unaware of their potential to be CALLED something, "transitional" or whatever, just aware enough of my physical/emotional/mental senses to figure out they were the only kind that could be humanly tolerated), they are not to be expected to be therapeutic at all. All they do is prevent someone who needs glasses (one of the unnatural "needs" created in people by innumerable, immemorial don't-you-dare-be-natural assaults on their integrity and "aliveness") from coming to greater harm via full correction. Which is not to say it's a small thing. If one needs (has been forced to "need") to take poison, it's only prudent to prefer a diluted, weaker solution to the pure, full-strength stuff...

David, I'd like to know, where did you get the idea about wearing "transition glasses"? Was it from I SEE? From one of Robert-Michael Kaplan's books?

> I visited an optometrist 2 years ago before a trekking holiday in Nepal.
> prescription was -2.0 both eyes (what its back too). I improved 0.5D in 4
> weeks after the holiday (all walking - no computers for four weeks!).

Could you please answer the following questions, which would shed some light on your case?

1. Did you wear glasses before your trek in Nepal?
2. When you got back, how did you determine your improvement? did you switch to a previous -1.50 prescription, or did you make another appointment with your optometrist because the glasses "felt too strong"?
3. What is the strength of your "transition glasses", -1.50 (-0.50 less than a base of -2.0) or -1.00 (-0.50 less than a base of -1.50).
4. Do your glasses have cylinders (for astigmatism)?

When we speak of "transition glasses" it is usually about glasses that are deliberately about a diopter too weak, and it is usually for those who absolutely cannot survive without glasses -- high myopes. They are never -- or at least never should be -- a primary form of therapy, especially for people with -2.00 or less of myopia. Remember, most myopes developed a diopter of myopia or sometimes even two without the encouragement of glasses. Therefore, we know that you can still become more myopic even if you're not wearing your full correction.

This means that even if you are undercorrected by a diopter, it's likely that that amount of "blur" in your life will not be enough to push your eye muscles into action. Myopes develop to be comfortable with a diopter or more of myopia and think of themselves as seeing just fine until their doctor tells them they "need" glasses.

Transition glasses for myopia will only work if you make them work, that is, take every opportunity to look at the smallest, most distant objects as often as possible.

Again, if you're starting out with -2.00 of myopia, and you want to reduce it, you will probably have to go without glasses for the most part of the day, only wearing your "transition" glasses for things like driving that require reliable clear vision.

No, I've never seen such a thing, but the principle is familiar. You can achieve the same effect by using reading glasses. Just put on a pair (available at any drugstore -- at least in the US) instead of or on top of your myopia prescription. Or simply take your myopic glasses off! The effect will be that the distant blur point has moved within arm's reach. Now take a picture of a zebra (or whatever) and with your hand move it slowly back front of your eyes.

An elaborated form of this idea is the basis of Brian Severson's "Vision Freedom" program.

You've got to spend hours and hours each week doing it if you want a significant improvement in vision. Otherwise, you can use the lenses as you describe, to "tune up" your distance vision when it starts slipping.

I am definitely of Mark's opinion, but just for interest..... when I went to see Tony-Paul Gaynor recently (Sydney, Australia), he looked directly at the (10am) sun for 5 minutes. He said that he could do it without damage because he had worked up to it. He said that 'normal' people would get damaged eyes purely because of the harmful things they had done like wearing sunglasses. Has anyone else heard of this opinion? If I hadn't seen him for myself I would never have believed it.

He said it is possible to work up to it by 'blinking around the sun' - blinking very rapidly whilst looking at the edge of the sun and moving your eyes around the perimeter. Again, I'm not recommending it, but I'm interested in hearing if anyone else has heard of this and is not worried about damage to the retina.

Ok - I think I can make a quick response to this one. Do you guys

remember when you where kidsa and you use to play with a magnifying glass in a sunny day to burn up stuff. Well, that's what happens (sorta) to the retina if you look directly at the sun. SOme people have strong retinas (I expect) that can withstand some abuse, some dont. I personally wouldnt do it....

cheers.

I've read of people who look at the sun with eyes open for long periods of time (as much as a whole day in a ritual context.) I always sun my eyes with eyes closed. I sometimes wonder if gazing at the sun with eyes open can be used in training extraordinary vision in some cases. I wouldn't try it, though, without a trusted experienced teacher (extremely hard to find).

Well, I wrote Public Citizen about my concern that patients are not getting informed consent prior to corneal surgery. They should be informed of all the pros and cons and alternatives, but that does not seem to be the case.

Also the surgery is held up to be a cure for myopia (and one medical journal I recently got said the laser is probably the most heavily marketted medical procedure in history). But myopes have more glaucoma and retinal detachment.

The surgery corrects the visual acuity problem (and even that outcome varies) but not the underlying stretch.

Public Citizen forwarded my letter to an ophthalmologist/neurologist who did not think there was a problem. But I wrote him directly about my concerns and asked for your prayers.

So here's what he said, "The points you raise in your letter of 4/24/96 about further research into alternative treatments for myopia are very valid. I have circulated your letter among my colleagues and perhaps those more expert than I will choose to respond. Thank you for your interest and for stimulating mine." - Jonathan Trobe from U of Michigan.

Again, if you are having sucess with improving your vision please write and inform:

Sidney M. Wolfe, M.D., Director
Public Citizen Health Research Group
2000 P. St NW
Suite 700
Washington, D.C. 20036

I have no e-mail address as yet. I think if the medical profession were going to give equal time to airing the views of behavioral optometry on their own, they would have done so already and I would have read about vision

therapy in a mainstream medical journal instead of from I book I purchased out of a gift catalog. Perhaps a consumer advocacy group can be persuaded to look at all the material with less bias and work to see that better medicine is practiced.

God bless America!

Julie Ralls, M.D., Family Physician

I know that I am going against the party line, but I sun with open eyes. I learned it that way from yoga. Late afternoon when the intensity is lower, I cover one eye and gaze with the other one in a circular motion about 30 degrees (width of my hand) around the sun. I do it when my old eyes get particularly blurry, one eye at a time, and it is a very wonderful eye strengthener. As long as I keep my eyes moving in a circle, no damage to the retina occurs. It has a very noticeable immediate reduction of blur.

I was under the impression that long term excessive sun exposure can contribute to cataracts. Animals have more cataracts in regions where the ozone layer is diminished. So you can work up to this for five minutes and feel no ill effects? But what about doing this regularly and long term effects? It doesn't sound like a good idea to me.

Caroline,

I live in Sydney and have been sunning (when our stupid weather permits!!) since January. I never would have believed that sunning can be of any good to the eyes until I tried it.

Background: I wore sunglasses for years because (for some reason) my eyes became very sensitive not only to sun light but also to normal daylight (even on a cloudy day).

I started my VT including sunning and in 4 weeks I could drive the car and go outside without my sunglasses. Now my Ray Bans are collecting dust in the glove compartment.

On average, I do the sunning exercise once or twice /day, 2 minutes each time and so far I have not experienced any problems at all in fact It has helped me a lot.

I hope this helps

george

I also sun with my eyes open following Huxley's description. I blink rapidly and swing my head back and forth while looking at the sun then palm afterwards. I also briefly look at the sun at sunset. I have never found sunglasses comfortable.

Breathing is a major key to silence. 90% of the brain's oxygen needs are supplied by the bottom 20% of the lungs. Shallow breathing (which is what most people do) helps to keep the wheels grinding in the head (the ID). Deep breathing is one aid to achieving silence.

The eyes are also an important factor. I have found that the eyes serve as controls of a sort. Staring, or fixating the eyes is bad. Gazing is useful.

The objective of gazing is to use the full field of vision available. Make yourself aware of everything within your view or area of focus. Allow your eyes to cross slightly and notice both images. Do not try to hold your eyes wide open as you will overwhelm yourself with image stimuli. Allow your eyes to roll slightly, avoiding image fixation. Breathe.

It is my experience that when I have been in a state of mental chatter, it is as if I am centered (off center) within head, pressing outwards. The higher the level of stress, the harder I seem to be pushing outward through my forehead/eyes. Chatter occurs with an outside or outward focus. Interpreted, it is a mental stance, a perspective of oneself as a separate(d) individual, apart from the world outside the body. The mental chatter is indicative of an organic perspective.

As I pull back from the outside world, I shift into a gaze. This shift is like the difference between looking at the world through a telescope (often through the wrong end) and viewing the world upon a large viewing screen. When we fix onto points of vision and stare, as in the telescope analogy, we lose details of the scene at large. When we gaze we are using the eyes from the perspective of the "mental theater." As I pull back, I can feel the shift of focus in my head go from my forehead/eyesocket triangle more towards the center of my head and towards the base of my skull. I become aware of my ears and of what I am hearing in the world around me. As this "movement of my attention" occurs, I feel down into my actual center (from my off-center head central) and I pull away from the sound of my chatter-wheels. I say wheels because once I begin to detach from my surface perspective and its ID, the words begin to sound more like musical notes which cycle and repeat. When I first discovered this "secret" mind-marker, and before I began reformatting my thinking program, the musical notes sounded more like grindings, or noises, than they did like tones.

This cycle may be perceived as color patterns as well as sound patterns if the eyes are shut, but if you work on this with your eyes shut, you may also have to work to keep your sleep program from engaging.

Breathe deeply your air, view don't stare, and become sound aware. These are keys to silence's lair. ~dav~

When you get insufficient sleep it means you get up with your nighttime, sleep-inducing hormones (like melatonin, for one) still circulating in your system, and with insufficient "daytime alertness" hormones that usually take around eight hours of uninterrupted sleep to build up to their normal levels. Some of those are, among other things, responsible for maintaining visual acuity. There are receptors for both kinds in the retina as well as in the brain. So when you get up after a short night's sleep your eyes wind up getting conflicting messages from the inside: "it's night" and "it's day" at the same time. Nothing works properly when flooded with conflicting messages.

Elena

Mark,

How long have you been gazing at the sun with eyes open? What trends or sensations have you noticed over the years?

It sounds from your description that you do not look with the sun in the center of your field of vision but 30 degrees off center, rotating the eyes around the sun.

Do you do other yogic exercises in the same session?

Mark (Jones)

>under "sunning" -- Alex]

I am pleased that the issue of sunning has once again surfaced. Firstly, understand that the sun DOES BURN thefovea of the eye when the recipient is unwell or unable to emotionally receive and integrate light through the retina into the autonomic nervous system. For a healthy person and a trained eye, looking toward the sun can be a wonderful healing practise, but BE WITH sunlight, even with the eyes closed. I personally trained with a physician of Tibetan Medicine who showed me how to have my eyes open, and look directly at the rising and setting sun for periods up to 5 minutes at a time. This training was a rite of passage and I DO NOT recommend it to my clients or students until they now how to BE with sunlight. I have found that my nearpoint acuity increases by two lines after such a practise. Most of us have too many belief systems and fears associated with letting in light. To receive light is to discover enlightenment, the light within. First, we must clear out the trash that prevents us from being in our own light in a healthy way. In the meanwhile, follow the sunning principles with the eyes closed and enjoy the wonderful colors of sunsets and sunrises.

Thank goodness summer is on the way here in Canada,

No, I read about them in a book which I think was written by a Barbara Goodyear.

>Could you please answer the following questions, which would shed some
>light on your case?

>

>1. Did you wear glasses before your trek in Nepal?

Yes, for about 4 years. During the trek I only wore fairly weak prescription sunglasses, if anything.

>2. When you got back, how did you determine your improvement? did you
>switch to a previous -1.50 prescription, or did you make another

>appointment with your optometrist because the glasses "felt too strong"?

Made appointments with an optometrist 2 days before leaving and one day after I returned. This was done deliberately as I expected some improvement after not

seeing a computer screen for 4 weeks (which was magic!) I'm a software engineer and can't really get away from them short of changing career.

>3. What is the strength of your "transition glasses", -1.50 (-0.50 less
>than a base of -2.0) or -1.00 (-0.50 less than a base of -1.50).

The glasses I had were 0.5D weaker than full prescription.

>4. Do your glasses have cylinders (for astigmatism)?

No.

Thanks for your comments re-transition glasses. For the moment I'll stick to

just wearing my glasses when driving. I refuse to use them now at work. I can feel my eyes straining to hold focus. Besides, my visions fine out to about armslength.

BTW, my optometrist told me I'm a pseudo-myope when I told her about how my vision improves after a good hard blink. I believe that optometrists know that vision can be restored without glasses.

regards ... David

-

I'm going for a eye test in two weeks. It's two years since the last when I asked for a reduction in my perscription to see if it would help my eyes. The numbers then were

-9.50 and -9.25 which include a +1.25 reduction.

Obviously I am very myopic and can do very little without my glasses, although I try not to wear them when I am out walking or a passenger in a car. I do feel however that my vision must have improved in the last two years as I can see very well with these lenses and quite often move them down my nose to reduce their strength. I am hoping the eye test will confirm my hopes and I will be able to get an even lower perscription. I will of course ask for another reduction on what he would normally perscribe.

At this level of myopia I realise that it would be optimistic to hope for 20/20 (I'm 30 now), but anything that will allow me to experience more of life without looking through plastic or glass is worth trying for.

I will of course let you know how I get on.

There is nothing wrong with being optimistic in fact its the best way to
be when doing VT. Why not go for the best other poeple have done it why not
you. I wish you the best of luck and look forward to hearing of your
results.

take care

Below is my progress so far:

		Left	Right
18/01/96	-3.00	-3.75	
17/02/96	-2.50	-3.00	
16/03/96	-2.50	-3.00	
19/04/96	-2.25	-2.75	
25/05/96	-2.25	-2.75	

As you can see there was no change from last month. I think that from now on the progress will be slow in the order of 0.25 per 3 months.

In 3 weeks I'm taking a long vacation for 4 weeks travelling around Europe and Canada and guess what? I'm not the only one looking forward to this trip, my optometrist said he would like to see me right after it!!!

I got some -2.00/-2.00 contacts for the trip in case I find the glasses slipping off my face in hot weather.

That surely says something.

that's all for now from DownUnder.

all the best

george

Just wanted to say congradulations on your success so far. You seem to have a healthy attitude about it. It is helpful not to get too hung up on how fast you improve. The healing process has an ebb and flow ,sometimes you make rapid progress and sometimes it slows down. You are doing great and best of luck. Enjoy your vacation and relax. I went away this winter to Mexico luckly I had been to this same area before so I didn't feel like I had to see everything as clearly as possible and therefore I took long walks in the bright sun without my glasses. Don't get hung up on having to see perfectly and keep up your VT.

Andy;

If you are a myope, ie wearing minus power lenses, then moving them down your nose does decrease their power.

An interesting section from *The Name of the Rose* by Umberto Eco, especially for everyone dealing with presbyopia:

<William slipped his hands inside his habit, at the point where it billowed over his chest to make a kind of sack, and he drew from it an object that I had already seen in his hands, and on his face, in the course of our journey. It was a forked pin, so constructed that it could stay on a man's nose (or at least on his, so prominent and aquiline) as a rider remains astride his horse or as a bird clings to its perch. And, one on either side of the fork, before the eyes, there were two ovals of metal, which held two almonds of glass, thick as the bottom of a tumbler. William preferred to read with these before his eyes, and he said they made his vision better than what nature had endowed him with or than his advanced age, especially as the daylight failed, would permit. They did not serve him to see from a distance, for then his eyes were, on the contrary, quite sharp, but to see close up. With these lenses he could read manuscripts penned in very faint letters, which even I had some trouble deciphering. He explained to me that, when a man had passed the middle point of his life, even if his sight had always been excellent, the eye hardened and the pupil became recalcitrant, so that many learned men had virtually died, as far as reading and writing were concerned, after their fiftieth summer. A grave misfortune for men who could have given the best fruits of their intellect for many more years. So the Lord was to be praised since someone had devised and constructed this instrument. And he told me this in support of the ideas of his Robert Bacon, who had said that the aim of learning was also to prolong human life.>

Hello, I am a 16 year old and was wondering what kind of lighting I should use. I typically spend about 2 hours a day at my desk doing homework, and I have a flourescent lamp hung about 3 feet above my desk. Is this good or bad? I get adequet amounts of lighting (probably too much lighting), though there is a significant amount of glare. I have heard that normal bulbs are better for the eyes. Any feedback wo7uld be greatly appreciated.

Greetings all,

I discovered the "I see" web page a couple of weeks ago, have been working my way through the faq, and have been searching for my prescription. I am grateful to have a community of supportive people help me overcome the curse of stronger and stronger specs until death. This is a longer post, but I am introducing myself, and follow-ups will be shorter.

I received my first pair of glasses in 4th grade (am 35 now) and remember having an eye exam back then. I think I was told that I had 20/70 in one eye, 20/200 in the other -- I believe the 70 and 200 are correct, but suspect I had the notation down wrong.

Off I went to Kaiser Hospital, Walnut Creek (Calif) with my mom, resulting in a pair of specs and an exhilarating drive home, as I read freeway signs at a long distance instead of when driving underneath. I became a full time glasses wearer, and spent the next decade or so feeling self-conscious about my appearance. Needless to say, the exhilaration wore off a long time ago.

I wore hard contact lenses between 1976 and 1986 except for one year when the ophthalmologist found blood vessels in the cornea (I think), called neovascularization. I stopped the contacts for a year, they went away and went back to contacts. During my stint with the contacts I had very minor changes in prescription, if any at all, and fell out of the habit of visiting the doctor to have the prescription checked. Prior to that time the

prescription changed regularly.

I have only had two eye exams and prescriptions since I stopped wearing contact lenses. One in 1989, when I first received correction for astigmatism (I think) and October 1993, when a stronger prescription was given. This last prescription was:

Sph -1.75 Cyl -1.25 -- 040
Sph -3.25 Cyl -1.75 -- 153

My vision in my right eye is much better than the left. However, even though I am right handed, my left eye is dominant. I use my left eye through a camera, microscope, and trap shooting at the range.

I started playing competitive table tennis a year ago. The first time in many years since I had played, I had noticeable difficulty focussing on the ball. I apparently have compensated.

I live in a fairly small college town, and the natural health practitioners I have spoken with and the health food store manager do not have any leads on optometrists. I am planning to speak with the doctor who gave me my last prescription, and hope she will write a prescription for "training glasses". She has an office adjacent to the Pearl Vision at the local mall. Would that impact her decision on whether she would help me?

Any suggestions on how to recruit a sympathetic optometrist would be helpful.

After my current status is determined, what would be a good prescription for training glasses? I presume I need legal driving glasses, ideally with minimal astigmatism correction (should I go for zero?).

Your experience, suggestions and encouragement are greatly appreciated. Will follow-up when I see the doctor.

Hi Folks,

Has anyone had experience with scintillating scotoma, sometimes called a "visual migraine"?

Here's how one text describes it:

"The disturbance reportedly begins centrally as a small, bilateral, circular distortion, and then expands, over a 20-minute period, into an enlarging three-quarter circle of brightly colored and flickering lights described as being 'similar to multiple small prisms laid side-by-side in semicircular fashion.' The disturbance continues to enlarge until it grows out of the patient's field vision."

I'm especially interested if anyone can offer environmental/dietary causes for this phenomenon and/or possible treatment.

Thanks,
Vince

A friend of mine has, he says, a great deal of trouble with floaters. There's many of them and they're very annoying, when the few minutes a night he has time to read - they crowd his visual field. Any thoughts on this subject? Any suggestions? All would be appreciated.

thanks,
freda

Bad. Fluorescent is the worst, actually. Not only for the eyes but for one's overall health. It's been implicated in depression in adults, hyperactivity in young children, and what-not -- correctly I'm sure, since someone who's sensitive to his/her environment/perception can more or less feel these things directly. I've always avoided flourescent lighting, long before I came across any adverse information, simply because everybody looked dead.

Older lamps invariably flicker (whether you notice it or not), imposing some additional adjustment strain on your eyes and processing strain on your mind.

Full-spectrum is the best. Ordinary, the second best. I've heard some good things about halogen lamps, and some bad things, too -- supposedly, they emit too much of other goodies in addition to light; I have no exact info/opinion on this one.

I can definitely vouch for the fact that bilberry does help vision problems. I have used both bilberry and eyebright by themselves and also as part of combination herbal formulas. I have found that bilberry does more to improve my vision than eyebright, but eyebright does a good job, too.

I have macular damage due to a detached retina. I also have focusing problems, contrast deficiency, double vision and extreme myopia. I have found that if I take the bilberry regularly, my eyes don't get as tired while using the computer, driving or reading. In fact, I have noticed my night vision while driving has improved. I take the supplement daily and take extra when I am having an especially hard-to-see day.

Sheila Sanders
sanders@mcn.net

Bilberry restores the visual purple in the retina, and is an antioxidant. I doubt if it will treat this blockage, where other herbs might well.

This is possibly another situation where turmeric could be used. Two Chinese herbs are used together for vision problems in the elderly: *Salvia miltorrhizae*/Danshen, and *Milletia reticulata* (or *Spathlobus suberectus*)/Jixueteng. Another herb that might be useful is Danggui (*Angelica sinensis*)("Tang Kuei").

On the European side, you might want to look at Rue (*Ruta graveolens*). It is often used to strengthen the eyes, and has Blood-moving characteristics.

In this sort of circumstance, it is best to choose *Blood-moving herbs* that will aid the entire health balance. Therefore, not just any herb for 'eye health' will be effective.

I appreciate your interest in my visual problems but my problems have nothing at all to do with nutrasweet or any of the other artificial sweeteners. I do not and will not consume any products containing any form of artificial sweetener and haven't used them for many, many years. When I did, it was in very limited amounts.

I am very conscious about only eating natural, whole foods and steer away from processed foods with preservatives, artificial sweeteners, colorings or flavorings. I also do not drink soda pop for the same reasons.

My daughter also had detached retinas in both her eyes....she is a vegetarian and also doesn't not eat processed foods or articial sweeteners.

I agree with everything you said about them and feel they are tantamount to consuming poison.

Sheila Sanders

What about herbs during pregnancy? I guess they don't get tested for safety in the same way as conventional drugs?

I second this one. It is better known as Dong Quai though.

>In this sort of circumstance, it is best to choose *Blood-moving herbs*

Ginkgo Biloba, definitely. Virtually hundreds of studies have confirmed its ability to improve blood circulation.

Check out http://www.eyenet.org/public/faqs/floaters_faq.html

No cure though. I've heard about using hypnosis for floaters but haven't come across any success stories. VT may help one learn to look "beyond" them. Antioxidants may help prevent new ones from forming. Acupressure and/or acupuncture may help.

Sunning & Double Vision

- To: i_see@indiana.edu
 - Subject: Sunning & Double Vision
 - From: paterson@ns.spclink.com (Steve Paterson)
 - Date: Wed, 5 Jun 1996 10:56:18 +0900
 - Sender: owner-i_see@indiana.edu
-

Sunning:

A few weeks ago there was a lot of talk about sunning. When I first saw these massages I thought they were hog wash. However, over these past weeks I have tried it for myself. I was hyper-sensitive to bright light - but my night vision was excellent - and had to wear sunglasses whenever outside. Because of this sensitivity I closed my eyes and faced the the sky and relaxed, never directly in the sun as it was too painful. While my eyes were closed I would try and see the light on my eye lids and notice the colors. Now I can fairly comfortably do this facing the sun, with my eyes closed of course, and on sunny days I don't need to wear my sunglasses. BUT, does sunning affect night vision capabilities?

Double Vision:

I'm a computer graphic artist and animator so I look at monitors most of the day. I don't wear glasses and my vision up until this time for both eyes was perfect 20/20, here in Japan I was rated 2.0 by an ophthamologist. Last year during November/December I was responsible for an intensive project, often working late into the night. During this time I had noticed my left eye tiring quickly, my right eye was fine. Then gradually I noticed double images if I looked only with the left eye, especially when I got really tired. I went to an ophthamologist here, in Japan, and they said I have astigmatism - at 120 degrees - but it's unusual for just one eye to get it. They have suggested I get prescription glasses. NO WAY!

Sometimes when I can get really relaxed and open my left eye everythings okay for about a minute or less then it just goes back to double vision. After going online and reading some article on ISEE I've been trying

palming when I can. From the email I've been reading I realize that my problem is insignificant compared to many people. But, I want my perfect vision back.

Does anybody have any suggestions or directions? And has anybody heard of PRIO? They're supposed to make prescription glasses for people who use computers. They say the glasses keeps your eyes relaxed. Does anybody use these glasses?

I look forward to any information. Thanks.

Warm regards
Steve Paterson

Sheila: It sounds to me like you're on aspartame marketed as NutraSweet, Equal, Spoonful and no telling what since the patent has expired. It causes retinal detachments, double vision, blurred vision, macular degeneration, and a host of vision problems including blindness. The reason is the methanol in it converts to formaldehyde in the retina of the eye, and destroys the optic nerve. Most people who have been using it for any length of time already have some of these symptoms.

At one time I put Dr. Roberts position paper on aspartame and the eye on the I-See Network but its been some time ago. So you might want to read it off our auto-responder unless Alex wants to put it on again. Its been sometime.

To use the auto-responder simply email me and put sendme help in the subject line for a directory like this:

Subject: sendme help

Then when you get a directory you simply put sendme again in the subject line with whatever file you want to access typed exactly as in the lefthand side of the directory. Example:

Subject: sendme diabetes-aspartame

Be sure to read the Joyce Wilson story because she did go blind on NutraSweet. Also there is a post titled Embalm Or Not To Embalm which is a testimony that came in from the lady who wrote Blinded Sight when her husband when blind on NutraSweet. Now people are dying of the formaldehyde content. Also we can email you our warning flyer with publications and symptoms.

Dr. Roberts now has his publications on net and he has excellent tapes on aspartame that will tell you about the eye. He is the world expert. You can get them by calling 1 800 -814-9800 Mondays, Wednesday and Fridays after 8:00 A.M. or his net is:

<http://www.icanect.net/sunpress>

Also Mark Gold has an excellent site which has information on aspartame:

<http://www.tiac.net/users/mgold/health.html>

I've had information on aspartame but its been sometime ago when it was on the I-See Network. And Alex has some on his web - NutraSweet - Poison to the Eye.

So the reminder is timely now for new ones and remember that aspartame is now in regular products like Fresca Wrigley's Winterfresh gum.

I think they know we have been warning all people off this poison all over the world and they also know its addicting. Its now is in not only over 7000 products in over 90 countries of the world but in baked goods, over the counter drugs and even prescription drugs. Be warned.

Regards,

Betty Martini, Founder Mission Possible (the people trying to warn the world and get it off the planet)

To get more information on aspartame, email betty@pd.org as follows:

Subject: sendme help

The subject line must be typed exactly like the above line.

Betty Martini	1. Take the 60-day No-Aspartame test
Mission Possible	and send us your case history.
PO Box 28098	2. Tell your doctor and your friends.
Atlanta GA 30358	3. Return Aspar-Poisoned foods to the store.
USA	(Nutrasweet(tm), Equal(tm), Spoonful(tm), etc)

We are dedicated to the proposition that we will not be satisfied until death and disability are no longer considered an acceptable cost of business.

I wear $-.75(L)$ and $-1.00(R)$ "training" glasses, usually at night. I have noticed that the lenses, especially the left, give faint images of lighted objects due to the low power. At night, rather than straining to see an illuminated sign in the distance, I have noticed that I can look at the image of the sign in the lense instead, and see it crystal clear. This may work for prescriptions of similiar power.

Interesting. A few years ago I took some of my old pairs of glasses to my
new optometrist so we could chart how my prescription had changed over the
years. (This was before I was into VT and keeping track of these things
myself.) We found that, without any form of VT, my astigmatism had shifted
on its own, several times, about 2 diopters overall! The largest shift was
in my left eye... You might want to consider palming, sunning, and general
relaxation (eg. meditation) rather than getting glasses. Also, I've heard
(no studies I can refer to) that astigmatism is related to spinal
imbalances; it might be interesting to check with a chiropractor or other
body worker to see if sitting at the computer for long hours knocked your
spine out of whack.

But since your glasses are only a couple of inches in front of your eyes, I wonder whether this isn't training your eyes to see in the near, perhaps putting you on a treadmill to deepen your myopia? Almost the opposite of Bates's admonition to look at a far known object...

Hi everyone,

I am considering getting myself bifocals without being presbyopic yet. Ideally the thing I am reading should be at my distant point of clear vision but I can't wear glasses that give me this vision in the workplace because I have to interact with other people and I want to see them. Bifocals may help eliminate this problem.

Does anyone have experience with bifocals for VT purposes? Any troubles seeing with them like mixing fields, inadequate D-cell size (the lower part of the lens), or whatever? I have never worn bifocals.

Any problems getting them prescribed? How about progressive lenses, are they better than bifocals?

Thanks in advance.

Good point. However, Bates also talked against straining the eyes. My point is that its better to relax the eyes and look at a focused near image than to strain at trying to see a far one. I would agree that one should not become reliant on this trick. In the meantime, you're saving your eyes from the hazards of a stronger prescription.

Double vision, astigmatism, myopia and all that stuff

- *To:* "I_SEE" <i_see@indiana.edu>
 - *Subject:* Double vision, astigmatism, myopia and all that stuff
 - *From:* "George Tohme" <PolySoft@msn.com>
 - *Date:* Thu, 6 Jun 96 07:11:08 UT
 - *Sender:* owner-i_see@indiana.edu
-

sometime ago I asked about the fact that I see double images in both eyes when I look at an object outside my clear vision field. I'm still not clear whether it's because of myopia or astigmatism.

The images occur one next to the other (not on top or at an angle) so if I'm looking at the letter T I see it as T| (the vertical line is doubled).

Here's what I think:

1- the double image is due to some vertical pressure or sideways pulling on both eyeballs which resulted in having 2 horizontal focal points in each eye.

2- when I practice vertical shifting I notice that my eyes do not move in a smooth vertical line. the movement is sort of like this (it seems to happen when I'm shifting up) :

```
|  
|  
)  
|  
|
```

As you can see (I hope) that eyes move straight then pull to the right and then back in a straight line. I'm sure that if I can get rid of this double image my vision will improve dramatically because when taken separately, each image seems to be quite clear but because they're too close the whole thing becomes very blurred.

Questions:

1- is double vision caused by myopia or astigmatism?

2- Is the above indicate astigmatism?

3- are there any 'good' exercises to overcome this pulling?

thanks

george

I read something like this in an old ophthalmology text-" it was proposed that the lack of appropriate lighting contributed to myopia. However, over the decades, indoor lighting has improved considerably yet myopia continues to increase. Therefore, it is clear that lighting does not contribute to the cause or progression of myopia"- So clearly this has been extensively studied by the modern scientific community with highly technical equipment (their brains) but I'm not sure that the equipment was turned on. From the epidemiology, myopia increases with indoor , close-up work. How much does the indoor part contribute?- I'm not sure but I know for a fact that my vision is much clearer outdoors or in natural lighting when working near a window. I would just say get outdoors a lot. Be a jock. If you work indoors, try to get a window with a view. I don't think there are any real studies on this so you are left with intuition and common sense and your own experience.

You can get a referral for a sympathetic optometrist by calling the Optometric Extension Program Foundation in Santa Ana, Calif at 714- 250-8070.

I like the end of Dr. Sherman's article, Myopia can often be Prevented, Controlled or Eliminated, Journal of Behavioral Optometry, Vol. 4, No. 1, p 16 1993. He recommends several points- wearing reading glasses to read, good lighting and no distance lens correction. Obviously you have been using distance correction for years. you could just take your old prescription and white it out and drop it down by 1/2 diopter on both sides. I've been doing focusing exercises which seem to speed up the improvement in my vision, though I don't understand the mechanism for this.

An interesting article in Brain/Mind Bulletin references work by Hanna and Antonio Damasio. The following is a brief section of the article:
"Words and concepts do not appear to exist explicitly in the brain but are instead reconstructed each time we need them. Moreover, the process is uniquely personal to each of us; our experience helps us constantly remodel our verbal circuitry.

"We are suggesting that [the retrieval process] is extremely dynamic and linked to each individual's experience," Damasio said, "Our knowledge is built on bits and pieces of many aspects of a given thing - shape, color, movement, taste. These things are not going to be laid down in one single place."

The Damasios are well known for their work with brain-injured patients, including many with bizarre visual problems caused by strokes or accidents. In 1989 they reported that vision, like verbal recall, appears to be a complex, collaborative process drawing on many brain regions. (See Brain/Mind, January 1990.)

Their experience has shown them heartening evidence that many verbal problems can eventually be corrected, apparently through the brain's inherent capacity for compensation."

I'm requesting the referenced issue and will post from there if anyone is interested when it comes in.

regards,
freda

Here's another item from the catalog I mentioned in a previous post (Healthhouse USA 516-334-9754).

Clip-on plus lenses! They attach to the front of your glasses and flip up when not needed. Healthhouse USA sells them in "2x magnification" (#36412) and "3x magnification" (#36413). I think they mean +2.00 and +3.00 diopters. Anyway, they sell them for \$4.99 each or 2 for \$8.00.

KGH

I just found an item in a catalog called "Healthhouse USA" that may just be the answer to your question. I haven't tried the product, but it sounds promising...

"Amazing lens polish virtually wipes away hairline scratches and abrasions -- makes your glasses look as clean and sharp as the day you bought them. Saves money on replacement lenses! Protective coating also helps prevent new scratches from re-occurring. Works on sunglasses too!"

There is a picture of what looks like a glue-stick, labelled "Clean-n-Brite", polishing a spectacle lens. The product is listed, however under the name "Eyeglass Saver", item #37370 selling for \$4.99, or 2 for \$6.99, or 4 for \$9.99 (plus shipping). Call 516-334-9754 for a catalog or to order (no toll free number).

It's been quite some time that we haven't heard about Elena's progress. She is apparently one of the best "performers" and could be an inspiration for all. I know it's summer time (in the northern hemisphere) and the open calls, but if you can, Elena, tap in a few lines on how you are doing visionwise.

Btw, have you checked my latest post on sci.med.vision : "'New' myopia paradigm on the rise"? Mainstream science finally begins to realize that corrective lenses for myopia possibly harm the eyes. We may expect some real changes in myopia management.

Best,

Stefan

Thanks for asking. I was going to post some sort of an "anniversary" update anyway: I've started VT exactly one year ago...

The initial changes in my vision were rapid; I was excited, wanted more, and started exploring in every possible direction. Right from the start, I viewed myopia as a systemic event rather than an isolated symptom, but a "gut feeling" wasn't enough -- I still didn't know what systems were involved, nor what agents or processes affected them and how exactly. I gradually accumulated a handful (or, rather, a "mindful") of jigsaw pieces of theories and was juggling them every which way, yet the ultimately convincing picture eluded me. I began to suspect, ever since I realized that striking parallels exist between the way I see and the way I think, that a totally clear understanding of myopia would also mean the end of myopia, a complete and permanent cure. Words that can function as abstract notions but originated as references to our primary perceptions ought to be taken very literally. Clear is clear. (However, someone who's never been myopic can't be clear about what myopia is, any more than someone who's never been sighted can be clear about what sight is. A true expert in anything ought to be an insider -- pun fully intended.)

The very origin of my "cognitive style," which is "fuzzy" more than "crisp," is purely physiological. It's the direct outcome of being very myopic for many years yet very intolerant of glasses, living largely in a blurry world,

and therefore unwittingly stimulating and refining intuitive, fuzzy skills: the ability to analyze incomplete data, to infer and project rather than define and limit, discover patterns rather than concentrate on the details, and so on. (For instance, some of you may have been outraged by my handling of the anatomy of the eye, complete with a "visible ciliary" and gravity affecting the shape of the sclera. The reason behind this peculiar description is not that I'm unable to learn what an eye really looks like, but the fact that precise statements haven't helped me to "study" my eyes as subjective reality, within their own element so to speak, rather than as a symbol or sign or description or a set of measurements or any other product of secondary representation. I studied my eyes by trying to become aware of the minutest, indeterminate, non-definable sensations, reactions, subjectively felt changes, etc. So I had to have a fuzzy picture of the eye in my mind -- otherwise I would have been overwhelmed if I tried to approach it simultaneously in linear and non-linear, non-intellectual way. I know I have a trabecular meshwork, for instance, but before I'm perceptive enough to feel and/or control it I don't need it... so out it goes, together with a lot of other stuff. Initially, I could only work with a very basic eye: it had The Center and The Periphery. Later on, it acquired The Eyelids, first the upper and then the lower. Gravity started to mean something subjectively too, so I threw it in together with the back of the sclera. And so on. When I've processed the whole eye it will be complete -- although there's no guarantee that it will resemble the one in the medical atlas. But the one in the atlas is nothing like mine -- it's a symbol, and my eyes are reality. So I guess I'll stick with my own kind. I like to be real.)

The very complexity of myopia warrants a nonlinear approach. Can't resist quoting Lotfi Zadeh, the father of the mathematical theory of fuzzy logic: "When complexity strikes, precise statements lose meaning and meaningful statements lose precision." Sounds as though he's describing the route my vision improvement has taken. I was the least successful when I tried to get "objective," "precise" or "scientific." At some point, I suddenly "heard" and passionately rejected the subtle message of the self-serving dogma we've so often been manipulated into accepting as "scientific approach": "you are nothing, therefore you perceive, feel, and think nothing, unless/until an expert in the field explains to you how to do it scientifically and objectively. Or unless/until you stop being yourself, you little nothing, and become an expert in the field. And now just go ahead and love your choices."

Btw, the very fact that I felt compelled to share my experiences and ideas with the sympathetic i_seers (as well as occasionally provoke, or be provoked by, an opponent), was part of some hard-to-determine changes in my thinking that both resulted from and gave rise to changes in my vision. This desire to express myself was already part of the overall change, in itself a sign of some "systemic" developments. It was primarily an

emotionally motivated attempt at self-explanation, not unfamiliar to some of you, too, especially those whose eyesight or at least "style of seeing" started to change. Asking someone to become "more open to feeling" is meaningless: feeling is part of physiology and is not governed by intellectual decisions to feel or refrain from feeling a certain way (unless you fake it); a change in eyesight, on the other hand, is a change in physiology, and any number of coincident unexpected, unpredictable emotional responses is GUARANTEED. For me, it's been a roller-coaster year of inner emotional events (some of it must have spilled into my posts, without doubt), and I thoroughly confused myself right before... right before I confused myself even more... before arriving (recently) at something more meaningful and closer to a workable theory than anything I ever thought or imagined before. Something for the second year's explorations.

In the meantime, here's an update of my progress.

1. Daily spontaneous clear and "semi-clear" flashes that last up to a few hours. The best acuity experienced in a spontaneous clear flash 20/20; the longest duration of uninterrupted 20/20 vision -- about 5 minutes in a row; 20/40 -- about 30 minutes; with constant interruptions, "on and off," 20/60 - 20/80 typically lasts all day. (Compare to approx. 20/1000 a year ago.) During "interruptions," vision fluctuates widely, sometimes getting nearly as bad as the initial pre-VT figures but never getting "stuck" there.

Floater seem to play a major part in fluctuations. I never paid attention to them before my vision started to improve, but I know they were there a long time ago because I occasionally saw them, typically on a sunny beach, with my eyes closed. They have very definite shapes and are absolutely recognizable, so when I began to be bothered by them I knew they were those old buddies, not something newly acquired. But I began to see them nearly constantly; eventually I figured out that they just used to be blended into the blur, whereas when the blur decreased they became perceptible. I'm thinking of Dr. Kaplan's mentioning a post-PRK patient who developed a large and extremely annoying floater. I think what might have happened to that person was not that he developed it, but that he was able to perceive it for the first time because his blur was gone. I now see them when wearing glasses, too, but then they don't interfere much with anything; usually, I notice them only if I want to check whether they are still there. But without glasses, I can't ignore them because they can make or break clear vision. In fact, I don't notice them only when I relapse into "bad" vision. Reestablishing a clear flash immediately reestablishes those bastards, too, and then episodes of 20/20, for instance, last till a floater moves across the center of my vision. They are responsible for a large number of other "special effects"; learning to handle them is something I have to invent from scratch, since no VT activities have any impact on them. I'm trying to learn to perceive them with peripheral vision only (hard as hell, since I have to teach my new and capricious central vision to selectively ignore them), and have had some successful moments (thirty minutes of 20/40, in

particular) when doing an exercise that involves constant awareness of peripheral vision. (This one is excellent for inducing a clear flash per se: walk with your eyes loosely on the far horizon, as if looking absent-mindedly at some tiny spot there but not trying to see it, at the same time noticing the movement of objects and space on your both sides simultaneously. Don't look at anything in particular; let it slide by. You might want to imagine that you have three eyes rather than two, the central one fixed -- loosely of course -- on the horizon, the ones on the sides taking care of the side view, all of them in your awareness simultaneously. Don't adjust your facial expression "so as not to look spaced-out": do it in a pedestrian-free zone and don't adjust or monitor anything about yourself. It's important to let your face express whatever it chooses to. If you have to pay attention to maintaining a dignified look in addition to the original task, you're likely to fail.)

2. Voluntary control of vision: can get a clear flash anytime I want. The shortest duration of the voluntary act of initiating a clear flash -- a second or two (one "controlled" blink); the longest it takes is a few minutes. Rate of success 100% in daylight. Nighttime vision control is unimpaired in good lighting, but both spontaneous and voluntary clear flashes are a lot harder to come by in the dark.

My blinking techniques have nothing to do with "refreshing" my eyes or "lubricating them with tears" -- I mean, all of the above is also true but the role of a tear film, for instance, is nonexistent -- a blink does not create a tear film thick enough to influence refraction in any noticeable way (unless one is crying I suppose). The art of blinking (a few months of experimenting) is now 1)an exercise in ciliary/extraocular muscles control; 2)massage for better circulation; 3)the skill of making expressive emotional (i.e., the only physiologically sensible) movements with the eyes and eyelids (like in the Indian dance tradition where the eyes make exaggerated movements specific to expressing a particular feeling); 4)a quick alternative to palming (a few prolonged, "stuck" blinks every 15 minutes or so -- unless I forget of course. The first inkling of eyestrain sensations in front of the computer is treated as a reminder.)

3. "Objective figures in diopters" meaningless, due to constant fluctuations of vision. Minus lenses of ANY POWER make voluntary control difficult and prevent spontaneous clear flashes. I find "objective measurements" as we know them rather inadequate in general and totally irrelevant in my particular case. All they demonstrate is that my eye muscles respond to an artificially fixed focus with fixed immobility and loss of own power of adjustment. Measuring my vision by conventional methods right now would amount to measuring my ability to walk with my ankles chained together, "objectively and scientifically" demonstrating that my performance would depend on the length of the chain, the tightness of the cuffs, etc. Sure it would. However, someone's ability to walk in chains may have nothing to do with this person's ability to do the plain old walking per se.

4. Having started some yoga for the hell of it, gradually grew enthusiastic and am on the way to becoming a fairly proficient "yogini." Breath control (pranayama) exercises may prove to be one of the most important parts of any VT program after all.

5. What, far as my present understanding is concerned, WON'T work or at least won't have lasting effects: hypnosis, NLP, psychoanalysis, any form of traditional psychotherapy -- in other words, anything that is aimed at modifying BEHAVIOR without addressing its physiological and, first and foremost, deep emotional (including non- and pre-cognitive) energy sources in the brain. Vision is not behavior. It has nothing to do with how you behave as an adult. It has everything to do with how you FELT INSIDE as a kid -- or even as an infant. But that's my "second-year concentration."

>

>Btw, have you checked my latest post on sci.med.vision : "'New' myopia >paradigm on the rise"? Mainstream science finally begins to realize that >corrective lenses for myopia possibly harm the eyes.

Yes, thanks. Cool. If I were still in the grip of the illusion that people are rational and that enough "scientific facts" can change someone's erroneous beliefs (even though -- gasp -- those beliefs happen to provide this person with self-importance and a good income), I would at this point expect a couple of apologies from some sci.med.visioners, and Alex, about a hundred thereof. Watch it not happen though.

> We may expect some real changes in myopia management.

I don't think so.

Best wishes of good luck and clarity to everyone.

Elena

The back issue arrived. Not as promising as I hoped but interesting:
Here's the article referred to last time:

Color and shape are thought to be processed by different parts of the brain. And according to a U of Iowa neuroscientist, some visual-recognition disorders may result from disrupted interaction between brain channels.

Antonio Damasio said new diagnostic methods may help trace bizarre visual disorders - for example, the ability to recognize natural objects but not manmade things - to their neurological roots.

Damasio told the Phoenix meeting that he and his colleagues have identified a neurological network that underlies vision. Rather than being a straightforward, sequential process, he said, vision apparently occurs through cross-talk between brain sectors receiving different aspects of images.

He and several co-workers came to their conclusions after studying some 1,500 patients with visual disorders. Most had suffered stroke or other brain damage. In particular, he examined patients with achromatopsia (loss of the ability to detect color) and prosopagnosia (inability to recognize or learn faces and objects).

The two disorders, D said, seem to be caused by a loss of neurons in the specific brain areas - sections of the cerebral cortex - that are thought to be needed to process color and shape. The neurons most often die from lack of blood caused by stroke.

Several interesting aspects of the disorders supported the idea of separate visual pathways. In patients who cannot distinguish between animals but recognize manmade objects - or vice versa - it may be that the difference in shapes is responsible. Whereas manmade objects have sharp and often symmetrical angles and shapes, natural objects are much more haphazardly designed.

In addition, although they have not outward recognition, prosopagnosia patients show strong physiological response to familiar faces but none to people they have never seen before.

Hi all,

Over the past year people have been telling me that I seem to squint alot and that my eyes are very narrow. I've been dwelling on that and other aspects of my vision. One day while I was riding my bike into Uni I was thinking about this and I tried widening my eyes and my vision improved. As long as I kept my eyes open wide but not staring my vision stays sharper.

Have any others experienced this? or have any thoughts on this? or can explain this? And, should I be doing this?

Keeping my eyes wide open
Alistair

New Treatment Option For Intractable Amblyopia (Lazy Eye)

- *To:* i_see@indiana.edu
 - *Subject:* New Treatment Option For Intractable Amblyopia (Lazy Eye)
 - *From:* Mark Herold <HEROLD@brk.bfg.com>
 - *Date:* Tue, 18 Jun 1996 16:39:57 -0400
 - *Sender:* owner-i_see@indiana.edu
-

Hi fellow I-SEEers and Alex,

About year ago I started my own personal Internet search for data relating to amblyopia (Lazy Eye). This search was driven by the need to see all possible options being explored in the treatment of my daughter's (Melissa) amblyopia condition. In the following text you will find a brief description of the history and option that I have found in regards to her intractable amblyopia. For the record I am not a medical doctor, I 'm just a father seeking out all options for the treatment my daughter... I would like to share what I have found so far.

Basic Background:

Melissa was about age 5 when she was diagnosed with amblyopia, at that time her right eye had the visual acuity equal to about 20/400 sight... this was after here vision was optically corrected with glasses. As a result of this patching was prescribed and steady improvement was made over a period of time (about 6 months) but eventually her improvement plateaued at about 20/100 visual acuity. This acuity level, in her right eye, has remained for over 6 months now, and she is now slightly over 6.5 years old.

Information Located:

After posting a number of information requests, and receiving a plethora of information, I finally was pointed to research that was being conducted at the Ohio State University in Ohio-USA(for detailed information see the proceedings of the 13th Eye Research Seminar conducted by Research to Prevent Blindness - article Treating Older Children With Intractable "Lazy Eye", p37-39, author: Leguire L.E.). Basically real improvement appears to be possible for children that have stopped improving under standard patching therapy for Amblyopia, this includes older children - such as ones in their teen years. The method involves using patching in conjunction with a very low dosage of Levodopa/Carbidopa over a 7 week period.

Present Condition:

At present Melissa has just started the treatment, this is being conducted under the direction of her ophthalmologist. Her exact condition before the treatment started has been detailed and in about seven weeks we will see just how well this has worked out for her.

I hope this will be useful to someone else out there.

Hello:

I'm new to the list.

I joined because I have problems with double vision.

One eye focuses higher than another and to one side.

I've used the acomotrack machine and for the most part corrected my myopia.

But the doubling has not gotten better and has in fact gotten worse. I've been doing exercises with eye patches with little success.

Immediately after I remove an eye patch, I do not have doubling, but it quickly (within seconds) goes back to double. I cannot hold it there.

I'd be extremely grateful if anyone can help me.

I live in Colorado and used to spend all my free time viewing and photographing wildlife. I've had to give this up because I can't spot animals like I used to.

I've noticed much the same thing - my eyes normally are not open very wide, but on forcing them a bit wider my vision (and that sort of "sense" of what's around you) improves considerably.

I get the same thing if I pause for a moment and relax my face. Perhaps what's happening is that my face is usually in a tense position - cheeks/below-eyes pushing up, brow pushing down - and I just need to learn to keep it more relaxed.

I dunno. Any more thoughts would be interesting.

I find this kind of information extremely valuable - thanks. Its always easier to believe someone you "know" than a reference in a book. (Thats a strange thing to think of someone thousands of miles away, but you know what I mean)

```

```

I've not experienced any such problems, although I do have several floaters. My fluctuations seem to come from a lack of fusion between the eyes - they seem to be fighting each other.

I've just discovered blinking and was surprised at how effective it
can be, until I saw a diagram of the muscles controlling the eyelids,
they pass right over ones that Bates reckoned controlled
accommodation.

Interesting. When I was about 10, before I had any myopia, we used
to see who could hold their breath longest and I always won. When we
tried again in my middle teens I didn't even come in the top half and
I had developed myopia.

Fully agree - this might explain why the "professionals" have such
difficulty with VT.

> Best wishes of good luck and clarity to everyone.

>

> Elena

One would like to think that "good luck" had nothing to do with it
and that Bates' hope that better approaches would be developed to
remove mental strain would have been achieved by now, but best wishes
all the same.

```
SKlues2470> I'm new to the list.  
SKlues2470> I joined because I have problems with double vision.  
SKlues2470> One eye focuses higher than another and to one side.  
SKlues2470> I've used the acomotrack machine and for the most part  
SKlues2470> corrected my myopia.
```

Double Vision is not something you read about a-lot on this list. Most of us have probably heard of the accomotrak machine. How did you get access to it?

```
SKlues2470> But the doubling has not gotten better and has in fact gotten  
SKlues2470> worse. I've been doing exercises with eye patches with  
SKlues2470> little success.
```

I was always told that they wouldn't correct me (with glasses) back to 20/20 since the doubling would get worse (or at least bother me more). I understand that suppression is usually more of a problem than doubling. Thats what I do: rather than let me see double, my eye suppresses the second image. Actually seeing double is quite unusual.

```
SKlues2470> Immediately after I remove an eye patch, I do not have  
SKlues2470> doubling, but  
SKlues2470> it quickly (within seconds) goes back to double. I  
SKlues2470> cannot hold it there.
```

Actually, that is a start. Some people cannot hold the single image at all. You may need to advance to working with both eyes at the same time. When I began my therapy, I worked only one eye for only the first four weeks. Now I work them together

SKlues2470> I'd be extremely grateful if anyone can help me.
SKlues2470> I live in Colorado and used to spend all my free time
SKlues2470> viewing and photographing wildlife. I've had to give
SKlues2470> this up because I can't spot animals like I used to.

I would suggest that you see a behavioral optometrist or one who performs Vision Therapy. There are one or two who hang out in sci.med.vision who can refer you or you can do your own research.

Also, I recommend a book called "20/20 is not enough" for some more background on the subject. It is written by Dr. Siederman and Dr. Marcus and Dr Marcus is my optometrist now (even though he's a two hour drive away).

Feel free to contact me privately via email for more information.

Hope It Helps.

Peter,

thanks for your reply and for corroborating some of my findings!

>One would like to think that (snip)

>Bates' hope that better approaches would be developed to

>remove mental strain would have been achieved by now

I've been able to identify some that look promising. Interestingly, they've been as much silenced, ridiculed, distorted into some obscure "alternative" poor relatives of science, and ultimately marginalized by mainstream psychology as Bates had been by mainstream ophthalmology.

Well -- by now I know better than to be discouraged by the fact.

I'm going to post on the subject eventually.

Elena

>Welcome to the i_see mailing list!

Why thank you! happy to have found your list.

A quick intro and some questions...

My name is Bill Stender, 38, living in the San Francisco Bay Area.

I first got glasses for nearsightedness in the fourth grade 1968. I first discovered that my eyes werent permanently this way back in 1976 after laying on a lawn waiting for a class, i woke up with a start and looked for the clock tower and saw that i had about 5 minutes to get to my class, i grabbed my bag and got up and then noticed my glasses sitting on the lawn. I was seeing things perfectly well. I grabbed the glasses and headed for class, leaving them off and really freaking out that i was seeing everything fine. The myopia started reasserting itself, but i made it all the way through my math class (a very stresful one) and could read the board from 30 feet.

This was a real shocking experience and i started trying to figure out how to reclaim my vision by designing eye exercises to 'strengthen' my eyes. This didnt work out and eventually it was business as usual for two years before i came across an article which mentioned Bates work and method. I found books and read up on all of it and started working on it with much enthusiasm.

Now after 18 years, I still wear glasses, though i am of a bit lower

prescription than i was that day on the grass. I have made a couple of pretty good advances over the years, once even going two weeks without wearing them at all-even while driving, but the vision was never perfect and the stress of my life caused me to go back to them.

I have had a major goal for a long time to finally completely restore my vision, but the attempts i've made have always fallen short. There is an emotional/psychic component which seems to form a wall. Is there much discussion here about these matters? I imagine that could get boring for many, but that seems to be the last mile for me. I have the techniques down pat. I can get my vision to very good very quickly, but cannot maintain it on a day to day basis.

The thing that inspired this recent push, which produced the discovery of the website and this e-list, is that my son came home from school with a recommendation that he get glasses by the school nurse. I snapped to attention and said that we could straighten it out. This was met with some skepticism, considering i wear glasses and have known about this for so long! BUT now i'm motivated for him as well as for me, I need to finally beat this thing to prove it can be done, and get him on top of it before he gets 'hooked'.

(BTW, the nurse asked him when he was getting glasses, he told her that he was going to do these eye exercises to correct the problem. She apparently got very angry and sat him down and said very sternly: "You can't change your eyes, you *neeed* glasses" it was pretty funny the way my son described it, with her hands doing a George Bush 'box sides' for emphasis.)

So i've basically got till September to get some serious results. I wonder if anyone has info or suggestions about someone who can do all the drills and can get good results, but can't quite get all the way to losing glasses forever. Is this common, or do most who work on this eventually succeed? are there any statistics that have been compiled? Also, i'd love to hear more about any psychological tendencies or suggestions about dealing with this aspect of the problem.

--End long intro--

Dear SI Lee, and hello all,

Sounds like you have a similar eye dysfunction to mine! I had crossed-eyes as a child, two operations on the muscles, and now (36 years old) my left eye turns out and up (such a joy...!). I have little to no central vision in the left eye although until recently the right eye was about 20/20 but has become a bit myopic of late. I see a double image to the right and slightly down of whatever I am looking at. I believe this is my left eye's peripheral vision. It took me years to finally realize (after reading Dr. Bates' book) that I was not looking directly at objects or people with my left eye. I was attempting to see with my peripheral vision. When I do look directly at an object, I make the object disappear; that's how I know I am looking right at it.

In recent years, my biggest accomplishment has been to learn how to "cross" my eyes and make them appear straight. Problem is that when I do, my right eye goes blurry and remember with no central vision in the left eye, I really do need that right one!

My ophthalmologist just prescribed glasses for my nearsightedness in the right eye and as protective eyewear. I will see an optometrist soon who does vision therapy and see if I can get my brain to accept that left central image. It is a fun challenge. What have I got to lose?!

If I add a page on the subject to my web site, I will let you know. I am looking to write a bit about the experiences of strabismics and welcome email. I am enjoying the email list much and am new. (Hope I post this properly.)

See you!

Hello all:

I am new to this list and would like to introduce myself. My name is Owen and I have been actively following a natural vision improvement program for the last two and a half years. During this time, I've been unable to find anyone in my area (optometrist or otherwise) who was even remotely interested in natural vision improvement so I've felt somewhat isolated. Luckily, I stumbled onto this group while playing with my computer at work. I would just like to relate my experiences and see if it correlates with anyone else's.

In addition, I have a few questions that I need help on.

Originally, I relied on a book I found by Janet Goodrich. Since then, I have acquired every book and piece of information that I could lay my hands on. I am very enthusiastic about natural vision improvement and am totally committed to improving my vision by this means. After years of hearing that my eyes would never improve but only get worse, this whole concept was fascinating. I can still remember how condemned I felt as a teenager when I was told that my myopia would get progressively worse until ultimately I would be a visual cripple, totally dependent on corrective lenses. So two and a half years ago, I began the quest to recapture my natural vision. The first thing I did was to go to the optometrist and get a baseline reading of my refractive error as well as a pair of reduced strength lenses. The doctor informed me that my right eye had degraded another 1/4 diopter since my previous visit (Ugh!) and my unaided vision was now -5.75 diopters Rt, -5.25 diopters Lf. I got a set of lenses: -5 Rt and -3.5 Lf with which I was able to read 20/20 Rt and 20/30 Lt. (Note: My actual Snellen chart vision in my left eye varies greatly from the objective retinoscope readings for some unknown reason).

My next step was to stop wearing lenses except to drive. My lens wear time was and is about 0 to 5 hours a week. I could do this because (being an engineer) my work is mostly at close range and my wife agreed to do most of the driving. However, at -5 diopters, anything more than 8 inches away was pretty blurry. But, my resolve was firm and nothing would ever get me back into dependency on lenses again. Even with the blur, the feeling of freedom was exhilarating. Every noontime (summer or winter), I would go for a two or three mile walk and let the sunshine (or snow) splash on my face. I would edge my vision around distant objects and shift my gaze from object to object. After a couple of months, the first thing I noticed was that the outline of objects was becoming well defined with my left eye. That is, roof lines on houses, street signs, fire hydrants etc. all had sharp clear edges with my left eye (the right eye was still blurry). I found I could even read license plates on parked cars with my left eye. I was very excited about this left eye development; but my right eye was "locked in" at -5.75 diopters and not responding at all. The first time I noticed my right eye improving was about one year later when standing in a lift line while skiing. As I was shifting my gaze over some letters on the side of the ski lift building, I noticed some of the letters coming in and out of focus. I closed my left eye and, sure enough, my right eye focus was pulling in and then fading out of focus. I couldn't keep it locked in but it would drift in and out. Since that time, I've been able to keep the right eye focused and it also can see the outline of objects with clarity. I can see roof-lines, chimneys, license plates and logos on approaching cars, billboards, streetsigns, etc. with amazing clarity (not 20/20) but very good. At -5.75 diopters, everything used to be a big blur (off the top of the Snellen Chart) when I removed my lenses; but now I revel in the clarity that I have - my noontime walks are the highlight of my day. The objects that I still have trouble with are those which have a lower contrast and more subtle outline. For instance, a roof-line against the sky would be high contrast, a person's face would be low contrast. If a friend is approaching me from a block away, his/her face does not have the same well defined clarity as the high contrast objects - but it much much better than .three years ago. In an office environment with fluorescent lighting, I also notice the same effect. That is, edges on high contrast objects are relatively sharp and clear (blackboards, wall panels, exit signs etc.). I also notice that my far point which started out at 6.84"Rt, 9.84"Lf appears to be moving out.

Note: At one time, I was using the far point method to gage my refractive error in diopters but I felt the accuracy wouldn't give me the resolution I wanted so I abandoned this method. (For example, at my initial refractive error of -5.75 diopters, a 1"error in far point reading would give an error of approx. 3/4

diopters. Also, my far point wasn't that well defined and I felt that a 1" error was too easy to make. Since I wasn't fortunate enough to experience the rapid, large changes in dioper strength I've read about in some case histories, I required a method which could measure subtle 1/4 diopter changes more accurately. I eventually obtained a series of minus lenses such that with various combinations, I could get diopter strengths in 1/4 diopter increments. These lenses, in conjunction with a Snellen chart, allowed me to measure any vision improvement by determining how many diopters were required to read the 20/15 line at the bottom of the chart. However, I seldom measure my vision this way anymore - I was beginning to talk like my optometrist "Which is better, this or this -- How about now?" Also, I felt that my analytical nature was somewhat inconsistent with the whole Vision Improvement philosophy.

My vision improvement experience has been totally awesome (Oh no, I'm starting to talk like my kids). However, there are some things I am still pondering:

1. When I measure my visual acuity (using the 20/15 line on the Snellen chart and an assortment of lens combinations) in a florescent light environment, it appears that my eyes have improved by about 1 1/2 diopters. When I perform the same test outside, even on an overcast, dreary day, the refractive error is much less. In fact, I can read the 20/50 line (and sometimes better) with no lenses. Why the large discrepancy? Has it something to do with the spectral content of the light? I plan on obtaining a full spectrum light and experimenting.
2. About a year ago, I read of an instrument designed by an optometrist in New York (Dr. Trachtman) called an Accommotrac which provided biofeedback for the involuntary focusing muscle (ciliary muscle) within the eye. I read a number of successful case histories which prompted me to go to the local university and research the details of this device. As a result, I understand the principles quite well and was even considering building one myself.. I certainly had no intention of infringing on Dr. Trachtman's patent but only wanted to experiment with this device and had no access to one. I begged, borrowed, and purchased all the materials I needed to build a rough, but hopefully workable prototype - about \$300) , and had a machinist friend fabricate the necessary mechanical pieces. Just as I was about to embark on this project, a behavioral optometrist told me that he had read several studies which indicated that the instrument was not as effective as advertised; and that many of these devices were showing up on the used instrument market at bargain basement prices (\$2000-\$3000). My feeling is that the effectiveness of the device is a huge function of the motivation of

the user . If one expects a painless, effortless improvement just by sitting in front of an instrument a couple hours a week, then the instrument is likely to be ineffective. However, if used in conjunction with other vision improvement techniques, it seems it could be a useful contributor to one's vision improvement efforts. Has anyone had any direct experience with this device and, if so, what do you think? Am I being over analytical?

I have recently found an excellent behavioral optometrist whom I plan on seeing in the near future. I also am planning to get full spectrum lighting for my office, and am starting to get a feel for some of the psychological, imagery aspects of natural vision . This has been the hardest part for me, but I'm slowly but surely warming up to it. I'm also experimenting with expanding my peripheral vision. I find Dr. Kaplan's two books "Seeing Without Glasses" and "The Power Behind Your Eyes" to be a great inspiration.

That's all for now.

Regards ,

Owen

Hi Elena, all I_see-ers, and greetings to the newcomers (GREAT posts!),

I entirely agree with your totality approach to myopia. Myopia has to be understood from within and the battle on the psychological front when we are adults seems to be the key one. Not so, though, in childhood years when proper visual habits are more important, in my opinion. (to the extent that incorrect visual habits are not caused by psychological predisposition). But who was to tell me that when I was 10 - neither parents, nor teachers, least ODs who viewed (and continue mostly to view) myopia as a predetermined course from which there is no escape. Oh, ignorance!!

>I realized

>that striking parallels exist between the way I see and the way I think

Agree, same with me, although, it's kind of a mix of thoughts and feelings as they generate each other. In this line, I've been told by several people over the past several months, that they feel more confident of the way they see if they have a clear plan and dedication of their lives, besides improving vision, so that vision health is something of a by-product, be it a very important one. One of Linda Lee's last posts was to this effect which I attacked somewhat and will be sorry if her prolonged silence has been caused by my strong words. I remember, in my wild late teens, when I was wearing contacts (soft) for about three years, I used to do a lot of close work in them at school or university. I would always take them off at home, but outside I might spend hours in a library, or half a day of classes. Even that long ago I used to closely watch my acuity, every night that I made it home for dinner I would look at a calendar on the wall across from the dining table (contacts still in) and would check how I see the numbers. Luckily, during this three year period my vision remained stable, despite heavy near work load. Was this a contacts effect (vs spectacles)? Even if there was some (many discussions exists on this topic), I can't wear

contacts now, even if I was able to tolerate them. What has happened? It's a change of thinking. Like Elena I have grown almost allergic to minus lenses of any kind, or to put it more precisely, to any kind of lens that gives me more acuity than I need for a *prolonged* visual task (the ciliary is there to take care of the short ones, after all).

>In the meantime, here's an update of my progress.

>

>1. Daily spontaneous clear and "semi-clear" flashes that last up to a few
>hours. The best acuity experienced in a spontaneous clear flash 20/20; the
>longest duration of uninterrupted 20/20 vision -- about 5 minutes in a row;
>20/40 -- about 30 minutes; with constant interruptions, "on and off," 20/60
>- 20/80 typically lasts all day. (Compare to approx. 20/1000 a year ago.)
>During "interruptions," vision fluctuates widely, sometimes getting nearly
>as bad as the initial pre-VT figures but never getting "stuck" there.

Congrats! However, this relapse to near pre-VT acuity is puzzling. I'd hypothesize that it is most likely due to an accommodative spasm. In any case, no matter how much you dislike it, I think a comparison of axial lengths would shed a lot of light on the process. So far I haven't been able to locate any OD or MD who can take my axial lengths (I think this is done by ultrasonography). Corneal topography measurement seems more widespread, especially now with the advent of PRK. After all, our multifaceted approaches will have to cause some physiological change. You can liken it to losing weight, no matter how "metaphysically" you deal with it, you want, when you step on the scales, to see less weight.

>5. What, far as my present understanding is concerned, WON'T work or at
>least won't have lasting effects: hypnosis, NLP, psychoanalysis, any form
>of traditional psychotherapy --

Agree entirely.

>Vision is not behavior. It has nothing to do with how you
>behave as an adult. It has everything to do with how you FELT INSIDE as a
>kid -- or even as an infant.

In any case, exploration of how one felt in early childhood won't hurt. In searching to recreate the genesis of my myopia I have recalled a myriad of scenes from ages 6 and up. Crucial, since NO ONE in my entire family tree is myopic, I am the first one. Basically, what it boils down to is excessive close work, the simple solution to a complex problem. I can recollect long hours studying Egyptian history, a teacher encouraging me to wear glasses despite my reluctance, self testing for acuity by holding a newspaper at arms length and still being able to see it (that comforted me when I was -1.25 D), going to school during the summer and writing words on the blackboard and then testing myself from various distances so that I know where to sit when school starts in September, and many, many other bits and pieces. Again, I think I know the answer - excessive near work caused my myopia plus

my ignorance (and I should add my parents', teachers' and ODs') to counteract it when the chances for success were much higher. Now it's certainly more difficult and I am still unsure if there is some limit to improvement or one can reasonably hope to regain 20/20 no matter how bad their vision is. But at least we can take good care of our children.

Regards,

Stefan Stefanov

just to add a note... after reading about Elena's progress, i looked back through my journals to when i'd made the huge jump in improving my vision, (7/94 - 11/94) and ...guess what... i was doing yoga that whole summer! i had been recovering from knee surgery due to an injury from dance (i was studying with a company at the time) and yoga was the ONLY thing i could really do.... even swimming was out of the question. Of course, when i was strong enough, i went back to dance classes. and this nearly corresponds to the time the improvement plateaued!!!

however, i also have had a lot of weird emotional flashbacks during this past year and a half, which may or may not be related. she does allude to the contribution of the emotional self in her post.

Anyway, i have recently been checked and though i have not improved any, i am very thankful to note that despite a tremendously loose eye exercise routine, i have lost NONE of my improvement. I'm gonna start doing yoga again and see what happens. I'll keep ya posted.

eileen

-

Hi Everyone:

This is my first post on the I_SEE mailing list. My name is Varun Verma, and I am an Electrical Engineer by profession. I started my vision programme about 11 months ago (last August). I have been following this list since but have not been posting my own progress and programme.

When I started, my eyes were -3.5 (L) and -4.25 (R). Now they stand at about -1.5 and -2.25D respectively. I started with Bates' book and other "vision without glasses" books. But they did not help me much and I realized (in striking parallel to Elena's approach) that my vision is a product of my own attitudes and thoughts. My article in sci.med.vision "My 10 point program to improve vision" has been long forgotten and I stopped posting any more articles. And now I felt like writing more.

I rejected western concept of myopia (I am from India) and turned towards eastern concept of self-healing (deep rooted in ancient Hindu tradition -- also the source of Yoga). I learnt that I and my organs (including my eyes) are a product my own awareness and so first action is to break into my current mind-set and myopic habits. I realized I have to be a different person if I have to overcome my myopia. And this combined with my own daily drill of relaxing my eyes and training myself to look into distance with faith and aplomb has given me best results. The ideas are abstract but powerful (and parallel to Elena's). It involves a lot of self-realization and has spiritual aspect. It gives me more control over my vision and ability to generate clear flashes at will (including in nights).

I would like to share a lot of ideas with Elena not only because she is the most successful but also her approach is similar (if not same) to mine.

Thanks and all the best:
Varun

>tradition -- also the source of Yoga). I learnt that I and my organs
>(including my eyes) are a product my own awareness and so first action
>is to break into my current mind-set and myopic habits. I realized I
>have to be a different person if I have to overcome my myopia. And

I couldn't help noticing this comment. I feel the same way to an extent (words being imprecise). I've worked on disrupting the routines of my thinking and acting somewhat, though not as mindfully and as thoroughly as I would like. I have found this to help a great deal in increasing overall fluidity. Taking off glasses is one way to do it which I have been doing more and more lately. Occasionally, I drive for a while without glasses (-9/-8). It's not as exhilarating as I would like, but it is relaxing and I frequently put my glasses back on when things get fast or chaotic. I've also found that I have a growing sense of recovering my original purpose.

-

I had a great visit to an optometrist Saturday and discovered I have a .75 diopter improvement in each eye (stats below). Dr. Larry Smith was puzzled, but sympathetic and open to the possibilities of vision improvement. Apparently, this was the first time he had seen an improvement in his what looked to be about 50 years.

I had taken my glasses off for most of the morning prior to the appointment, and I had spent a few minutes with the Chinese facial energy point massage techniques. This helped counteract the effects of staying out too late in unwholesome environments the night before.

At first, one of the assistants used a machine to test my accuity, apparently with lasers. It had a picture of a multi-colored balloon against a blue sky. The picture would periodically move in and out of focus. I asked her how it worked, but she didn't know. Then I had a glaucoma check. She then took me into the optometrist's office. During this time I did not wear my glasses except when I was walking to an area of the building I had not seen yet. Initially, I felt some trepidation about not wearing glasses and thus calling attention to myself in a strange setting, but I go over it.

I got tested for 20/40 lenses and discovered that, when Dr. Smith tried some lenses in that range, if I relaxed and intended to focus for a micro-second before answering which was better (one or two?), the letters would become crystal clear. Based on that observation, I decided to

get the lenses of one diopter less than my 20/20 prescription.

While behind the lense apparatus, I blinked a lot and closed my eyes alot.

Perhaps pivotal to the visit was an energy shift just prior to walking into the optometrist's office. I had been very non-committal and had been mentally preparing for an argument. As I walked to the office, though, a feeling to exhuberant, relaxed confidence came over me and my worries vanished.

I look forward to greater improvement. Now why is it that I'm willing to perform under pressure, but when there's no pressure, I get a bit lazy?

Here are some measurements.

Brief history: glasses at 6 for myopia

Date	Age	Prescription	Circumstances
7/14/86	22	O.D. -9.00 sph., -1.75 cyl., 020 ax. O.S. -11.25 sph., -1.00 cyl, 025 ax.	summer after undergraduate
4/7/88	24	O.D. -10.75 sph, +1.75 cyl., 105 ax. O.S. -11.25 sph., +0.75 cyl., 100 ax.	in middle of graduate school
12/14/92	28	R -8.75 sph., -1.25 cyl., 12 ax. L -9.75 sph., -75 cyl., 03 ax.	working in computers, some yoga and meditation
6/22/96	32	O.D. -8.00 sph., -1.00 cyl., 10 ax., 29 PD O.S. -9.00 sph., -0.50 cyl., 10 ax., 30 PD	working in computers, palming, sunning, tai chi, etc.

Later this week, when the new lenses are ready, I'll be wearing

R -7.00, etc.
L -8.00, etc.

Hi Paul:

I wrote that article in the beginning stages. I will have to dig it out (if I saved it at all). Since then my method has evolved to become more holistic involving not only physical exercises and relaxation but also fixing one's spiritual awareness and drawing strength from Self.

Varun

Stefan,

Recently you wrote:

>Agree, same with me, although, it's kind of a mix of thoughts and feelings as they generate each other. In this line, I've been told by several people over the past several months, that they feel more confident of the way they see if they have a clear plan and dedication of their lives, besides improving vision, so that vision health is something of a by-product, be it a very important one. One of Linda Lee's last posts was to this effect which I attacked somewhat and will be sorry if her prolonged silence has been caused by my strong words.<

. . . and it is so lovely to be missed . . .

Actually, i have been very noisy lately, just haven't had much time to keep up my correspondence on the I_see board. Our local theatre group has recently honoured me by staging a play i wrote and i have been busy editing, re-writing and generally hanging about with actors and such. It's something of a new direction for me and i can't tell you how much i am enjoying it.

Although i achieved early results with VT, I reached a plateau some years ago. I decided that since what i was doing wasn't working, i would try something else. Now i am making the effort to express myself more directly through writing and performing.

I remember when i had my first flash of clear vision, my immediate thought was "i don't deserve this". I hope to be able to turn this thinking around and learn that i do have something to say, and that i do have value. And that i do deserve to see how beautiful the world is. By setting my sights on, and reaching distant goals, i hope to convince myself of this.

I'm having some minor success as a local hero, and it's fun. People look at me oddly, saying -" i had no idea you could do that! How do you write like that?"

Dunno. I just can. I thought everybody could.

So i'm using the time i used to spend reading about VT, meditating, and writing in my journal about vision, to learn about playwrighting. And writing, and going to drama festivals, and singing. And dreaming bigger dreams. And making them real.

I don't know if my vision is getting better or not. For the moment, i'm not thinking about it much. I am feeling better about myself lately. Much better. In the end, i don't think it matters much how to choose to get up the mountain - just pick a path and stick to it.

Still, i keep reading the postings on I_see. I too am delighted that new people have joined and are contributing.

Stefan, don't worry for a moment that your words have kept me quiet.

As if anyone could!

Linda Lee

I too have been playing with my floaters lately while lazing on the beach. I've observed that the floaters are more annoying when I deliberately look at them in a nearsighted way. When I adopt a farsighted posture, that is looking beyond them, the floaters don't bother me.

I believe this may also have been reported in the book on Yoga and Eyesight from India. I love my floaters. It is like watching an intergalactic fireworks show.

Enjoy the sun. Nice progress report Elena. I agree with much you report. BTW If you have not read the book The Infinite Mind by Valerie Hunt. DO.

Hi Mark:

For those techniques, you have to break from western materialistic concept which creates desires for the impermanent and makes one forget/unaware of the immense inner strength of the spiritual Self. We always look outwards in this materialistic world for everything which does not fulfill our desires except filling us with more. We feel helpless and craving all the times and there is no end to it. The aim of the "Yogi" is to generate his happiness and satisfaction from the absolute Self and not relative to the outside world. This is first step towards self-realization. Glasses are an external dependency which is definitely an insult to the natural intelligence and strength of the eyes.

This concept of Self does not mean being self-centered but creates a new view in which people draw their happiness from self and are in harmony with rest of the universe rather than being at war with it through various materialistic pursuits.

These techniques treat eye disorders more holistically than localized.

Believe me you cannot be the same person and still cure your myopia. Ask Elena if you do not believe. Am I right, Elena ?? It might sound too vague and abstract.

Hope it helps:

You are describing an **autorefractor**. I am inserting part of a message I sent today to another person.

>I've never used nor seen an autorefractor, though I saw pictures of
>them on the Web! What do they cost used? Do you own one now?

The autorefractor is a very clever device. It's compact, **very** easy to operate (you still need **another** person to measure your eyes), and in my experience, very reliable. ODs seldom perform autorefraction themselves, this is handled by their assistants as this is a very easy task (that's why it is an **auto**refractor). Some assistants will say that autorefractor measurements are not very reliable but, again, I think this is purely a marketing trick to make you sit with the OD for the "one or two" thing. I have had close to 40 (forty) autorefractive measurements and I have found all of them to be very accurate, especially if one sticks with a specific autorefractor make. Surprisingly to me, autorefractors are not common in the US, as opposed to Europe. I used to just walk in and **only** have my eyes autorefracted by an assistant for about \$2 a go.

As to pricing, autorefractors are fairly costly, I would say in the order of

several thousand dollars. I don't own one but there was this interesting discussion on s.m.v. 4-5 months ago about autorefractors becoming a handheld consumer device. I dream for these days to come. Major manufacturers: Humphrey (of Carl Zeiss GmbH), Rodenstock, Nikon, Topcon.

This is somewhat off topic but I thought it could be useful to any who haven't heard of the autorefractor. I have some guesses how it works but am not an expert and wouldn't want to give you patchy info. I think there are some technical people on the list who may offer more.

Varun,

thanks for sharing your views and experiences and noticing the way they parallel mine. I should note however that Mark is much more of an expert in Eastern approaches than myself.

I cringe at the thought that what's recently happened to my "philosophy" is that some of Russia's historic fate -- to be between East and West and neither -- has finally caught up with me -:). I do think that some Oriental traditions that view human mind/body/spirit as a unity are right on, while much of Western science has misplaced its Occum's razor or something and is busy catching smaller and smaller fleas of knowledge -- but still powerless to assemble them into as much as a worm, let alone a healthy and happy human being. At the same time, the "metaphysical" part of my thinking has plummeted to a record low. The "Real Self" is something I'm very much concerned about (in particular, my personal "real self" has perfect sight, that much I remember), but I'm not sure it's something to look for any further than beyond all the distortions superimposed by unnatural and inherently cruel methods and circumstances of upbringing, quite universal for East and West alike. I'll try to elaborate when I have the time.

To correct some of the outcome of this distortion, yoga does seem to work great. And yes, when a change takes place it's a holistic change, and it's anything but minor.

Hello Nick,

I am a patient undergoing PCM (Precise Corneal Molding), a form of Ortho-K. I seem to be the only patient on this list that is or has used this form of eye correction. PCM is non-surgical, and uses molds to reshape your cornea. The molds are just like hard contact lenses, and I think are more comfortable. IMHO, PCM is perfectly suited for astigmatism. My astigmatism was gone in a week. I don't recall how bad it was. I am currently working on reducing my -1.0d to zero or thereabouts. I have been under going treatment for 1.5 years. I started at -5.0d.

Sincerely,
Rob

Hello all -

My stats: Just about 40 years old (July 23rd), wearing glasses for nearsightedness since 7th grade progressively getting worse over time. Current prescription is -3.25L -2.75R. Slightly astigmatic.

I have gone back and read all of the archived messages and learned a GREAT deal of info. For those of you who have web access, I STRONGLY suggest you spend the time to do this. A tremendous learning opportunity awaits you.

One thing I found very interesting was the use of + diopter reading glasses for myopia. I bought +1.25 glasses at a local drugstore and have been using them now since the afternoon of July 4th (how appropriate - the beginning of my INDEPENDENCE from glasses!). Well, by nightfall I noticed a difference in how I was seeing without my glasses. So, I continued using the reading glasses whenever I could for reading, walking around, etc.

Yesterday, I actually drove my car for about 10 minutes without corrective lenses at all! Yes, it was in bright daylight, but I had very frequent clear flashes as I drove. I was able to read many of the license plates that were in front of me and those that passed me. I have worn my regular glasses maybe 3 or 4 times for brief periods over the last four days. Also, I have sunned and palmed at every opportunity as well.

As I write this, I am not wearing glasses at all. Probably the first time since the 7th grade that I am able not just to function, but actually see clearly enough not to need these spectacles! Absolutely amazing to me!

At first, I thought the clearness of my vision was one of those passing things. But, it has continued and has been consistent for the last four days. I am using the reading glasses at every possible opportunity and am noticing an improvement in some aspect of my vision each and every time.

Question: What do I do now? When do I up the diopter number on my reading glasses? I have been slowly moving my reading stuff further away as I read. Improvement there, too. Will a higher + number speed up the process?

Some of the archived messages dealt with the mental/spiritual side of myopia. Elana (I believe that's who it was) related her experiences with her high myopia and the mental and emotional implications of it. I believe one reason why I can see the way I do now is my unwavering believe that this is the right thing to do and that my glasses were nothing more than a crutch and will do more harm than good. So, what do you do? Get rid of the harmful item and more toward a more beneficial way of seeing and living. So far, so good!

Thank you to all who have posted here. You have done a world of good for my eyes. Keep it up!

- Larry

Probably not 3 D if it was gone in a week :)

I just finished talking with a behavioral optometrist on the phone. She told me that although they have good luck with reducing nearsightedness, with 3 D of astigmatism they would probably just correct it. I have been looking around, and while there seems to be pretty good evidence that myopia can be decreased by plus lenses, and perhaps small amounts of astigmatism can be corrected with lenses etc., it seems that large amounts of astigmatism probably can't. The accommodation errors in nearsightedness are pretty different from ellipsoidal eyeballs in astigmatism.

Here are a few hopeful factoids about astigmatism.

The first is, it is possible to see clearly and still have astigmatism. There seems to be a type of astigmatism present among Asians and American Indians, so I hear, such that, even though the "objective" measurements say "astigmatism", the people with this "defect" see clearly.

The second is, the REASON why behavioral optometrists don't think they can cure astigmatism is because they are trained to believe that any "willed" change in the refractive status in the eye must be due to the ciliary muscle on the lens, whereas most astigmatism shows up clearly on the cornea. In other words, it is heresy to propose that the OUTER ("extrinsic" / "extraocular") muscles have anything to do with any refractive error. However, the extraocular muscles are precisely those anatomically in a position to change the shape of the cornea.

A curious heretical article on the topic of changes in corneal astigmatism was published in the 1930's in the Review of Optometry. Check the I SEE library

http://ezinfo.ucs.indiana.edu/~aeulenbe/i_see/library.html

under "optics" -- The Incredible Changing cornea. Optometrist C.W. Parker had success in treating mild cases of astigmatism with eye muscle exercises, and he also observed a rapid change of astigmatism in a woman who had undergone extraocular muscle surgery.

My opinion is that behavioral optometrists have not had success correcting high astigmatism BECAUSE they have assumed it is a hopeless case.

Having said that, I recognize that high astigmatism is often noticed at an early age (unlike myopia which surfaces usually in the teens), and can run in families. If astigmatism is hereditary in these cases, my guess is that there are certain muscle patterns that are inherited, much like the universal "sucking reflex" -- there may be some people born with an "astigmatic reflex" that nonetheless can be unlearned. Of course, if kept up through life, this "reflex" may be hard to undo, but not necessarily impossible.

--Alex

Greetings from a holistic (behavioural optometrist)downunder,

Regarding astigmatism:

A patient of mine experienced floating on the ceiling watching his own open heart surgery. From where was he seeing; who was doing the seeing and what did his eyeballs have to do with it? We do not see WITH our eyes. When I examined my good friend Jacob Liberman in November 1994 I still measured the 2.50 dioptres of astigmatism in each eye. In spite of this he demonstrated 20/20 without any glasses. Vision is the relationship between insight and eyesight. It is not bounded by the body.

Regards,

Peter

I live in southeast Florida. I know you didn't ask me, but my numbers were -5.75 back in February and I sometimes drive without correction as well and thought you ought to know!

I have trouble reading tag numbers, but not seeing cars and such. I find my depth perception improves without lenses. I have my clearest flashes while driving.

I'm new to this list and have only been trying to improve my vision for a couple of weeks now. I've been palming and sunning. My far point is about 19 cm so I don't think that reading glasses are necessary yet. I have to get that close to the computer screen which is bad enough as it is. I've tried this before but haven't until now been able to live comfortably with the blur. I've noticed an improvement in depth perception as well and my glasses give me a headache now. I don't like working this close to the monitor but my eyes feel better.

Any suggestions? What program worked for you? I am inspired by Mary and I would be interested in what your far point is now and what did you do to get there?

Thanks,

Frank

Hummmm. Far point. I am guessing you mean how far away can I see really clearly without lenses. Let me run get a measuring stick. . .

It is about 11 - 15 inches (sorry, I can't seem to find ANYthing with metrics on it right now) with the naked eye. That is, I can now read the morning paper even if I don't have my usual contact lenses in. When I started, it was about 4 inches (yes, I mean it). I consider that alone a great triumph.

What do I do? Well. . . even though I don't NEED them when I am wearing a reduced prescription contact lenses (I buy disposables, so I can change the power regularly) - I wear plus lenses WHENEVER I use the computer or read within arms reach. I am currently using +2.00 "reading glasses" over -3.50 disposables. I tossed the last pair of -3.75's last week. It sort of amounts to wearing -1.50's to read, I guess, instead of the transitional -3.50, or even worse, the "full correction" -5.75's.

I think sunning is important, so I read the newspaper outside everyday. I spend somedays lenseless (with a back-up pair of glasses, if I need them) and that is when I drive. If I need to read something, I usually just get closer, on those days. I also eat well. I was using "Eye-bright" capsules, but now only use the homeopathic Eurphrasia Officinalis dose, when I need it, for tired, red eyes. I also used Bilberry capsules for a time. I make sure I get enough salt, etc. And I laugh a lot.

My subjective view is that I see as clearly now with -3.50 correction as I did last December with -4.00 lenses. I had before that been wearing -4.25's for about 5 years. I don't think I have ever minded the blur as much as the eye docs have. . .

I think you can get a day-only driver's license if your vision can be corrected to 20/70. And people can improve there visual acuity by squinting.

But your way of expressing yourself was very harsh. Let's keep flames off this list.

I would like to point out to people driving with low visual acuity, though, that it's possible to drive without crashing on familiar streets and still not have it be safe. It might feel safe but the point of having good vision to drive is that unexpected things might happen -- kids running in your peripheral vision, etc. So don't overestimate the safety of driving just because you've driven that way without having problems. 20/40 for general driving and 20/70 for day-only driving seems like a good limit to me. Actually 20/70 is pretty generous because you can't see signs far off with 20/70 vision and it's easy to get into an accident because of not seeing them far enough ahead of time.

In a vaguely related vein:

A police officer stopped a young woman after she made a one fingered gesture in his direction. He ticketed her for failing to wear the corrective lenses indicated on her license. When it came to court, however, the judge declared the stop unwarranted and threw out the charge.

Happy trails. . .

I don't have any scientific evidence, but I do know that MY body works better with a bit of salt. I eat relatively little processed food now, and don't have to worry about getting enough potassium, through the foods I do eat. Maybe I am balancing my electrolytes?

During both my pregnancies I would get heartburn if I didn't keep my salt intake up. I would often use a tsp. of baking soda in water before retiring, to avoid acid reflux. I never experienced any swelling of extremities (hands, feet, ankles) that the OB's all warn of. It seems that blood volume is greatly increased then, and perhaps that requires more salinity.

I have recently read of a study that links CFS with a "malfunction" in blood pressure regulation. Part of the suggested "cure" (that apparently worked), was to up the intake of table salt. Do you think the appearance of this new malady might be a result of folks reducing their dietary sodium on the advice of the medical establishment? Did you know that only 11% of those with high blood pressure are sodium sensitive?

I don't suffer from CFS, but my blood pressure readings are low - 118/72, even with my children arguing in the cramped examination room. During pregnancy, the numbers were even lower. So maybe my "malfunctioning" old self just needs to self-medicate. I know it makes a difference in how well I see and feel.

I agree that it is much safer driving in familiar territory when lenseless - I limit myself to places I know. And there is a great difference in how well I see on a sunny day vs. a rainy, cloudy one. And night vision is another thing entirely.

I also know that no one else can judge how well I see from my "full correction" eye exam numbers. Just as light and weather conditions fluctuate, so does my visual acuity. I guess we could legislate the amount of sleep one is required to have, and what kind of breakfast one must consume, before taking the wheel. . .

As startling as it may seem, there are many things we can have no control over. The only limited control I can count on is myself, and not even that every moment. Once I came to terms with that, I realized things are going along pretty nicely anyway.

I almost forgot - I have been working on my peripheral vision by learning to juggle. I look through the airspace, not using my central, focused, vision at all. But then I have always been able to see things that move, and was an excellent shot (targets, not animals) without lenses.

There is more to seeing than reading letters at a distance.

I don't know about CFS specifically, but misguided dietary guidelines dominate the scene so pervasively that I wouldn't be surprised if this were the case. I've read about a number of deficiencies (ranging from mild to deadly) that may accompany the routinely recommended reduction of salt intake.

My own hearty eating habits, combined with the fact that I haven't gained an ounce in twenty years, have shocked many a dieting dining companion, although they are exceedingly simple -- I eat what I like, when I like, as much as I like, and trust my firm mental resolution to maintain my body's "best" weight to take care of the rest. As a side effect of this truly all-natural approach, my palate automatically responds to artificial, overprocessed, etc., "foods" with immediate judgments like "incredibly yacky" or "outright inedible," so I don't have to exercise any willpower to avoid them. I remember taking, seven years ago, my first sip of a "diet" drink with nutrasweet, for instance. I spit it out and screamed, there's something awful in this soda, it must've been tampered with, I think it's poisoned! No kidding!)

What I would like to figure out though is what eating patterns may affect vision directly. My personal "eating style" had changed dramatically simultaneously with the development of myopia at 13, with probably a 500% increase in carbohydrate intake and overall appetite.

I think salt must have something (a lot?) to do with the structure and function of as aqueous an organ as the eye -- any specific info, anyone?

Elena

What I would like to figure out though is, to what extent

Did you know that only

>[...] I feel he is being irresponsible.

I wouldnt recommend driving without clear vision, but i do it frequently myself. On days when i have been going a few hours without glasses on and it's sunny, and i'm not stressed, i can perform quite safely behind the wheel. At these times i can read any license plate up to 50 feet and any road sign. The trick is that i dont try and push it or force myself to survive the drive, the moment i feel any anxiety from not seeing adequately, i put on my specs, since stress, after all, is the enemy.

Driving without glasses is a very relaxing, so i will definately continue. I believe that i see *\*more\** at these times though not as clearly. My peripheral vision is much more active, and my mental component of seeing is more tuned in.

Better that than the wife who sued her husband for not being well  
endowed. She took him to small claims court. The judge threw it  
out due to lack of evidence!

Happier trails...

If you can see license plates 50 feet ahead your visual acuity is probably fine.

What bothers me is people with 3 D or more of nearsightedness driving without glasses. Such people are probably legally blind, having 20/200 distance vision or worse.

If they were the only people on the road, or if everything on the road were predictable, it might not be a problem. But, there are children around. Also, bicyclists depend a lot on drivers having clear vision. A bicycle is smaller than a car and doesn't move with the cars. I would really hate to think of a legally blind person driving, not seeing a bicyclist until 20 feet that someone with 20/20 vision would see at 200 feet, and hitting them. Or, a legally blind driver looking at a car pointed towards them, thinking it's parked, when it's actually coming towards them.

If a person isn't legal to drive without glasses and they injure or kill someone they could easily be sued and perhaps prosecuted for reckless driving or involuntary manslaughter.

It seems to me it's best to leave the experimenting with vision for times you know you won't hurt someone if your vision isn't good, and play it safe while driving and wear some correction that gets you to 20/40 at least. If you can pass the DMV's eye test, fine. But if not, it would be safer for those around you to wear the correction. The DMV's rules about vision acuity are there for a reason,

and I don't think they're overly strict.

>I don't have any scientific evidence, but I do know that MY body works  
>better with a bit of salt. I eat relatively little processed food now,  
>and don't have to worry about getting enough potassium, through the foods  
>I do eat. Maybe I am balancing my electrolytes?

This is so bizarre...

ONE DAY before I read the original letter, it dawned on me that I had started feeling better in general (a few days' worth of it) since my salt intake increased. Less eyestrain, less gastric discomfort (digestion is touchy). This puzzled me since I've been as inundated as anyone with the dangers of a high-salt diet, though I don't avoid salt specifically. I analyzed my diet and realized that I was eating *\*very\** basic foods (Fast food is WAY too expensive!) and not seasoning them much. In the past week I've gone on a cooking kick which has included saltier-than-normal foods, although I suspect commercial stuff is saltier still! I'm going to keep experimenting with this.

# Re: Salt

---

- *Subject:* Re: Salt
  - *From:* Betty Martini <[betty@noel.pd.org](mailto:betty@noel.pd.org)>
  - *Date:* Sat, 13 Jul 1996 11:08:22 -0400 (EDT)
- 

Dear Elena: This isn't just about salt but the mention of chronic fatigue syndrome and hypertension, and dietary patterns. Sometime ago there was an almost 2 page article in our local newspaper, Atlanta Journal Constitution called THE ENEMY WITHIN and it was about chronic fatigue syndrome. One question asked was: "Could it be something in food?" It went on to say that chronic fatigue syndrome only surfaced in the mid 80's.

Even the Ebstein-Barr Association changed their name to Chronic Fatigue And Immunologic assoc - some name like that - and I believe in about 1990. They are not the same. Dr. H. J. Roberts explains that aspartame breaks down the immune system and triggers chronic fatigue syndrome - big time! Indeed, in an article by that Association gives several foods not to eat and includes aspartame. I think I may have the article on email and if so will put it on this network.

When diet drinks cooked in the Arabian sun of 120 degrees in the Persian Gulf aspartame liberated methanol in the can at 86 degrees. They stayed on pallets for as long as 8 weeks and they drank them all day. This is why Desert Storm Syndrome victims suffer chronic fatigue syndrome.

Aspartame causes the hypertension. In Dr. Roberts book ASPARTAME (NUTRASWEET) IS IT SAFE? ON PAGE 166 it says:

"Thirty-four aspartame reactors without previously-known hypertension were found to have an elevated blood pressure - systolic, diastolic, or both (It may have contributed to the concomitant headache in some). In the majority, the blood pressure promptly returned to normal after stopping aspartame products. Similarly, Shabin and Albert (1988) indicated that patients with hypertension appear more prone to the adverse effects of aspartame. "

On page 167 it says:

"A number of mechanisms could be involved in inducing high blood pressure in aspartame reactors. A few are mentioned briefly,

\* Aspartame may elevate blood pressure by increased norepinephrine, epinephrine and dopamine within the nervous system. All are derived from phenylalanine, its major component.

\*Some patients who consume considerable aspartame products seem to develop a craving for salt (sodium chloride)...as well as for sugar, sweets and caffeine (colas). In conjunction with their greater thirst (chapter 21), an increased intake of sodium could contribute to a rise in blood pressure (and fluid retention).

\*Previously effective antihypertensive medication (as methyldopa or Aldomet) became ineffective in several patients, possibly because of apparent drug interactions with aspartame."

Of course, aspartame is a drug and not a food additive. And as to vision problems aspartame causes so many, from black spots, floaters, flashes, blurred vision, retinal detachments and blindness. It just simply destroys the optic nerve because methanol converts to formaldehyde and formic acid in the retina of the eye. In one study someone was actually bleeding from the eyes (Walton), conjunctival bleeding.

Thought you would find this interesting since you were on the subject of CFS and salt.

Regards,  
Betty

Methyl alcohol is very toxic to the fetus causing malformation and even death.

Immune system damage occurs through exposure to methyl alcohol and its effect on the thymus gland.

Other organs affected include:

Brain and central nervous system

Heart and lungs

The "NutraSweet hangover" consists of: malaise, nausea, headache, dizziness, visual disturbances, and even convulsions. This occurs because of methyl alcohol in cigarettes, alcoholic and NutraSweet containing beverages.

Signs/symptoms of Multiple Sclerosis (MS) and other demyelinating disease (ie ALS) are similar to methyl alcohol poisoning.

Suspect methyl alcohol intoxication in:

- |                         |                                  |
|-------------------------|----------------------------------|
| (1) Recurrent headaches | (6) Birth defects                |
| (2) Mental aberrations  | (7) Childhood CNS illness        |
| (3) Seizures            | (8) Urinary bladder disturbances |
| (4) Suicidal tendencies | (9) Skin lesions                 |
| (5) Behavior disorders  |                                  |

More extensive, and unbiased testing must be done to determine the safety of NutraSweet!

Because of the damage done to the brain and other organs by the end products of methyl alcohol intake, the only way to avoid these deadly side effects is by AVOIDING THIS LETHAL SUBSTANCE!

# Effect of Salt on Myopia

---

- *Subject:* Effect of Salt on Myopia
  - *From:* Alex Eulenberg <[aeulenbe@indiana.edu](mailto:aeulenbe@indiana.edu)>
  - *Date:* Sat, 13 Jul 1996 11:20:41 -0500 (EST)
- 

The topic of salt and its apparent anti-myopic effects has come up again. As far as I know, the only published material dealing with the effect of salt on myopia is that by Emanuel M. Josephson, MD, a renegade physician who published in the thirties and forties. He found that an increase of intake of table salt can lessen myopia. His theory was that myopia was caused by a salt-water imbalance in the body. Note, however, that his cure was not "eat salt and see" but rather, he advocated eating well, in general. He put particular emphasis on vitamins, fat, and salt. As Mary, Tara, and Elena have have been saying, conventional wisdom regarding "good" versus "bad" foods is not always the absolute truth.

For more on Josephson's "salt-water imbalance" theory of myopia, see

[http://ezinfo.ucs.indiana.edu/~aeulenbe/i\\_see/josephson.html](http://ezinfo.ucs.indiana.edu/~aeulenbe/i_see/josephson.html)

>I guess we could legislate the  
>amount of sleep one is required to have, and what kind of breakfast one  
>must consume, before taking the wheel. . .

And while we're at it let's regulate the amount of perfume and deodorant one is allowed to use -- some people are allergic and may be harmed by others' irresponsible overindulgence. And the volume of dandruff a citizen is allowed to shed -- environmental pollution is rampant!

As for driving -- this is serious -- I would absolutely prohibit, eliminate, legislate out of existence

- a)stupid drivers;
- b)those with an ungratified and overactive killer instinct;
- c)those who are suicidal;
- d)workaholics who share their attention between the road and a laptop computer;
- e)cellular phone users;
- f)human dinosaurs whose CNS gets messages about the color of the street light apparently via the spinal cord, with a 2 1/2 minute delay;
- g)medical residents trying to get home after a 36-hour shift;
- h)overmedicated neurotics and undermedicated psychotics;
- i)taxi drivers with hemorrhoids (makes them itchy, edgy, jerky, and ultimately unsafe);
- j)the illiterate, dyslexic, and/or non-English-speaking folks who suddenly make a dash across three lanes to a highway exit because it's always a surprise -- they had no clue what "next right" meant when they saw it;
- k)teenagers deafened by constant exposure to high-decibel art, and senior citizens whose Miracle Ear device had been accidentally damaged by same when they visited their grandchildren last Christmas;
- l)everybody who's in a hurry; also everybody who has all the time in the world, because the former tend to tailgate the latter with malicious intent, creating dangerous conditions;

m)in fact, nearly everybody except maybe for those who ride a bicycle -- provided the latter aren't stupid, deaf, overmedicated, suicidal, etc., in which case they must be banned from the roads too.

Anyone for a stroll in the idyllic countryside I've just created by assertive and wise legislature?

\*Legally blind\*, in all legislations that I am familiar with, is defined in terms of \*BEST CORRECTED VISUAL ACUITY\*, not uncorrected VA. This makes sense. I believe most, if not all, people on this list have BCVA better than the threshold to qualify as legally blind.

There is no such thing as "PRIO glasses". PRIO is simply a testing device for near vision which tries to simulate letters on a computer screen. Glasses prescribed using this device have been termed by the company and flashy magazine scribblers as "PRIO glasses". Again, these are absolutely standard glasses.

I received some materials from the company recently (after having asked for it 7 months ago) and this is all there. I also called the company and

they confirmed this. Glasses prescribed with the PRIO testing device are said to be computer-optimized and sometimes carry a little bit more plus (relatively) than normal distance glasses would do.

As Larry mentioned, this device is nothing new (I wonder how it was patented) and such near vision testing devices have been around for quite some time.

My eyes are 20/50 and 20/100.

With my 20/100 eye I can read license plates at about 30 feet. That you can't read them much at all makes me think you are legally blind without your glasses, visual acuity without glasses worse than 20/200. What that means is that objects have to be at least five times closer to you for you to see them, than to a person with 20/40 vision.

What was your uncorrected visual acuity last time you had it checked by an optometrist?

Since I don't work for the highway patrol, I don't HAVE to be able to read tag numbers. I can identify car makes and models, recognize roadsigns and streets. I can make out the color of traffic lights at a half mile, though they tend to be larger glows than I see with lenses (that may actually be good).

My last thorough optometric exam was in February 1996. Full correction:

R -5.50 -75 axis 175

L -5.75 -75 axis 5

I felt that was an over-correction. On my eyechart at home at that time, I could read the 20/20 line with -4.00 correction (no correction for astigmatism). I arranged the exam to get a script for -3.50 glasses, no cylinders, to wear as transition lenses. I now wear -3.50 contacts, with +2.00 glasses for any close work, like reading or the computer (I do a lot of both). By my personal benchmarks, I see as well now with the -3.50's as I did with the -4.00's back in December. I take an occasional day with no correction to work in the yard, do short errands in the car, swim with the kids, jump on the trampoline, juggle, etc.

For those uncomfortable driving without lenses (this is a very personal,

individual matter) I suggest riding as a passenger with no correction. A long roadtrip/vacation can do wonders for distance vision, especially with practice zooming mixed in.

For me, it was a mistake to allow someone else to judge how well I can see. I don't plan to make that mistake again.

Oh,I almost forgot to ask: What colors are your car tags? Ours are white background, with pale green lettering and peach accents. Or vice versa. Not too bad when they are "fresh," but they fade fast in the south Florida sun :D

Right on, Mary! It would be a VERY interesting experiment to see the difference in opinion if Nick could see through my eyes for just one minute. Generalizations have their place, and yes a high myope should not be driving without any corrections. However, all of us perceive the world differently under varying conditions and by trying to pigeon hole each of us to an unverifiable standard, the result would probably be something similar to what Elena alluded to in her post.

Be seein' you...

Yes, cars are very big. I don't dispute that a person would have to be practically blind to be unable to see an entire car in daylight. But cars are not the only things on the road.

I think that the real cause of the difference of opinion between myself and some others, is that I think of a car as a potential killing machine, not simply as a convenient method of getting from one place to another.

KGH

Hello,

The issue isn't really whether one can see an object such as a big car, but rather the reaction time of the driver. If things are not clear, time may be wasted trying to focus and make out shapes, rather than reacting to danger. Think about it, in one second, driving at 60 mph, you are moving a 3000 pound object 100 feet. You need all the time you can spare to react to sudden unexpected dangers. You may be squinting to read a street sign when a child suddenly runs in front of your car.

There must be better places to work on improving your eye sight than on public roads where you are putting your and others' lives at risk.

By the way, on another subject, those who are using computers a lot may want to look into computer glasses which reduce the glare from the screen. This may have already been mentioned here before. DOC carries these and they say these reduce eye strain.

Sincerely  
P. S.

Exactly! If someone is driving with 20/200 vision or 20/500 vision, objects will have to five times closer to be seen than for someone who has visual acuity at the legal 20/40 limit or better. Which gives you one-fifth the time to react, and you may not have that time.

Or, you might crash into a bicycle that's moving unpredictably while squinting at a car ahead ...  
or believe a car ahead is parked while it's actually backing up towards you -- or not see a car that's gray until it's too late, because with your blurry vision, it blends into the road.

People are not the best judges of their own driving safety, which is why there are laws about visual acuity required for driving.

It is similar to driving intoxicated. A lot of drunk drivers probably got in their cars believing they were "safe enough" to drive. And most of the time, drunk drivers do get where they're going without crashing. But their coordination and reactions are badly impaired, and over time, they kill a lot of people. This is why there are laws against drunk driving.

Similarly, if a person is driving with severely

impaired visual acuity, they are much less safe than driving with their glasses. That is why there is a law against doing this. Not having gotten into an accident so far, does not mean it is safe, only that you've been lucky and nothing unexpected has happened.

With a nearsighted correction of 3.5 D being a definite undercorrection for you, it is hard to imagine that your uncorrected distance acuity is any better than 20/200, which is *\*really\** blurry.

The drivers without glasses do *\*have\** glasses or contacts. Driving is a situation where you're operating a machine, weighing more than a ton, which moves really fast, around other heavy machines which are also moving really fast and may be driven by drivers who are unskilled and are doing unpredictable things, and small vulnerable objects like people on bicycles and children. You *\*need\** much better vision for that than for just walking along or riding a bicycle, because you can do a lot more damage. Working on vision improvement by driving without wearing glasses, for a person who's highly nearsighted, is terribly unsafe. Why not wear the 3.5 D undercorrection contact lenses at least? Even those might not get your vision clear enough so it's legal to drive, but it would be a lot safer.

# update

---

- *Subject:* update
  - *From:* [furmark@pipeline.com](mailto:furmark@pipeline.com)
  - *Date:* Tue, 16 Jul 1996 17:03:41 GMT
- 

26th of december 1995 my starting prescription was

-5.50 R  
-5.75 .25 180 L

one month later jan.1996 I had my first eye exam with rather exciting results.

-4.75R  
-4.75L still a slight astigmatism

I was fitted with some T glasses at -3.50 each eye no correction for the astigmatism.

I went back for another exam on April 23rd and the results were

-4.25 each eye no astigmatism

I went back again last week and here are the latest results.

-4.25 left with the best result from the test for astigmatism, very clear difference between examples.

-3.50 right with slight astigmatism. never had an astigmatism on the right eye in my life.??

I asked to be fitted for -2.75 no correction for both eyes.

I had a headache during test and have been rather lazy about keeping up my exercises. I felt uncertain about the results.

Just thought I would pass on my update best of luck to all,  
alexandra

Has anyone discussed this theory with their optometrist? Does it have any current support?

It sounds plausible, but given that most people are said to take in too much salt already (even without the use of 'table salt' that Josephson recommends) and that it leads to hypertension, I think it could be a dangerous thing to experiment with without further knowledge. (I take the point about fats, vitamins and proteins being important too, but he still recommends table salt).

NB - Wouldn't it be great if the answer turned out to be, "some extra salt is good"! I could stop trying to buy salt-reduced products.

Caroline

From: Alex Eulenberg

To: I SEE

Subject: Effect of Salt on Myopia

Date: Saturday, 13 July 1996 11:20AM

The topic of salt and its apparent anti-myopic effects has come up again. As far as I know, the only published material dealing with the effect of salt on myopia is that by Emanuel M. Josephson, MD, a renegade physician who published in the thirties and forties. He found that an increase of intake of table salt can lessen myopia. His theory was that myopia was caused by a salt-water imbalance in the body. Note, however, that his cure was not "eat salt and see" but rather, he advocated eating well, in general. He put particular emphasis on vitamins, fat, and salt. As Mary, Tara, and Elena have been saying, conventional wisdom regarding "good" versus "bad" foods is not always the absolute truth.

For more on Josephson's "salt-water imbalance" theory of myopia, see

[http://ezinfo.ucs.indiana.edu/~aeulenbe/i\\_see/josephson.html](http://ezinfo.ucs.indiana.edu/~aeulenbe/i_see/josephson.html)

- 

For those of you who can't avoid working with computers, why don't you learn to touch type?

I've always been able to do it, but in spite of good habits like making myself look up frequently and all the things I've learnt from what you all write on the list, only today has it occurred to me to shut my eyes as I type and to resist checking what the result is until the end of the command/sentence, instead of looking at the screen watching the words appear for the whole time I'm typing.

I'm amazed at the more relaxed feeling I'm getting after just a morning of trying this.

I have also started switching off my screen (not CPU) when I won't be looking at it for 10 mins or more - just for the radiation side of things, and palming with one eye whilst I'm on the phone.

~~~~~

By the way, I've started going to see a behavioral optometrist (recommended by Robert Kaplan - thank you). My eyes are -0.5 and -1.0 so I don't wear my lenses at all these days (except glasses for driving in strange towns or in very bad conditions - am I under the 20/40 limit you have in America?

What about if one eye is under and one eye is over, are you still legal?).

For the first fortnight I was told just to patch each eye for 10 mins a day, and to let myself recognise (rather than ignore) the feelings that were generated (extreme frustration at mis-judging where the bread is in relation to the knife with butter on it mostly!)

I didn't expect any results in just two weeks of only this treatment, but although my acuity was more or less the same (minutely improved in one eye),

my 'flexibility' (what is this?), peripheral vision and speed of re-focusing were improved. I've been sent away for 4 weeks to try patching for up to 30 mins, sunning, palming and that exercise with the knotted string because apparently my eyes are a fraction too relaxed in relation to each other.

(I've never had this last problem before. Could it have arisen from plus lenses? I tried fairly strong (+3 I think) plus lenses for reading a couple of months ago and felt instinctively that I shouldn't be doing it with both eyes at the same time. I wonder if it did any harm).

Caroline

Hi,

Just inquiring if Laser Eye Surgery is possible for people with Astigmatism. I'd really appreciate if someone could point me to any internet resources on that issue.

Also on another note, Can anyone recommend any Laser Eye Surgery contacts in Toronto, Canada?

Regards,

Thomas

Could it be that by patching one or the other eye during your initial

work that you lost some of your "teaming ability"? (temporarily, of course). If you had never patched before, that might explain why you never experienced it before. I have been using +2's without any loss of teaming, (and that with my undercorrection should be about the same as +2.75). I didn't use patching, though - I was uncomfortable with it (it is HOT here, and too sweaty).

With such low numbers, I bet you'll be where you want to go with this soon. I am a little envious :D Best wishes!

I think people get used to what vision they have and don't necessarily think of it as needing improvement to be good enough to be safe to drive. But if a person's vision is below the legal limit without glasses, they shouldn't be driving, even if they're used to that vision and it feels safe. We can't avoid entire counties to stay away from severely impaired drivers.

Imagine if someone got on a plane and they heard:

"Hi! I'm Captain Bob, your captain for this flight from Los Angeles to New York. I don't like my glasses, so I won't be using them on our flight today ... But don't worry! I've been flying this way for months and nothing has happened! And my vision is 20/300 !!! So much for the FAA and its silly rules about vision! Besides, the controllers take care of the tough stuff like seeing where the planes are, and they'll tell me if I'm about to hit one ... Never mind if you feel a little bump on takeoff. I can't see the ground crew walking around on the runway, but they're small and we're big, so what if we run over a couple?"

I bet people would get off the plane!

But with driving, we can't "get off the plane". Drivers have to share the road with a bunch of other cars, and in order to keep it fairly safe, they

rely on a couple of things:

1) That people won't drive while very impaired, like drunk or with seriously impaired vision --

2) Now and then, cops will ticket people or they'll have court trouble if they drive while very impaired, or they'll get in accidents and learn not to do it.

But, since there aren't that many cops around, we mostly rely on # 1, that people will be careful that they're safe enough to drive. Actually, it would make sense for a person with 20/40 uncorrected vision to use their glasses while driving ... because the more visual acuity a person has, the better off they'll be while driving.

Did the optometrist tell you what your uncorrected visual acuity was?
Yes, they give the driving test here with both eyes, so if one eye is
20/40 or better, you'd probably pass.

>versa. Not too bad when they are "fresh," but they fade fast in the
>south Florida sun :D

Here in the Northeast (New York), they are red lettering on a white background with the Statue of Liberty on the left side. VERY visible during the day from a far distance. At night, the plates have a reflective surface that really shines when hit by headlights or any other source. Most of the plates have raised lettering to enhance the effect, but the special vanity plates do not. Strange, they seem to have been made in a cheap knockoff shop instead of having the modicum \ of quality that the others have. Pay extra; get less!

Pretty amazing in my opinion! I wish I could get that kind of results that quickly. Although for me it has been 12 days as I write this since I began this quest, I have noticed a substantial improvement in my eyes (both!) ability to focus and re-focus after using glasses, both minus and plus.

I should probably set up an appointment with my eye doctor to see if any improvement can be measured. In visual acuity, I can detect a difference, but don't know if the optical instruments can see what I can.

Good luck and don't slip on the exercises! These numbers give me a good reason to continue!

It is amazing to me that this whole deal about salt being the culprit in so many disease mechanisms still exists to this day. If you look, even superficially, at the human body, you will see that salt not only plays an important role, but without it we would be dead! Salt, among other chemicals, provides the medium to fire off nerve transmissions, helps in muscle contractions, supports brain processes, etc. Yes, we could take to much of it, and too much of anything is NOT a good thing. But look at what has happened in the cholesterol arena. If has been

proven that lowering your levels too much can cause a lot more problems than if you had left it alone.

Many years ago I decided to stop adding extra salt to food. Instead, I acclimated myself to the natural saltiness (if any) in food and found that I like it just the way it is. However, after reading Josephson's article, I just might try a little salt over time and see how it manifests itself in my vision.

Yes, and they do it in Canada for large amounts of astigmatism. Richard Adams who reads sci.med.vision had it done for about 5 D of astigmatism. I recommend you post on sci.med.vision to ask for experiences with the surgery.

jaw relaxation technique

- *Subject:* jaw relaxation technique
 - *From:* Scott Lorbeer <ussl@msu.oscs.montana.edu>
 - *Date:* Wed, 17 Jul 1996 09:47:07 MDT
-

Greetings all,

I came across an exercise or technique in a health magazine that relaxes the jaw. Perhaps you do not know that the masseter, the small muscle that pulls the jaw shut is the strongest muscle for its size in the body (I think I am correct here, but wouldn't bet much money (-:) And you all from time to time probably notice stress in it.

In the faq, (which BTW is great, thanks for the work in putting it together), relaxing the jaw and other head and neck muscles is highly recommended.

Try this: Lightly press or touch your tounge to the roof of your mouth directly behind your front teeth.

I find a relaxing of my jaw, in about 2-3 seconds -- which then makes me aware of how much my "squinting muscles" around my eyes have been working.

I don't think the tension is "flowing" into my eyes, but it sometimes seems like it because the jaw tension masks the squint tension.

I do wonder where the tension goes, if it goes anywhere. I know I am much more aware of the tension in my eyes. What do some of you do who also feel that squinting feeling?

Hope this helps,

Scott

P.S. Do beat a dying horse...perhaps already dead, bloated and stinky...

I always drive with my glasses, but sometimes think when I am tired and it is late at night, and I am on a two lane highway, that my vision in this situation would call for a completely different prescription than the one the OD gave me while sitting in her cozy office. At least in the moment when I feel the howling of panic trying to take over as the bright lights approach, I have a good sense that my car is in my lane. I just hope there are no deer around right before and right after the car passes in the other direction.

*** happy trails

More ideas on the salt connection.

Most table salt contains iodine. For some of us with a fish-poor diet, this may be the only way we are taking in the iodine we need. Thyroid function is the primary purpose of a good iodine intake. The thyroid maintains our metabolism. Too little thyroid function results in hypothyroidism and decreased metabolism, weight gain, and goiter.

Hyperthyroidism (increased function above normal of the thyroid gland) may result in Grave's Disease and exophthalmia, bulging eyes and eye dysfunction.

A lack of iodine, however, would lead to a hypo-function and so far the only quote I have come up with relating this to vision is below>

Iodine deficiency can lead to "goiter and cretinism and vitamin A deficiency, a leading cause of childhood blindness." Infopedia

I will continue to check into how iodine deficiency may lead to a Vitamin A deficiency and let you all know (unless some kind soul beats me to it...my thanks in advance!)

Perhaps this might help us if we are worried about too much salt (NaCl, Sodium Chloride) intake.

Foods rich in iodine include kelp/seaweed (health food stores stock kelp tablets), rice (small amounts of iodine), and pears.

" It is also derived from sea organisms such as brown seaweeds, particularly Laminaria, that concentrate iodine in their tissues." (Infopedia)

"Uses. Iodine is medically of great importance because it is an essential trace element, present in a hormone of the thyroid gland that is involved in growth-controlling and other metabolic functions. Without iodine, stunted growth and conditions such as goiter (q.v.) can result. Thus in areas where iodine is not sufficiently abundant naturally, iodine-containing salt serves

to make up the deficit. " (Infopedia)

Many bright flashes to everyone this week...Of the visual kind, of course!
:-)

Julie Skokna

In a message dated 96-07-13 15:47:05 EDT, aeulenbe@indiana.edu (Alex Eulenberg) wrote:

<< The topic of salt and its apparent anti-myopic effects has come up again. As far as I know, the only published material dealing with the effect of salt on myopia is that by Emanuel M. Josephson, MD, a renegade physician who published in the thirties and forties. He found that an increase of intake of table salt can lessen myopia. His theory was that myopia was caused by a salt-water imbalance in the body. Note, however, that his cure was not "eat salt and see" but rather, he advocated eating well, in general. He put particular emphasis on vitamins, fat, and salt. As Mary, Tara, and Elena have have been saying, conventional wisdom regarding "good" versus "bad" foods is not always the absolute truth.

For more on Josephson's "salt-water imbalance" theory of myopia, see

http://ezinfo.ucs.indiana.edu/~aeulenbe/i_see/josephson.html

"Table salt" is not the "salt" our bodies need! Since the 1930's, SOMEBODY decided that all "table salt" should be oven-dried at temperatures above 1200 F. The result is the heat destroys the mineral contents of "table salt", as well as the Iodine that all salts contain in adequate amounts to supply the human body.

That explains why the "table salt" bought from a store has iodine added, because it was burned up in the oven-drying process. Oven-drying also changes the chemical makeup of salt (sodium) to sodium chloride (as I recall), and the calcium content to calcium chloride (again, as I recall) which are NOT water-soluable.

Our bodies are 87%+ - water. What do you think your body can do with salt and the mineral contents that have been altered or destroyed? NOTHING! It gets pushed around your body, and dumped wherever your body thinks it can best be utilized. "Calcium deposits" and "Bone spurs" are 2 fine examples of many, many more.

Sun-dried Sea salt (with NO oven-drying) is the answer. You can obtain it from your local Health food store. Place a pinch of the sea salt in a shot glass of water, and another pinch of "table salt" in another shot glass of water. Swish both glasses a little. Within minutes, the sea salt will be completely dissolved, but you will be "pushing up daisies" and the "table salt" will not have dissolved, and NEVER WILL!

Moral of the story? TABLE SALT IS POISON!!!! Sea salt is NECESSARY for your body! It contains ALL of the 40-some essential minerals plus Iodine and Calcium IN ADEQUATE amounts to keep your body healthy. You may consume as much sea salt as you desire, and it will not harm you. In fact, it reverses the hypertention, deposits, and all of the harm that "table salt" has caused rapidly.

This is one of many interesting (scams?) changes SOMEONE(s?) has made since the 1930's to our essential food supply. When did all of the "incurable" diseases begin to become rampant in the "modern world"????...

"TABLE SALT" IS POISON!!!!

I smell a LARGE RAT in the woodshed!!!! (Somebody get the gun....)

Interesting!

I was diagnosed last year with trigeminal neuralgia -- the first (and worst) episode lasted for over three months, and one of the things that helped the most was a suggestion from my father who seems to have passed his "tense everything" gene on to me! He said I should try sticking the tip of my tongue between my front teeth and just *stay* like that for a bit.....obviously, I don't do this in public places.....it helped quite a bit, and my subsequent bouts with pain have been much milder. Those muscles are connected to positively EVERYTHING --

(duhhhhh!) :)

-Tara

Salt, NaCl, is wait for it... Sodium Chloride... Na, sodium, cl,
chloride... you obviously can't change it FROM salt (NaCl) into sodium
chloride (NaCl), it's already there. as to having calcium in salt, if
so, then it's simply an impurity.. it's like finding rocks in you can
of pepsi.

as to the iodine, that's an impurity in salt too... it's just a
beneficial one that's added because so many people were not getting
enough iodine in their diets.

So...would a person drinking pasteurized milk be likely to get calcium
deposits before a raw-milk drinker? (Again, a **serious** question.)

Is that a sure test or is it advisable to call the company that produces the
sea salt? (Concerning whether it's sun-dried)

Hmmm. If any of this is true, I've been a very good girl for 7 or 8 years
now, having been attracted to sea salt due to the alleged trace mineral content.

I haven't written for a while so here's some of my opinions.

To be honest I think that driving without glasses if you really need them is not worth the risks. The roads are dangerous enough as it is. At around -9 you will be relieved to know that I will be keeping my glasses on while driving for a fair while.

Regarding salt, I tend not to add any to my food, but have the odd meal with processed food. How can you tell if you're getting enough? I wonder if I need more as I had a bad cramp in my leg as I was getting up yesterday. I expect that with the amount I am losing in sweat that my salt level must be lower than usual.

On another topic, I've recently taken up Aikido. I have been doing most of the lessons with my glasses on so that I can see the demonstrations, but last week the instructor said I should take them off because we were doing more advanced work now. He reckons I did a lot better without them and that I may subconsciously have been holding back because I was worried about breaking them. I'm not sure about this, but I did the last lesson without glasses and managed pretty well.

Generally, I'm not really sure how my eyes are doing. My last visit to the optician showed no real improvement. I walk around in the sunlight without glasses, but under these conditions the contraction of my pupils is probably giving a misleading impression of improvement.

Keep smiling :)

Some very well reasoned but patriarchal essays have been written about the driving without glasses issue. Next is bound to come a new organization, mobilizing to protect the 'innocent' citizenry: Dads Against Myopic Drivers! It's an unfortunate feature of our times that people still think that laws and other black and white programs will bring about a safe and happy planet. These statements that " x visual acuity is necessary to be a responsible driver" is an example of this type of thinking and is not really useful.

The analogy to a drunk driver is specious. Besides the obvious difference of drug disorientation, for this analogy to be reasonable, then it would also be reasonable to ban coffee drinkers, people who are getting divorced or just lost their job, and spandex wearing joggers! My point being that taking attention away from the driving is the real problem, and people screw up all the time with or without excellent vision.

None of those who reported their good results driving without glasses spoke about the benefits of blurry vision or that 'everyone should do it'. It is disrespectful not to assume that they may have good enough judgement to know when they are being safe, and act accordingly. If one truly wanted to help, one might consider exploring what factors make up a truly safe driver. Maybe also ask what things this myopic driver may have learned to make themselves a safe driver instead of assuming they are simply trying their luck at surviving while driving blind. These statements are usually just projections and prevent everyone from learning anything.

These concise proscriptions also indicates an ignorance of the full process of vision, especially as it pertains to driving. Besides acuity, there is the sense of motion, peripheral awareness, and calm collecting and parsing of the visual field as it pertains to making safe decisions and reactions. In the full throes of myopia, it's hard to imagine what really seeing is

like, but the mental component is huge and putting glasses on when in that good state is as upsetting as taking your glasses off after being tuned into the myopia mode.

There are irresponsible people out there and stupid people, dealing with that problem is not the purview of this list. Noone recommends driving without glasses as a necessary exercise, but in fact, i believe it is a necessary step everyone will be taking on their way to complete independence. I am at a point where i sometimes have to leave my glasses off to function best. To leave them on because of someones arbitrary ruling would NOT be the best for everyone concerned. I know this because I'm a Dad and i just know!

Cordially,

Bill Stender

Hi,

I just happened to notice this very large ad in this week's TV Guide, Thomas that may answer your question.

"See Clearly, The Beacon Way, with Laser-PRK"

They will send you a free video if you call:

1-800-775-8632

They have a Laser Center in Toronto's BCE Place

And of course, a web site

www.beaconeye.com

Let us know what you find out.

- Linda

Here, I must beg to differ. Salt, chemically is NaCl - or Sodium Chloride. Salt is NOT Sodium. As a matter of fact - Sodium is a Metal (and if I recall correctly - highly flammable too).

Actually, according to Websters dictionary Salt is:.."1. Sodium Chloridde... NaCl...A salt is usually what you get when you combine a metal and an acid.....in chrystaline form..... (Hydrogen gets replaced wholly or partly by metal...bla bla bla...) " .

According to Websters..Sodium "(is)..a soft, silver white alkaline metallic chemical element having a waxlike consistency...."

Well, hope that helps clear stuff up.

Has anyone been a patient of Ben Lane in NJ? My daughter saw him about three weeks ago, and finally we got a new prescription for the nearsighted glasses(bifocal for school -5/-5 and reading glasses -3.75/-3.75) , the opticians that saw this prescription all laughed at it, it seems very amusing to them someone put out such a "old fashion" prescription , using plastic glasses for kids. Got concerned, and wonder what to do next.

Muscle tensions (was Re: jaw relaxation techniques)

- *Subject:* Muscle tensions (was Re: jaw relaxation techniques)
 - *From:* Elena <solusrex@soho.ios.com>
 - *Date:* Fri, 19 Jul 1996 12:34:49 -0400
-

I have read a lot of stuff in nontraditional psychology in the past few months and have accumulated a huge amount of evidence of the way repression of emotional release translates into unconscious muscle tensions that impair various functions of our various organs. In many kinds of unorthodox, "body-inclusive" therapies (Reichian, Rolfing, Janov's Primal, the Orientally derived ones like Reiki, etc.), the aim is to release muscle tensions TOGETHER with emotions that are "locked in." The originator of this approach who made one of the first attempts to formulate it in "Western" (rational) rather than "Eastern" (mystical) terms was Wilhelm Reich, a brilliant though much maligned and virtually drowned in slander heretic scientist whose early work was rooted in psychoanalysis but then took a separate and wildly dissenting route, causing him to split hairs first with his mentor, Freud, and then with everybody and his brother, including the FDA (the latter had found his books important enough not only to ban them but to have been burning them, physically, for three years back in the fifties and again in the sixties). Reich thought that tensions stored in what he called the "ocular armor segment" must be released by opening one's eyes very wide, as in fright, and making other HIGHLY EMOTIONAL PHYSICAL MOVEMENTS involving the eyebrows and the forehead. A Reichian "armor segment" (of which there are supposedly seven, the ocular one being the first one) is radial, so anyone who has ever experienced (like myself) uneasiness or pain behind the ears while wearing glasses knows where this "segment" spreads at the back of your head. Well of course I tried to do it -- opening my eyes really wide and making grimaces of terror or wild surprise, etc. . I was also prepared to FEEL anything that I might feel with this facial expression without controlling or stopping any emotions from emerging. (You have to be alone to do this, naturally, or someone will think you've gone nuts. Another interesting instance of noticeable differences between outward manifestations and the inner MEANING of our

activities. Btw, in the past few months, I've become rather proficient at deciphering WHY people do what they do, what it is that drives their desires... There's some real risky reading out there, there's not only Reich but also Arthur Janov, try it and watch what happens to the world of universally accepted, seemingly unquestionable values...) At some point, I felt a tremendous amount of pain and pressure and strong pulling sensations behind my ears. I won't describe all the effects -- try it, in front of the mirror, and see if anything happens -- but I remember a few weeks ago a member of the list wrote about accidentally discovering that opening his eyes very wide improved his vision. And someone else wrote that he was unable to open them wide because of some uncomfot or pain. Both were right on. This is something to practice, and the initial uncomfot will go away, restoring mobility to many muscles. I've checked my childhood photographs and discovered that I kept my eyes open a lot wider in pre-myopic years. (Have you ever noticed that infants' and very small children's eyes are practically round?) After doing this exercise for a while, not only do I find it very beneficial for the eyesight, I seem to actually LOOK more like my childhood photograps -- there's a peculiar quality to it, something like recognizing your own "real" face after you haven't seen it for a while...

The jaw muscles store tensions of the repressed impulses of "crying, screaming, and vicious biting," according to Reich. (Why do you think we "clench our teeth" when we're very angry?) However, except for viciously biting my toothbrush, I couldn't see much opportunity to work on those under everyday conditions, so I checked the literature on yoga. Sure enough, there are many exercises that are aimed at restoring flexibility to the jaw, tongue, and deep throat muscles, and, sure enough, some of them are designated as "exercises for the eyes!" Makes sense in the light of Reich's explanation that deep throat muscles are involved in choking back tears -- literally "swallowing" them -- and I've long suspected a strong connection between my myopia and the fact that I never cried between the ages of 4 and 21. (Many parents, and later teachers, successfully convey to some impressionable children an unconscious idea that they aren't important enough to attract as much attention as crying does.) Another confirmation I found in a study of the chemistry of tears. William Frey, biochemist at St. Paul University of Minnesota, has discovered high concentrations of stress hormones in tears. (This is not the case with non-emotional tears caused by eye irritants.) Here's a quote from Arthur Janov's "Prisoners of Pain" (he talks about biological aspects of neurosis, but of course it's not only neurosis that can result from an altered hormonal balance but what-not -- any organ or system, especially at the stage of development, will be influenced by the adulterated biochemical milieu it finds itself in when emotional release is repressed. In fact, my another suspicion has always been, myopia is a biological alternative to neurosis -- take your pick of distortions says the stress to our bodies, I have to manifest myself somehow, I need an outlet! -- and some of us will unconsciously choose what's socially more acceptable and become myopic rather than neurotic,

while others will become allergic or obese, etc.):

"Clearly, if there is indeed a release of stress hormones with tears, then the blocking of that release must result in the buildup of stress hormones. We believe that crying is an important biologic function and that the shedding of tears is central, not incidental, to the resolution of neurosis. There is no such thing as 'talking cure.' The fact of weeping itself helps relieve suffering. Tears not only remove toxic substances of the eye, they also have a precise role in the removal of toxic biochemical substances from the entire system."

With yoga exercises that work on the muscles of the jaw and throat, I had the same experience of "release" of muscle tensions (starting with painful, pulling sensations) as earlier with the "ocular segment." An unexpected additional benefit: my singing voice which used to be rather lousy improved considerably (this must also have a lot to do with breathing exercises). Remember the opera singer who wrote about how he came across the idea of working on his eye muscles in a fashion similar to his voice technique exercises? Looks like I've traveled the road the other way around. Book some Metropolitan Opera seats soon -- it's gonna be packed!.. On second thought, don't. I just don't quite feel up to it. -;)

Here's another interesting quote, very illustrative of my own unexpected reactions a while back -- from "Out of Sight Into Vision," by Neville Cohen, OD, and Joseph Shapiro, OD:

"According to optometrist Dr. Lawrence Macdonald, 'optometric visual training involves rematching the visual and kinesthetic coordination. As the kinesthetic system begins to re-adjust, old memories and experiences may surface to the conscious level. Some of these may be loaded with emotional content.' In his excellent article, 'Implications of Critical Empathy, Primal Scream and Identity Crisis in Optometric Visual Therapy,' Dr. Macdonald goes on to point out that at a certain stage of vision therapy, a stage he calls 'critical' or 'breakthrough time,' optometrists have observed a curious response which seems to have its counterpart in psychotherapy. "At this time, the patient first comes to terms with his visual space world. A simultaneous release of pent-up, emotional energy that accompanied previous associations and half-forgotten memories occurs, resulting in sobbing, crying, and general disorientation.

"Some of the fears and anxieties experienced during vision therapy are difficult to describe. Patients gain a certain insight into things and reach a level of understanding not otherwise possible, nor normally within their grasp. They become more confident and can operate more efficiently in their environment, however artificial it may be."

Btw, I've contacted Dr. Janov's International Primal Center with the question whether any of their patients who happen to have refraction errors (and who come with emotional problems, 'not' with vision-related ones), have experienced any incidental changes in visual acuity. As I expected, the

reply was, verbatim, "some of our patients report spontaneous vision improvement in the course of Primal therapy but this result is not to be expected in every case."

Bill Stender <BillS@vav-nun.com> writes:

> Some very well reasoned but patriarchal essays have been written about the

You have no reason for that "patriarchal" label. Maybe it's "patriarchal" thinking to go around with impaired vision in a large machine that can do a lot of damage to small objects like bicycles and children, and not think about it.

> driving without glasses issue. Next is bound to come a new organization,
> mobilizing to protect the 'innocent' citizenry: Dads Against Myopic
> Drivers! It's an unfortunate feature of our times that people still think
> that laws and other black and white programs will bring about a safe and
> happy planet.

Having laws helps make driving safer. They are necessary because people otherwise will make up their own rules, such as "it is perfectly fine to drive with 20/300 vision". People who can't see well enough even to read license plates are not seeing well enough to drive. Similarly if there is no enforcement against drunk driving, you would get a lot more drunk drivers deciding they're OK to drive. If people driving without glasses who have very poor uncorrected vision becomes a big problem we probably will have a "Dads Against Myopic Drivers", and it will be needed.

Luckily, most people who need glasses to get their visual acuity to driving level do wear them, because it's easy, it makes sense and it makes driving easier. It only makes sense to wear glasses while driving if one needs them to get good visual acuity. If a person isn't a gang member with a semi-automatic, driving is the time when they have the most potential for causing physical harm to another. We have laws to regulate this activity exactly because drivers can cause a lot of damage. That is why laws require a certain amount of visual acuity. There are no laws about riding a bicycle with poor vision

because if someone gets hurt it's probably the bicycle rider. It only makes sense to get one's vision as good as possible when driving -- and bicycling, for your own sake -- even if it weren't legally required.

> None of those who reported their good results driving without glasses spoke
> about the benefits of blurry vision or that 'everyone should do it'. It is
> disrespectful not to assume that they may have good enough judgement to

> driver. Maybe also ask what things this myopic driver may have learned to
> make themselves a safe driver instead of assuming they are simply trying
> their luck at surviving while driving blind. These statements are usually
> just projections and prevent everyone from learning anything.

We have laws exactly because people can't be a law unto themselves when they are doing things that can injure or kill another person. The labels that you're throwing around -- "disrespectful", "patriarchal", etc. are ad-hominem and really irrelevant.

Part of the problem with highly myopic people driving without glasses is that if they cause serious injury it is likely enough they will injure something smaller than they are. People may feel safe riding around in something large. However the smaller less easy to see objects near the road -- bicycles, children, motorcycles, are especially at danger from them. You ask bicycle riders how they feel about drivers on the road with 20/300 vision.

> These concise proscriptions also indicates an ignorance of the full process
> of vision, especially as it pertains to driving. Besides acuity, there is
> the sense of motion, peripheral awareness, and calm collecting and parsing
> of the visual field as it pertains to making safe decisions and reactions.

Of course there are many components to good vision. Someone might pass the DMV visual acuity test but have very limited peripheral vision and not be safe to drive. A lot of visual skills, *including* visual acuity, are necessary for driving. This doesn't mean one can ignore the visual acuity if one has the other visual skills.

The argument *for* driving without glasses with poor vision seems to be based on ideas of "independence" and not wanting to depend on an external aid. These ideas are fine. But they also need to mesh with practical realities and the reality of *other* people's safety. Driving is a technical skill that requires among other things certain visual skills. Doing it without at least the minimum legally required visual acuity endangers other people. You ask a bicyclist who's been crippled by a legally blind driver how *they* feel about *their* "independence" and so on. They would probably be suing the legally blind driver for as much as they could!

> To leave them on because of someones arbitrary ruling
> would NOT be the best for everyone concerned. I know this because I'm a Dad
> and i just know!

> Cordially,

No, you are not cordial. You are slinging around a lot of labels and talking ad-hominem.

Polycarbonate has more chromatic aberration than many of the other materials. That means that you may notice color fringes on objects, especially in bright sunlight. However, it is nearly impossible to break so polycarbonate glasses are often used for sports like tennis. The chromatic aberration is measured by the Abbe value. So if you are concerned about chromatic aberration, ask for a material with Abbe value similar to crown glass. Also, polycarbonate may give less accurate refraction, but I'm not too sure about that.

Some of the other materials are better optically, but they are easier to break, and thus less safe.

Edythe;

CR-39 (plastic) is a little harder and less scratch-prone than polycarbonate. However, polycarbonate is the MOST impact RESISTANT (no lenses are impact PROOF). So for safety, polycarbonate is the best and is fast becoming required for many sports and industrial purposes as well as for kids who are rough and tumble. Just make sure if you get polycarbonate that they add scratch coating, which most do anyway.

Hope this helps.

 - *From:* "Art Blake" <art@blakesys.com>
 - *Date:* Sat, 20 Jul 1996 16:05:03 -0400
-

Hello, glad to be part of this group. I've been looking for a mailing list like this for some time.

Wanted to report that I am making good progress with vision therapy and the accomotrac. Started at -6.0 diopters in both eyes and I am down to -4.75 after 3 weeks.

I want to hear if any one else has any experience with the accomotrac. I feel like my vision has mostly improved due to relaxation techniques such as palming and breathing, but the accomotrac is real useful because of the biofeedback it gives me on how well my eyes are focusing .. oh, also I am visualizing my lens flattening properly and my ciliary muscles working properly. I think it helps to know how the muscles are supposed to function and then visualize exactly how they look when functioning properly, imagining that they are completely relaxed.

Re:Steev@darkside's comments about lighting giving a false impression of improvement. It seems that epidemiologically, a major factor in myopia is indoor, close-up work. Now if you're daily outside in bright light, the circular fibers of the iris should be contracting a lot more than if you were spending all day indoors. The muscle tone would increase. You would have more of a pin hole effect. It would be like the cardiovascular status of a person who spent all day walking delivering mail versus the same person sitting all day at a desk. Couldn't poor tone in these fibers contribute to decreased visual acuity? Anybody know of any published data on this?

I am not an expert, but it seems wiser to me to get the bifocal prescription than to expect your daughter to "adapt" to seeing with such strong lenses for both reading and distance. Some optometrists give young readers "plus" lenses to keep them from becoming nearsighted. Perhaps this prescription is meant to keep your daughter from becoming progressively nearsighted (as I did, wearing "minus" lenses to read AND see in the distance.

I now wear "weaker" correction to read and use the computer than I need for distance, and my vision over-all has improved. Some opticians have laughed at me, too, but not the last time I came in with a reduced prescription.

>Mei-Tien

Are you saying the prescription is for one pair of bifocal glasses -5.0
distance, -3.75 near? If your kid gets to tolerate it well, this would be
better than having to change glasses. As long as you agree that weaker
glasses help prevent myopia from worsening, you shouldn't be concerned by
the reaction of a bunch of narrow-minded optometrists. Many of us are in
this myopic plight exactly because of stupid ODs.

I am seriously considering trying bifocals (got myself a book on them) and I
repeat my yet unanswered question if someone has tried bifocals for VT and
what their experiences are.

Stefan

After 16 years of vision improvement efforts this is the essential conclusion i have come to also. This is the Great_Work we are involved in.

[...]

>emotional release is repressed. In fact, my another suspicion has always
>been, myopia is a biological alternative to neurosis -- take your pick of

>somehow, I need an outlet! -- and some of us will unconsciously choose
>what's socially more acceptable and become myopic rather than neurotic,
>while others will become allergic or obese, etc.):

My firm belief also. Ancient medicine held the prime theorem that all disease is congestion, as in, lack of free flow. The Eastern tradition still operates on the assumption that blockage of the ethereal energy flows of the body are the cause of pain or dysfunction. Chiropracty and other medicines also agree with this by one model or another.

>"Clearly, if there is indeed a release of stress hormones with tears, then
>the blocking of that release must result in the buildup of stress hormones.
>We believe that crying is an important biologic function and that the
>shedding of tears is central, not incidental, to the resolution of neurosis.
>There is no such thing as 'talking cure.' The fact of weeping itself helps

>the entire system."

A model I find most interesting holds that Emotion is the bridge between outer and inner worlds. The goal of every religion that i have studied is to recognize and establish the awareness of 'Oneness' between these two worlds. "As above, so below" et al. This removing of the dichotomy is facilitated and marked by emotional free-flowing. The so-called 'Astral Body' is also called the Emotional Body and the 'Astral World' is defined as the formative planes of reality, the physical being the most dense. I won't go off on this controversial model but just wanted to point out this major corollary to the *importance* of our Emotional selves. The implication is that our Emotions are not just our personal mental constructs, but very much 'chunks of reality' that can't just be dismissed--they are here whether you like it or not--deal with it!

Emotion is inconvenient to our society, control is still the word. Command of Nature, seen in the great dam projects, miracle drug medicine and petro-farming to name a few, has been the dominant pursuit for at least the last thousand years. This i believe corresponds very well to the belief that one can and should command and control one's Emotions and could explain our society's rampant stress and physical dysfunction.

I have put these books on my list Elena and literally could cry from reading your post because it touches on so much of what i have discovered and theorized and surmised from my reading and vision work all these years. I almost forgot about the list after my intro talking about the 'subconscious wall' was ignored, i'm so glad to find this now! More more!

Hello,  
I am looking for glasses -- what do people think about the very thin frames that are now being sold? They have wire with some plastic around them. How strong are they? Some of them are stainless steel and titanium -- how strong are those? Would they last for a couple of years?

Thanks!

  - *From:* "Linda Lee" <[llee@island.net](mailto:llee@island.net)>
  - *Date:* Mon, 22 Jul 1996 10:34:51
- 

Someone recently posted (was it Mark?) a letter about seeing better at the pool since taking up VT, and i have a comment.

Last summer, at a local swimming hole i accidentally tried out a young friends face mask and checked out the underwater view. I was blown away by the detail. For once i could see very clearly what was going on under the water. I swear i could see 20/20 as long as i stayed underwater. My usual correction is -5.

At the pool, i sometimes use those Speedo goggles, but since there really isn't much happening underwater and they leave great rings on my face, i usually don't bother. But in a natural setting like a river or the ocean, a full face mask allows me to see the fish, underwater caves, and what's really on the bottom. All new experiences for me.

I realize this has nothing to do with VT - it probably involves technical stuff like refractive angle focal length correction, but it was great so i pass it on, FWIW.

Tara

Many thanks for such an informative reply. I appreciate the time you've taken to share your findings. You got me thinking about calling someone from the water authorities in Sydney to see what they say (Australian water is fluoridated) and the company that markets my water filter to see if they can show me test results on the effectiveness of fluoride removal.

Wouldn't it be great if there were a test case where fluoride damage (bone cancer? other problems?) was judged to be related to fluoride and the local water company ordered to pay compensation. I bet that would stop the mass medication.

>

>Tara - I'm struggling with the fluoridated water question at the moment.

My

>dentist and most other people tell me that nothing has been proved. Has it?

To my satisfaction, yes! I strongly recommend that *\*anyone\** interested in finding out the truth about *\*anything\** invest him/herself heavily in the task and TACKLE it! I started digging around in this debate, not realizing how long it had been going on, and found people yelling on all sides. I always had believed that fluoride was necessary to dental health, and when I

picked up a flyer at the local health food store, I ignored it for a year, because \*everyone\* knows fluoride is good for you! :-0 I discovered later that while I had been given fluoride drops as a child, my brother had \*not\*, and guess which one of us made it through high school without a single cavity! \*He\* did (And ALL of my molars are filled at least once, and one of my baby molars fused to the bone). So, I started inquiring, and was amazed at what I discovered. The chemical realities are pathetically simple to uncover. You just go to the library. I also got the local WA State Dept. of Ecology to send me the book "Chemicals of Special Concern in Washington State", and found flouride "considered to be of high toxicity". (I have literally reams of material; these are only scraps.)

I called Bob Myrick, the man who heads up Tacoma's public water system, and he admitted to me that fluoride is "terrible stuff", but he says there's nothing he can do (sure). He says it's so poisonous that the employees insist on rotating schedules so they don't have to handle it for more than two weeks at a time.

I wish I could cram into one letter all the things I've found out.

I did notice that every time I asked the pro-fluoride people to tell me what \*form\* of fluoride was used in the studies they touted, and to tell me who funded the "research" I got hot air at best and USUALLY got insulted or even yelled at. I tried all kinds of approaches, but as soon as these people found out I was genuinely interested in finding out the truth (and not sympathetic to their cause or a sucker), they became absolutely hostile. I was accosted at an airport by a man who saw my 'stop fluoridation' button, and he spat "Fluoride's the best thing to hit the tit in the past forty years!" He was unbelievably obnoxious and vulgar. And not unusual. On the other hand, I've found that the unbelievers are kind, helpful, and if challenged will always suggest I go find out for myself. They never have asked me to trust them blindly, which is something I admire!

The initial study that launched this whole fluoride thing based its finding on a water supply that had LOTS of natural minerals in it, \*including\* fluoride. However, this was not raw waste fluoride left over from aluminum smelting or fertilizer manufacture (such as we use in the USA), but naturally bound fluoride compounds (read about that too!). There is nothing there or anywhere that suggests any benefit from the addition of unbound waste fluorides to soft water or any water. Too much of any nutrient can hurt you if you don't have other nutrients to help you metabolize it, and fluoride is quite the \*anti\*-nutrient!

The nearest toxic chemical dump to where I live is in Utah. It would be phenomenally expensive to truck all of that waste from here to there...though I believe we're getting our current batch from British Columbia; have no idea where they have to dump theirs. If you care to check it out, the very \*selling\* of the fluoride waste to cities conveniently changes its status from "toxic chemical" to something rather benign and

commercial-sounding. Makes it all better, in effect. We don't even get pharmaceutical grade poison! It is literally forced mass medication, and I can't switch water companies!

Indian reservations are required to be fluoridated by law. The level of tooth decay at all of them is incredible. I really hope you look into these things.

> He says that toothpaste is ok anyway, as long as you don't swallow it.

Probably won't hurt, especially if your water's not fluoridated. But children have gotten very sick from fluoride treatments and one died after he swallowed the concentrated solution. Even toothpaste can make children sick. I've heard there's enough fluoride in one tube to kill a small child, though I've never seen any reports that this has happened.

> I've also seen a report that suggests that my water filter, which claims to  
>remove fluoride, does no such thing. It's so difficult trying to take  
care  
>of your health!

Water filters (reverse-osmosis type) should remove most of the harmful compounds, as they mimic natural filtering processes. I haven't tested this myself YET, so am drinking well water and using distilled for mixing up juice.

>  
>Tara/Everyone else - I agree with the benefits of sea salt and the harm of

>table salt, but can you really take it to the degree stated below? If so,  
>that's great news, but I just thought that sea salt provided essential  
>nutrients, not that it reversed the harm done by table salt and that you  
>didn't have to try and not overdo it.

I seriously doubt that sea salt is a panacea, and I don't think that an occasional glass of fluoridated water'll kill you either! But fluoride is a proven cumulative toxin -- very easy to overdo -- and I feel significantly better with the addition of a little salt to my diet. I have no idea why. Time to hit the books again! This is really getting to be too much... :) Hope this hasn't exhausted you.

-Tara

BTW, my little boy has perfect teeth -- and not a speck of fluoride to be seen in the house! :)

I don't quite get the picture -- bifocals \*and\* reading glasses?  
The two different powers, for distance and for near work, are fairly  
standard I think with optometrists who think that wearing a full  
distance correction for near work could cause more myopia.

If your daughter is pretty young the bifocals might not work -- I've  
heard that little kids don't use the bottom part of bifocals because  
they look through the top part, focussing hard instead.

It doesn't hurt at all to get a second opinion -- I've noticed there  
is a wide variation in quality among optometrists and opticians.  
Some are much more careful than others. Paul Harris at  
[babo@ix.netcom.com](mailto:babo@ix.netcom.com) provides referrals to behavioral optometrists.  
They may cost more but perhaps do a more careful job.

Mostly though your daughter's prescription just sounds like the  
optometrist is being careful not to aggravate her nearsightedness.  
It certainly won't hurt, and might be important especially  
for kids to be concerned about that. But you might want to  
consider whether the bifocals will work for her -- does she normally  
look down for close work, etc.

You might consider Spectralite. It is light and lenses will be thinner than glass lenses of the same power. It has little chromatic aberration, not much more than crown glass. It is more expensive than polycarbonate and more brittle.

Actually, I do plead ignorance. I looked up 'eye' in the Microsoft Encarta Encyclopedia and they had a little animation of how the lens (note, not the whole eye itself, just the lens behind the cornea) works in focusing. They showed it flattening when the eye was focusing far and widening when focusing near. I had previously read (from several sources, Bates etc) that the ciliary muscle is in a relaxed state when focusing in the distance so I just came up with a mental picture of what and how my lens & ciliary muscles were doing. I'm glad to see that there are posts on other theories about how the eye focuses, because I wanted to open this up for discussion so I can educate myself!

Thanks for the info.. I'll read it over and then maybe post my thoughts to the list..

> In any case, I'd love to hear more about your views on the  
> Accommotrac. I had thought that it worked by looking at  
> reflections off the lens so it could measure the lens shape.

thats correct. It bounces an infrared light off of your lens (not sure how/why is skips the cornea) and measures the reflection 40 times per second. From this data it then computes a number and sound, corresponding to how your lens is focusing... the more distant your lens is focusing, the higher the number, and the higher the pitch of the sound. When my eyes are tired and I am stressed out, I can barely get higher than a -4 (note this is the accomotrac number - not related to diopters or anything...) when my eyes were fresh and relaxed, I've been able to get up to a +2, with occasional bursts of +3 (the therapist I am working with says he is able to get +5 numbers [he has perfect vision] with hardly an effort).

The trick is to be able to use the biofeedback to figure out just what it is you are doing to get those plus numbers. I usually try to visualize I am looking at something far away and it usually more or less works...

> I wonder how this relates to the Schachar view. I also wonder  
> how it reacts to any change in refraction of your cornea.

not sure what "increased zonular tension" means ... ?

I'll read up on the Schachar theory..

>

> Do you walk around with good vision at -4.75 or do you have  
> to "remember the tones" to clear up your vision when you  
> need it?

actually remembering the tones hasn't really done too much for me-  
I have only had 3 sessions on the accomotrac and it usually takes  
about 8 to start getting it.

I've noticed a slight improvement in vision almost every day, but  
I feel like the other therapy techniques are what are improving my  
vision so quickly as I am spending much more time and attention  
to them- especially now that I am seeing some improvement..  
I'm psyched!

I'll spend a good 30-45 minutes a days (spread throughout the day)  
doing palming, eye massage and blinking. That is the bulk of my  
self-treatment. I also am using the brock string & harts chart.

I'm also trying to be more aware of just how my eyes are doing  
throughout the day, taking care to look off into the distance every  
so often when doing close up work and remembering to BREATHE!

I'm following an approach very similar to Dr. Kaplan's vision  
fitness program.. using a slightly blurry prescription which  
stimulates my eyes to gradually "lock on" to the out of focus  
prescription. On my first visit to the therapist, I was evaluated  
to have "Accomodative spasm" - meaning that my focusing ability  
showed promise because it was all over the board (showing that  
I was able to at least change it) .. I was seeing 20/20 through  
my -6.0's and the docter decided to try some -5.25's  
on me after the accomotrac. I did a deep blink and was able to  
read the 20/20 line for a brief second. The -5.25's were  
a little rough at first, but plenty good enough to drive with-  
especially in the bright Atlanta sun. (of course I wouldn't drive  
at night with them.) I was noticing a definite improvement in the  
5.25's every day and after two weeks, the doctor measured my  
eyesight again and decided to drop me down to -4.75's (much  
to my surprise!)

On Sunday I went to Olympic soccer, glad to get a chance to focus  
far for a long period of time. I am not seeing in  
perfect sharp focus in my -4.75's, but after a yawn and deep blink  
(the deep blinks seem to work really well for me) everything  
would come into sharp focus for 5-10 seconds and I could see  
the players numbers on the players uniforms with absolute clarity

from the upper deck of the stadium (Legion field, Birmingham AL.)

This was a great feeling given that my prescription is already over 1 diopter lower than just 3 1/2 weeks ago!

Tommorow I am going in for my fourth session and I'll see what happens this time.... Not expecting or hoping for another drop in prescription - just trying to "be" as Dr. Kaplan puts it.

>

> How did you find your accommotrac practitioner? What kind  
> of practice does he/she have?

After reading about the Accomotrac in a book called "20/20 is not enough" (by Dr. Arthur S. Seiderman and Dr. Steven E. Marcus, BTW - they do a much better job in describing how the thing actually works!) I decided to seek out one, so I went to the yellow pages under optometrist .. there were tons of listings (I'm in the Atlanta area) but only two with the magic words "Vision Therapy" I called one of them (Gottlieb Vision Group off of Memorial Drive 404-296-6000 for anyone who cares) and asked if they used the accomotrac.. I got a good vibe after talking to the receptionist for a couple of minutes and so decided to try it out ...

Dr. Gottlieb is a regular optometrist, who prescribes glasses in the traditional manner, but he is open minded about natural vision improvement and vision therapy- he mostly does the traditional vision stuff and there are several therapists (one of which is assigned to you) which teach you various visual techniques. The sessions are 1 hour, once a week (and its pretty expensive.)

The lead therapist told me I was a very good subject because I knew a lot of the techniques already (from reading books like Kaplans, Bates etc.) and that I had maybe a 3 week lead over people going in not knowing anything about vision therapy (I had previously improved from a -6.5 to -6.0 just on my own). They say that 8 weeks is a good rough measure on whether the therapy is going to be effective or not - the doc was quick to tell me that it would be unlikely that I would improve completely back to normal. I'm hoping to prove him wrong.

Hope I have not blabbed to much about this, but I am excited over my improvement!

A very interesting post!

Elena <[solusrex@soho.ios.com](mailto:solusrex@soho.ios.com)> wrote:

>have accumulated a huge amount of evidence of the way repression  
>of emotional release translates into unconscious muscle tensions that impair  
>various functions of our various organs.

I agree. But in the case of myopia I do have a contra-argument that I would love to see it successfully challenged. It has simply to do with time and its relation to the human psychic development.

I shall give as an example myself because I know this case best but this is with the understanding that MANY of the environmental myopes have followed a similar path, therefore this is the general case.

Nine tenths of my myopia I acquired between the ages of 9 and 17. More than half of it between the ages of 9 and 13. At these ages children, although they may be very bright, usually do not have the psychic of the adult and do not go through deep emotional upheavals or crises of the type I believe you (and I) have in mind now (sure, there are first love stories, some changes with puberty, etc, but again, not of the deep, transcendental type in question). I can vouch that despite my myopia, which, as is typical at those ages I didn't seem to notice or mind much, I had a happy childhood. Since 1st grade until 7th grade I was (1) one of the four total A scorers in the class (only one other of these being myopic); (2) The formal leader elected virtually unanimously for five years in a row from 3rd grade on when such organization started; and most importantly, (3) The *\*informal\** leader, frequently being the ataman of various gangs, initiator of games and pranks, etc.

This trend continued from 8th to 11th grade, even though I entered a

highly-competitive school. I was number one at the entrance examinations, scoring max on math and the highest on literature, beating out both boys and girls, even though the latter were somehow presumed to be better in literature than boys. I didn't finish 11th grade at the absolute top, though, having one A-, which put me in second place as there were several all A scorers, but still a good achievement.

At that age, 18, shortly before entering university, I had practically acquired all my present myopia. On the girls side, as this is especially important to teens, I also had success, and counting the first two years at university, I had made love to women on three occasions \*within ten\* minutes after we met, and that was not at orgy parties, just attraction at first sight. Not to mention other hits.

I am saying all this not boast or anything, in fact I am as humble as can be in accordance with the eastern philosophies into which I have been taught, but only to point out that I could have hardly achieved this if I were torn by emotional battles, if I had cronicly repressed my feelings, and if I felt as uneasy I as I unfortunately feel now.

This is not to say that I don't have supressed emotions \*now\*, I do, indeed I have a LOT, but most of this has happened AFTER the age of 18 when I had acquired all my myopia. I \*want\* to let them out but to do this profoundly in order to have the desired purging effect I'll have to pull out the rifle from the closet. First target will be the insane 20/20 seeing drivers on the roads. Seriously, from little (or big) things in the corporate office, to basic human relations, to various national policies, to world economic order I have a lot to be angry about.

To recap, I believe most myopia develops BEFORE the emotional maturity of the level discussed sets in. The primary reason for the acquired myopia is close work. I DO NOT dispute the detrimental effects on health that the emotional condition Elena described has. I object to it being put forward as the causative factor for myopia because of the time discrepancy I mentioned. Whether solving these emotional problems will lead to the evaporation of myopia I do not know, this would certainly help, but I am inclined to think that it is not the cure-all. But for adults I believe good emotional balance is a NECESSARY supplement to the grunt-bearing myopia-reduction process: adaptation to weaker and weaker lenses.

I don't have studies to back this with, but i'm pretty sure most of the significant identity crises occur during puberty. Socialization in the modern world is a pretty brutal process. The emotional self is alive and kicking from birth and this training is largely concerned with suppressing that information and molding oneself to established roles and responses. I know that during that time for me as well, i was enjoying myself, did well in school and sports and had many friends but also developed myopia. I have found several things in my adulthood (I'm 38) that are sources of stress that were introduced from the time i started to speak. These things are extremely fundamental building blocks of my worldview and not specific traumatic events that occurred to me. I think it's possible that as a child, the critical capacity is not developed and there is no way to identify and name the specific sources of conflict and also that these conflicts may not be problematic at first- only later after the trail is completely cold does one begin to put the pieces back together.

> I could have hardly achieved this if I were torn  
>by emotional battles, if I had cronically repressed my feelings, and if I

My guess is that the environmental factors; poor light, close work, etc.  
combine with the various stresses of life to cause the problem. And i agree  
that the physical work of changing habits is as necessary as the psychic  
work.

All of my eye exercise regimens that i have tried to set up over the years  
have had temporary success only, the old patterns reestablish themselves. I  
have been seeing the first really solid results for the past year strictly  
from picking away at discovering my subconscious motivations and really  
facing what i believe, want and \*AM\* (it's totally surprising what pops up)  
and find the motivations to eat right and exercise and do eye stuff have  
been falling into place as a preference and desire. I'm seeing much better  
and its not going away like it used to.

I guess it doesnt really matter how it got there, it's whatever works to  
get rid of it!

> and have corrected one error with another error?

:) Kind of funny the way you phrased that. No psychological analysis here right? Just Kidding. You know I am really happy about the results and yes of gaining back what I've lost a long time ago. It really is amazing how it all worked out and I can tell you all about it if you want. But I must admit I was very, very, impressed by the skills of this doctor, the smoothness and precisness of the procedure and the immediate results with no pain. Can you tell I'm still I bit extatic about it? Truly I don't feel any regret what so ever about "cheating" VT. Actually, I gave up on VT no so much because I did not believe in it... but because it required so much dedication and the results would have to come from a long term

commitment that I was not ready to take on. But down deep in my heart VT sounds like a great alternative to regaining your vision. So I still see it as that, an alternative but now I believe that it is not the only alternative. I was a bit apprehensive going into the surgery but after it was all said and done in about 15 minutes, I was impressed and all my fears were put away. Its amazing that I am writing this without any aid of glasses. I still employ a lot of the things I learned from VT, palming, sunning, eye formulas, attitudes etc.

Now the feelings that I was experiencing were interesting because they were feelings from my young adulthood, such as insecurities and fears of loved ones, career and future. Now, I have decided that I am going to deal with such feelings instead of pushing them aside and trying to understand what it was that I was trying not to see. Its just weird that these feelings are now coming back a couple of days after gaining my sight. It may be a coincidence but either way I am not going to take them lightly and will deal with them accordingly. The repercussions of not dealing with them are too great. Well this may be a longer spill than you anticipated, but its part of my new attitude of openness. :)

>  
> It is my unsuredness of the scope of effectiveness of VT that makes my life  
> hell and keeps me from going on with PRK.

Exactly, I guess if I think about it that had a great deal to do with my decision also. It was more my lack of faith even though all the "theory" behind VT seems to be right. Though decision... but as for me I was really sick and really tired of having that obstructed sight, it was really a pain having to mess with contacts and glasses. So simply, I don't regret that I had it done.

Right. I've decided to post also to the list, all in the spirit of openness and sharing, and some feel strongly against surgery but I will share anyway, we'll see if it makes it. ;)

Hi everyone.

It seems a lot of us are interested in teeth. I am too, but the purpose of this list is to talk about the EYES. Maybe someone should start an alternative dentistry mailing list.

Until then, there is a great web site out there that will lead you to a wealth of information on the poisons of fluoridation and fillings, the Preventive Dental Health Association...

<http://emporium.turnpike.net/P/PDHA/health.htm>

Following are the latest posts to I SEE regarding fluoride and mercury. I put them all together in one place so as not to crowd out the legitimate eye-related discussion.

You read stories in magazines from time to time about people who have been chronically ill and lethargic until they have all their mercury fillings removed. There was even one about a woman who was blind for 15 years, until her fillings were removed - something about short-circuiting. Whatever the reason, the removal of the fillings (if you believe what you read) brought

back her sight immediately.

I am lucky enough to only have 3 fillings, but I've opted for the white ones, even though they don't last as long and are more expensive (in England).

Incidentally - they say that even if you have a mouth full of mercury, it isn't necessarily the best thing to remove it all until it needs replacing.

I don't know about the USA, but in London you can get the level of mercury vapour in your mouth measured and compared with 'safe' levels.

Yum, amalgam. Another insult to the human body. I'd rather explore my options here. It wouldn't be at all surprising to discover that some folks have excruciating sensitivity to amalgam, what with body parts being connected and all.

Feeling kind of toxic,

-Tara

Mercury amalgam used for fillings has been implicated as a cause of Tinnitus (ringing in the ears) in some people. However, it's not a case of getting it removed and the T. going away, as sometimes this

has also caused Tinnitus, or made existing T worse. It's a tricky condition with many causes, or triggers. If there are any Tinnitus sufferers on this list who are unaware of it, check out the newsgroup alt.support.tinnitus. You won't find any instant cures there, but you will find plenty of supportive people and good advice.

Subject: Re: Fluoride; was: "TABLE SALT" IS POISON!!!!

IMO, this whole fluoride thing is another example of the "quick fix" syndrome. Because science has progressed on many fronts, those of us particularly in the industrialised west come to believe that science can solve all society's problems. Instead of the much more difficult (and perhaps economically and politically damaging) task of educating people away from decay-inducing foods and drinks, we tell people they can (literally) have their cake and eat it, with the help of the fluoride fix.

Glasses are an easier fix than VT, which is hard work.

Cycle Helmets and air-bags are an easier fix than curbing vehicle speeds and improving road-user behaviour.

And well blow me down if these fixes aren't also quite good for the economy, at least in the short term...

Fluoride was always simply too good to be true, and unsurprisingly, it turns out not to be true, or at least not as true as was once thought.

It's not too hard to imagine similar events some time in the future relative to genetically altered foodstuffs.

I'm not anti-science - quite the opposite - but it's as well to realise that it may have limitations, and announcements of progress should always be taken with a healthy dose of humility on the part of the sellers, and a healthy dose of scepticism on the part of the buyers.

Subject: Flouridation and filters

Mark asked about water filters:

My personal concern on drinking water is to remove the  
fluoride and chlorine, as well as toxins that the city did not  
remove, or were picked up on the flow through the pipes.

I believe that chlorine will reconvert to a gas and volatize off  
if left out for a day or so, which is what pet stores  
recommend to be done for tap water before being used in  
aquariums. Carbon filters can remove it at the tap or shower  
head.

Flouride stays in ionic form (like a dissolved salt) (I believe) and  
does not come out by letting water sit, or through carbon filters.  
According to literature from the Extension Service, reverse  
osmosis or distillation is about the only way to remove salts

like fluoride.

There are several reverse osmosis filters on the market. They work by forcing the water through a micro pore membrane. The membranes slowly degrade and need to be replaced periodically. A pre-filter can remove sediments and chlorine that can accelerate the wearing down of the membrane. These filters are slow, they run at drip speed, and so a collection device is usually included. They often need to be installed under a sink or on a basement wall. They can clean about 2-10 gallons per day.

I haven't seen many r.o. filters around. But I have seen one at Costco in their California stores, (but not their Montana stores). The price seemed good, I forget how much, maybe \$80 to \$120. Several years ago I bought a small faucet model from Damark, it worked for a while, but I haven't seen them available lately.

TRIVIA ON ORIGINS OF FLUORIDATION:

I read in Acres, USA that the idea that fluoride is good for teeth developed in an area of the country where there were high levels of phosphorus and calcium in the rocks and soil. The food grown in this region was also high in calcium and phosphorus, hence children growing up there had strong bones and teeth. Fluoride is a mineral that occurs with calcium and phosphorus, but is more soluble, and tends to be found in the ground water. Scientists found Fluoride in the natural water supply and assumed it was the Fluoride that caused strong bones and teeth, but others feel that it is the calcium and phosphorus in the crops. This wrong assumption led scientists to believe that adding flouride to water would give a health benefit.

I asked an M.D. about fluroide, he told me that among other things it was an enzyme inhibitor. Physical life is a series of enzyme reactions -- hence I don't want fluoride in my water. So my taxes put it in, and I pay again to take it out.  
hope this helps,  
scott

I've noticed the same effect underwater. Using goggles  
at the pool, I am sometimes surprised at the high levels  
of particles. I don't know if there's a good Newtonian  
model for the experience (the clarity, that is).

A driver with bad vision kills 3 girls.

>From UPI:

Copyright 1981 U.P.I.

May 18, 1981, Monday, AM cycle

SECTION: Regional News

DISTRIBUTION: Ohio

LENGTH: 408 words

DATELINE: NAPLES, Fla.

BODY:

Former Ohioan Rolland Slatzer, 79 and legally blind, surrendered himself Monday and was taken to a north Florida correctional facility to undergo tests to determine where he will serve his manslaughter sentence for the deaths of three young girls.

Slatzer was sentenced to spend from six months to five years in prison. He pleaded no contest to three counts of manslaughter for driving his car through a group of five children playing near an East Naples street. Slatzer said he did not see the children and thought he had only run over a garbage can.

In the Oct. 9, 1980, incident, Lisa Gant, 13, Renee Dodgion, 13, and Helen Oast, 12, were killed. Terri Gant, 8, was injured. A fifth girl was unhurt.

Slatzer entered no contest pleas to charges of culpable negligence for

the injury, and to two counts of leaving the scene of an accident.

Using a description of the car given them from one of the girls, police found Slatzer shortly after the accident at a nearby restaurant.

Although Slatzer said the girls were lying in the middle of the road playing marbles, others said the girls were near a tree at the end of a driveway when Slatzer's car ran them down.

A Collier County sheriff's spokesman said Slatzer was taken to the Lake Butler Reception and Medical Center north of Gainesville.

Tim Jones, a correction officer at Lake Bulter said Slatzer will be given a battery of educational, medical and psychological testing to determine at which facility the great grandfather should serve his term.

Slatzer will be eligible for parole after his examinations at Lake Butler.

'I think it's unfair,' Slatzer said of his sentence. 'There was no intent on my part to hurt those girls. I just didn't see them.'

Police said Slatzer, unable to obtain a Florida driver's license 13 years ago when he moved to Naples, returned to Ohio to renew his license without a visual examination.

Slatzer's attorney says he is legally blind, has hearing and heart problems and only drove the day of the accident because his wife was hospitalized. She has since died of cancer.

'Usually I didn't drive,' Slatzer said. 'Betty always did the driving. The only reason I drove that day was because I had taken her to the hospital and she turned the car over to me. I was just going to get supper when the accident happened.'

'I think the jail sentence was vital,' said Gary Dodgion, father of the one of the victims. 'He had to be punished.'

Stefan,

It's an interesting hypothesis, but I don't think it argues against the usefulness of body work for vision improvement.

Here are some rambling thoughts: I also seem to have had a childhood and adolescence successful in most areas that were important to me at the time and not so successful in some other areas. However, childhood is the time that we develop many of the patterns of behaviour that later drive us unless we do a lot of work releasing the energy. Sometimes I discover that an issue that seems to bother me a lot now, resulted from a small, almost unconscious behavioural choice I made some time many years ago.

I was going to say that emotional maturity is not germane to the discussion. Then I realized that as children, we make choices of behaviour and belief based on limited information. We begin to ossify ourselves if we grow older and fail to re-examine those choices and become more flexible.

Another issue is that releasing muscular and energetic stresses ought to accelerate one's emotional fluidity which should feed the process of vision improvement. Deep changes are more difficult if we are holding onto or defending a self-image out of fear or out of holding on too tightly to one way of seeing the world. If you pay attention, you can quickly identify where your body is tensing up in various situations. Others can help identify areas of bodily tension that we ignore

because it feels normal.

The relevance of emotional release through body work makes sense to me since vision is mostly an energy phenomenon (here I'm using a model that I know many will not ascribe to; mind is most adept at defending and maintaining the mirror of self-reflection; so powerful multi-verse vision should be a trans-mind phenomenon; OK you can wake up now.) and since all muscles of the body (as far as I have been able to discern) are connected. The body is full of energy and chronic tension (associated with emotional stresses as far as I've been able to discern) effects the flow.

>To recap, I believe most myopia develops BEFORE the emotional maturity of  
>the level discussed sets in.

It may be that we are too susceptible to conditioning at early ages (or not susceptible enough to good suggestions), thus our lack of "emotional maturity" may be what allows us to choose myopia.

Here are some more concrete images:

Recently, after hurting my knee swimming, I had a session with a swimming instructor. I thought I was a good swimmer, but I was happily surprised to discover various ways to make my strokes more efficient, more powerful, and more relaxed. Also, I've done some work on identifying and relaxing other areas of chronic tension. I didn't feel any deep emotions coming out, just joy at discovering a new level of relaxation in movement and ways to be more efficient in manifesting my body in space/time. I like to cultivate resonant models, so I look forward to finding ways to make my vision more efficient, more powerful, and more relaxed. For me, vision improvement is a whole body thing.

I'm all for people doing what they can to improve their vision, but NOT at the risk of harming other people. Haven't drunk drivers proved over and over again how this type of "The law's irrelevant, I'm the only one who can say if I'm safe to drive" logic does not work?

There are so many people killed on the roads each year, why don't we just say that this idea of 'below the legal limit' drivers driving without correction is (if not extremely reckless driving) at best debatable and therefore not worth the risk?

Come on, let's not get ourselves a bad name when all we're trying to do is help ourselves. Surely it isn't too much to ask for people to act responsibly and not endanger others in the attempt.

I thank everybody who has replied to my post.

Bill, I'm glad we're in agreement on the essential points -- I enjoyed your posts and I hope to be exposed to more of your ideas.

Mario, congrats on your successful operation. I may be a "hard-core VTer" but I certainly don't expect everyone to be as I am or do as I do. Hope you'll keep us informed, and get additional benefits from your Batesean vision skills.

Stefan, I will have to clarify a few points before getting down to a full-blown reply. By childhood emotional experiences, I mostly mean EARLY, like in very early, experiences, and I mostly mean REPRESSED memories, i.e. not the ones that you or I readily remember, but the ones stored away from consciousness (or even too early to be conscious). Otherwise, on the surface, the childhood/teenage picture you've described looks familiar -- been there done that, the best student, the formal/informal leader, sports achievements, off to a good start in college by being voted the prettiest freshman, etc.. Yet all these things are "me for others" -- "me behaving a certain way," "me succeeding by some outwardly imposed standards," "me getting approval from the outside world," and so on. They still don't prove anything about how one feels inside. There's a good reason for why so many people don't really KNOW how they feel inside -- they've been trained to assume that if they're well-adjusted and successful they're "entitled" to feeling good, and if they aren't they're supposed to feel bad. As adults, they seldom remember how to differentiate between what they actually feel and what they've been trained to feel. If it wasn't for this falsification, or if a falsified emotion was a good substitute for the real one, there would be no movie stars or millionaires or world-famous writers committing suicide -- but I do seem to recall a few names...

As for the time frame for acquiring myopia: an early emotional trauma (either cumulative or a single occurrence) causes some crucial changes in the functioning of the brain (the earlier it occurs, the more fundamental

are those changes), and they may take years to fully manifest themselves. For instance, early traumatic experience has been proven to be capable of changing the output of the growth hormone for life. This invariably screws up the immune system's functioning and all the delicate hormonal balance in the body. We don't know which substances specifically do the biochemical job of changing an emmetropic eye into a myopic one, but they may be (and most probably are) long-term factors that get into the picture covertly long before they become manifest. Btw, the genetic theory of myopia goes down the drain with this understanding.

Now for a full-blown reply. I have some notes that seem to already contain answers to some questions I could anticipate. Mostly I was just writing down some of my thoughts -- it often helps me clarify them -- and I wasn't sure I was going to post this particular piece of speculation to i\_see, therefore I didn't do any self-censoring. So anyone who feels that my opinions are too strong or offensive, please accept my assurance that there's nothing of the order of a personal attack on anyone contained therein.

=====

The changes in my vision came inseparably connected with changes in my thinking and my emotional status. At some point, I abandoned (lost?) much of my habitual control over feeling and expression and just let it all take its course, watching with a modicum of detachment how the first layer (excitement and hope as VT brought its first fruits, and some arrogance too -- "see what I can do!" and some unexpected "mentor's" overtones -- "I'm the one who knows the way!..") shifted to reveal the deeper level of feeling (anger! even rage! what did "they" do to me, how did "they" get me into this myopic mess in the first place?), only to be replaced by a host of other, deeper still, emotional realizations. That anger, for one, is fear in disguise ("they" can do things to change me, "they" shape my being into what "they" want it to be... and I don't even know when it's happening, I change in order to conform, I AM the product of this change... which is, whatever it is, however successful and well-adjusted to THEIR requirements, not the real me!). It only sounds paranoid if one stops right there -- but I followed the general rule, which was to ask the next question, rather than dismiss something I'd arrived at as "paranoid" or "speculative" or "subjective" or whatever. So the next question was, who are "they," exactly? And who is the "real me," for that matter? I only seemed to know one thing for sure about this alleged "real me": it's someone with perfect vision. So whatever happened to change this natural reality into its myopic distortion was a violation of my right to be myself.

Whatever/whoever it was had built itself into me, into my very own physiology, into the shape of my eyes and the way they see; and knowing that THAT was my myopia -- an alien thing, an "act" of conforming to someone/something else's requirements superimposed on my "real" functioning, it was only natural to infer that it was reversible, as long as I could correctly pinpoint the "villain," the thing or process responsible, and

eliminate it. Easy to say, one may think, where's the time machine? Whatever happened happened in the past, so how do I reach it from the present?

We are adults, to varying extents successful in our adult endeavors, busy solving our adult problems, enjoying our adult pleasures, and fulfilling our adult responsibilities; that's what we all think. Whatever happened to us, around us, and within us in the remote past, in early childhood, in infancy, seems to have nothing to do with our present joys and sorrows. But the thing is, the very concept of the "past" -- and the concept of time as such -- is the product of a late evolutionary acquisition of our human brain, the layer on top capable of conceptualizing. That's the part of us that can differentiate between "past" and "present," "then" and "now," "childhood" and "adulthood." The major part of our brain, and in particular its limbic system, the home of the "feeling" mind, can't do that. For the major part of our brains and all of our bodies, memories of past experiences is what's happening to them right now, they are physical, physiological patterns of functioning, not abstractions. Every experience creates an ORGAN in our brain, a tangible, physical organ comprised of a certain number of neurons connected in a certain way, excitable in a certain way, functioning all through our lives. In this (very real) sense, the part of you that can read is an organ; ditto the part that can ride a bicycle. And, unfortunately, the part that has gleaned from your early interactions with the world that you have to be something OTHER THAN YOURSELF in order to be accepted and loved and taken care of -- more polite, or more quiet, or less demanding, or smarter, or faster, or more self-confident, or "the best in everything" -- that part is an organ, too, and it does to certain systems of your body exactly what the part that can ride a bicycle does to the muscles responsible for the actual task: it tries to makes them adjust and perform in a certain way. Unfortunately, however it goes about it, this "certain way" is bound to be the unnatural way, because its task is to replace the natural way you are.

Forgetting all about these "replacements" of the way you really feel with some ritualistic enactments of someone else's idea of the way you are supposed/allowed/expected/encouraged to feel; having no idea of their nature and their very existence; doesn't make the real thing go away. One can forget he or she has a heart or a liver -- with no consequences for the functioning of those organs. Similarly, one can (and does) forget his/her early childhood experiences, with no consequences for the functioning of the organs in the brain created by those experiences. They just go on working, transmitting energy from the bottom to the top of the brain, "moving" the conscious layer the way the ocean would move a splinter floating on its surface. This is what the actual "map" of energy distribution in the brain looks like: the top layer is "rocked by the ocean" underneath.

Now imagine that this splinter is capable of conceptualizing, of thinking "rationally," but has no idea that the ocean exists. Simply has no conscious concept of "the ocean," or of any "underlying energy source." How

would it account for its own movement? Invariably, it would come up with the concept of "free will." It would decide that, since it moves (thinks, makes decisions, etc.), it IS the source of the motion. It would be proud of its "own" achievements whenever the direction of its floating coincided with its "conscious decision" to float in a certain direction. It would become depressed if, for some reason, it were unable to float where it "wants to," if mysterious obstacles between its "will" and the actual direction prevented it from being "free." The "mysterious obstacle" would be the ocean of course, the expansion of energy wide and deep and NOT EVEN CAPABLE OF BEING INFLUENCED by the activities of the splinter, no matter how "dedicated" or "single-minded" or "courageous" or "smart." But the splinter would go on analyzing or modifying ITSELF in order to come up with a solution.

Conscious activity is activity unaware of its energy source. The real outcome of this activity -- where the splinter will float, where an individual life will float, where the human race will float -- is determined by the activity of the energy source.

After seeking high and low for a year, I think I've theoretically solved the riddle of myopia -- and hope I'm on the way to solving it practically -- by integrating into my own understanding the ideas of Arthur Janov; his predecessor, Wilhelm Reich; his on-track (though in a weaker dilution, and shamelessly plagiarizing) followers, J. Konrad Stettbacher, Alice Miller, and Janet Jenson; and some Oriental traditions that view human body/mind/spirit non-dualistically. The above-mentioned sources aren't concerned specifically with myopia; however, my old belief that myopia is a physiological condition brought about by emotional events fit in well with their assumption that all disease, not excluding the "organic" kind, is psychophysiological in nature. Traditional psychology deals with human thinking and behavior, while traditional branches of (Western) medical science deal with organs and systems of the body; I humbly submit that the distinction is false in every single case. The whole symptom-based division of human conditions into "mental" and "physical" and "psychosomatic" is dead wrong. It's not "partially" wrong -- it's wrong in its entirety; medical science is a make-believe science resting on a false premise.

Medicine as we know it is not only counterintuitive and impersonal and cold and uncaring and inefficient and outright cruel; what's worse, it's going nowhere, and no amount of compartmentalized achievement in any given field will ever change the fact. It deals in unrealities. The only reality is precisely what it refuses to deal with: a whole human being -- sick as a whole, well as a whole, normal and real as a whole. "Myopia" is a term for one possible manifestation of the "something is wrong with the whole" condition. So is "diabetes." So is "schizophrenia." So is "cancer." So is "addiction." They are symptoms; distinguishing and investigating them separately from the whole (no matter how deeply) is an act of scientific irrelevance. What's relevant (and ignored) is the fact that they are totally integrated into who "has" them, or, rather, who "is" a lot of things

intertwined with that thing. Each and every one of these symptoms is a "biopathy," to use Reich's term; or a "psychophysical acting-out that replaces suppressed feelings," to use Janov's concept. Without dealing with the whole, mind-body-spirit-tension-repression-defense-pain-pleasure-fear-joy-all-things-human, none of them will ever be resolved. After four centuries of "scientific approach" and several decades of its alleged triumph, where's the goddamn cure for a common cold? Nowhere, and will never be found. Scientific approach (dismantling the whole, naming the parts, and eventually forgetting that a label and the actual phenomenon are not the same... "myopia," for one, is a label which contains NOTHING of the actual experience in it, whereas the real, subjective experience of myopia is NOT a verbal/symbolic expression of anything at all), the tear-it-apart-in-order-to-understand approach to a non-scientific, "non-tear-apartable" entity (a live human being, not a walking collection of labels like "gene" or "cell" or "rotten mood" or "outgoing personality" or "toothache") will never be successful, ever, in any field. There's never been a scientific cure for anything. Alleviating (repressing) some of the artificially isolated symptoms, which is the only thing it's capable of doing, is a trade-off: you shut it down here, it will re-emerge there, you kill your pain with a painkiller and it will do what a "killed" thing is naturally good at doing: turn into a corpse. You'll walk around with all those corpses of your repressed feelings disintegrating in your body/mind/spirit -- forever.

The "Eastern" cure is as prone to forgetting the whole as the "Western" -- the difference is just that they forget different things about it. The most "relaxed" and "aware" splinter floating on top, in deep meditation, with palmed and refreshed eyes, still can't relax the raging ocean underneath. It may be able to meditate itself away from the ocean, away from the underlying reality (maybe into an "alternate" reality for all I know), but it can't meditate the ocean into disappearing. No practice and "training" and exercise alone will do either; whether the eye muscles are relaxed or "trained" won't change the fact that they are an embodiment of the classic muscle block of repression; they contain the repressed feeling in their structure, and there's no changing that structure without releasing and experiencing the feeling. THAT will discharge the circuit in the brain that keeps the spasm in place. Nothing less will do the trick. The incredible pain my eyes felt during the first months of clear flashes was not the pain of "a muscle doing sit-ups;" it was the pain of feeling what had been blocked out of consciousness. The tears that accompanied it were not a mechanical discharge; they were the tears that I suppressed years and years ago. They had to be held back then, and the method is, invariably, suppression of feeling, which starts in the brain and winds up as an electrochemical command to the muscles that actually perform the physical act of suppression. The translation of "e-motion" is "motion toward the outside," and human emotions originate in the universal biological language of expression -- every live creature on Earth expresses what it feels, be it

the most primitive pain/pleasure reactions, as "motions," not as "inner" events, not as rationalizations/intellectualizations. You can sit back and intellectualize without lifting a finger -- but to stop a natural emotion from being expressed, to stop the "motion toward the outside" of a basic natural reaction, one needs to involve a hell of a lot of muscles in the act. And they never stop doing it, for the initial inhibiting command -- "suppress! here's an impulse, here's an adequate feeling you are supposed to feel given this particular stimulus, but don't you dare react to it! do what's necessary to stop it from being released outward!" -- THIS COMMAND HAS NEVER BEEN REVERSED. Hundreds, thousands of such nonverbal commands have never been reversed. They are interwoven with the fibers of our muscles, all through our bodies. They still govern the way our organs work. They still release the ruling hormones, still transmit, electrochemically, their eternal message. Suppress. Don't feel. Block. Shut away from consciousness, forever.

Hypnosis or "positive thinking" won't reverse those commands because you can't reverse a nonverbal message with a verbal message: it isn't backed up with enough energy. The amount of energy your brain uses up to inhibit feelings is too great to be released by an "uninhibiting" verbal idea, energetically infinitesimal compared to the underlying process it's up against. The organs involved respond to their own language, to the universal biological language of feeling. Mechanically performed exercises for the muscles of any kind won't work either, because they contain the movement but not the accompanying feeling, i.e. part of the message but not the most essential part; the most essential part is the "source" of the inhibiting message, its precise emotional MEANING, not the activities of the muscles that are merely obeying it.

Time doesn't exist in the domain of your inner brain. You're still suppressing those tears you had to choke back ten, twenty, thirty, eighty years ago. This very second, that's what you're still doing. That's what a certain part of your brain is busy doing. That's what your muscles are doing. Always. All of them that were ever used to suppress a natural movement, a cry of pain or indignation or pure need. All the impulses to reach out, to cry out for love and understanding and against cruelty and indifference, for all eternity, are being counteracted by impulses to suppress the sound and the motion born of a real feeling, forever circumvented into muscle spasms that had stopped them from being released. Myopia is a garden-variety muscle block of repression, something that has stopped the feeling when you were denied an opportunity to express it -- time and time again. To even express it to your own consciousness, which would amount to consciously understanding what's happening and integrating your own feeling into your consciousness, rather than letting it govern you without your ever knowing what it is that makes you tick in a certain way. Maybe you were too little for that. Or maybe the feeling was too hopeless, too unbearable to face without falling apart. So repression of feeling is a defense of course. At some point, it served the purpose of preserving your

sanity, because integrating the feeling into your consciousness at that time would have flooded it with more pain than you could possibly take. Because you were too little, or because the feeling was too cruel.

It happened long long ago. It is happening right now. It is outside time. Time, a conscious concept of yours, floats on top of a frozen wave of frenzy. That's what the real, tangible energy of a repressed feeling is: a frozen frenzy in your brain and in your body. You can't feel it because the thing that's frozen is feeling itself. Release it -- and what you feel is pain. Until it has been felt it can't be released; until it's released it can't unfreeze the muscles.

My better vision came at a price. A number of very near and dear illusions, the important ones, the ones that have shaped my perception of myself and of some "crucial" people and events in my life as well as in the larger world, came crushing down at the onslaught of clarity. Another confirmation of the essential sameness of our perception, feeling, thinking, and physical functioning. From the start, I couldn't decide what term would appropriately express the idea of this sameness. At one point, I was almost tempted to call myopia a "neurotic" condition, but didn't of course because the word has such unpleasant connotations and in fact is an insult in the guise of a medical term; but I felt that I needed a term that would express the sameness of what primarily manifests itself as functional difficulties (like myopia or stammering or impotence) in some people, as behavioral inadequacies in others (like addictions or criminality or the neurotic need to "prove oneself" over and over again, to overachieve, to rely on the perceptions of others for one's concept or self-worth), and as organic complaints (like cardiovascular disease or arthritis or cancer) in still others. The term was supplied by Janov: unreality. Regardless of the course repression has taken in an individual, organic or functional or behavioral, the outcome is always the same: its victim is unreal. Severed from his or her real feelings, which are replaced by surrogate activities or organic complaints or functional insufficiencies, this person is an illusion, living and breathing unreality. The very awareness of this fact is what our defense mechanisms are busy hiding from us. When some of them are removed, it dawns on you that you've never been yourself -- nobody ever let you. The plight is quite universal. You don't have to be subjected to some extreme, headline-type abuse; all you have to do to be thus deprived of yourself is be born to ordinary civilized parents, in an ordinary society of any type, in a world screwed up phylogenetically way before your birth, bound to screw you up onthogenetically no matter what you do. Hidden cruelty in child-rearing is your human heritage. In this respect, East and West match each other and don't differ a lot, although some Eastern methods of alleviating the universal results of the inherently cruel upbringing seem superior to some and Western, to others.

Is it worth it, coming to realize -- not intellectually, but with your whole being -- things like these? It can't be minor, it's an all-or-nothing

realization. It can do things to your life. It can demolish your values and goals just like that, the real you suddenly awake amidst a crazy make-believe, not knowing what to do next, not wanting to fit in anywhere where things are this way, not seeing anywhere where they aren't. Is it worth it?.. Anyone can decide for himself or herself. Improving myopia is increasing the real you and decreasing the unreal you in a lot more ways than what directly pertains to visual acuity. Is it worth it to be real? Far as my present understanding is concerned, there's nothing else worth living for. Although for someone else, quite plausibly, some kind of acceptable unreality will do, and acting-out and getting symbolic rewards for symbolic achievements (be it money or prestige or success or importance or power or whatever is out there that is essentially NOT A FEELING but something you replace it with, for lack thereof) will substitute for what's missing just fine.

Not for me. A whiff of reality makes all unreality stink. Can't help it. I was born to be real. I think everyone was, but I can't make "everyone" real, nor will I try talking "everyone" into wanting the same thing that I want. It's difficult and I don't quite know how to go about it and it's got to be resolved between me and me. The dispute between you and you is, similarly, none of my business.

But, hey everybody, I just wish for the real you to prevail.

Elena

I will be able to!

Actually, this is something I was wondering about; is progress usually "linear"-- or does one typically improve faster the worse your sight is but slower the closer you get back to normal?

His reason for saying this was so that I would not have un-realistic expectations about what VT could do for me. I did not like the negative attitude and I countered with "on the other hand nothing is impossible." He agreed with this.

If you don't believe you can do it, you are setting yourself up for failure.

A filter, designed and produced by a Nuclear Physicist (?), marketed as GE II by General Ecology is claimed to remove virtually everthing (except water, of course) ..including the halogens (chlorine, fluorine/ fluoride), heavy metals, bacteria, etc. It is also claimed that the filter is used by major airlines, the U.S. Armed Forces in the Gulf War, and other major organisations. They also claim favorable analytical tests certifications by reputable international centers. The filter is a bit pricey, but if all their claims are true??..

You may like to read more about them, and make up your own mind, at:

<http://www.concentric.net/%7E1pwp/>

David Matanjun.

P.S. No..I am working neither for the fluoride industry nor for General Ecology. As a health-related scientist, I believe we should share all available information for the benefit of everyone and anyone who care to make an informed decision..

Why won't you be able to get back to normal? Does this imply that people with a small degree of myopia won't be able to improve as easily/at all?

Caroline

No definite answer to that i can offer. My experience is that the VT has  
been effective, but not completely\_successful. My strong belief is that the  
flashes of proper relaxation/functioning are temporary because the cause(s)  
of the spasm are still present. the external exercises are essential for  
me though, the feedback from what that work generates helps identify  
success on the other end. the bad habits of viewing are to be fully  
discovered and could possibly drive the process, if driving the process is  
actually possible.

Re : Accommotrack

- *Subject:* Re : Accommotrack
 - *From:* Massimiliano Stolfa <mstolfa@rtmol.stt.it>
 - *Date:* Thu, 25 Jul 1996 09:26:10 +0100
-

I have read the debate on the use of the accommotrack with interest and from expert of the sector, I am a regulate Behavioural Optometrist, I would mean anything in worth. Different years ago, five for the precision, I began to use this tool inserts it in my clinical practice like visual re-education for the recovery of the functional myopia. After different time and much personal experimentation I noticed that the accommotrack and similar tools, don't measure the accomodative value of the eye at all (in fact it marks positive values also with afachics) and that has also shown from subjects able to accomodate voluntarily. The variation of the sound depends exclusively from the big or small shine of the reflected ray and therefore from the transparency of the lens, of the vitreous and from the retinic reflection. That is correlated to the attention and to the concentration of the subject. The cost of the use of this tool (for the subjects) has pushed me to continue the searches and together to other two collegues of mine I have patented and experimented a method that before block the myopia, fights it and confers a visual natural acuity (without glasses) superior to what was had in departure; but without eliminate the physical myopia of the eye (because if an eye is longer than another, anything can reduce it without surgery). That could seem absurd, but it is the reality. This method is called S.C.S. Method. The S.C.S. Method eliminates astenopia caused from a wrong behavior at close distances (reading, writing, computer, etc.), it increase the visual natural acuity, it reduces the power of the necessary lenses to have a visual acuity of 20/ 20 and, important thing, it stabilize the results at the end of the period of training (this only with the accommotrack is impossible). All this staying at home going to the Optometrist few times for some checks, without excessive expenses and without strange tools. For have ulterior information you could view my home page to the URL: <http://www.webcom.com/visionet/max.html> or to the general

index to the URL: <http://www.webcom.com/visionet/welcome.html>. All that because I am a promoter of the natural, simple and economic visual- behavioural techniques. Our organism, if direct in a good manner, it is able to enormous potentiality. Excuse for my bad English and I am waiting for any other our visual problem or question.

Elena, it was really very interesting to read your follow-up post and I concur with many of the things you said. In essence, you elaborated on your first post, with which, you will recall, I agreed with the therapy you proposed, namely, with the inclusion of 'emotional therapy', emotional release, being yourself, or however you may wish to call it, in the myopia reduction process.

My objection was on the etiological side, that myopia is **caused** by emotional imbalance, something you stated again,

>my old belief that myopia is a
>physiological condition brought about by emotional events fit in well with
>their assumption that all disease, not excluding the "organic" kind, is
>psychophysiological in nature.

and to which I think you've gone too far. You have fallen victim to Russo's first fallacy of reasoning, the 'cave fallacy', i.e. assuming that what you think is true about yourself is the universal rule.

A few basic facts. Myopia is much more common among the more educated people and among those who spend a lot of time doing close work like clerks, etc? About 60% of Southeast China's population is myopic, about 80% in Singapore, and these nations are known for their demanding school systems. Frances Young's study of Eskimo children found an unequivocal relation between their enrolment in western style education and the sudden occurrence of myopia (more than 50%), while virtually none of their parents were myopic. Are you suggesting that all these people have had seriously traumatic childhoods or have suffered from child abuse (sorry, couldn't help thinking about this)?

I think I take a broader view when I observe not only myself but other myopes (in abundance). I have talked on the subject with people ranging from top executives of Dow Jones-10 companies to ordinary stockbrokers to various 'desk clerks' to grassroot librarians to PhD students to artists from all arts, and from another angle, to people from more than 20 countries. Believe me, I have received very different answers, like 'never notice it, I just don my glasses in the morning', to 'weaker glasses make your vision deteriorate' (this from a -5.0 D Chinese).

If you think that all disease has an emotional root, how would you explain a ruptured cornea following a car accident or a broken limb, for example? If these do not qualify as 'diseases' so that they can fit your theory then be sure than I will say that myopia doesn't either. If they do, then I am bracing for a twisted explanation. Like atheletes who develop their bodies in a specific way in response to particular exercises, we, too, have trained ourselves into myopia mainly through close work. However, I do allow for myopia in some cases to have been caused by purely emotional reasons, having dealt with Freud, Carl Young, and Adler in past years as well as having own observations. Without having any data to back this up, my hunch for myopia causes distribution is as follows: 90% environment and genetics, 10% other (psychological causes belong here, as well as others like whiplash injury, brain damage, etc, that cannot be classified as environmental in the sense of 'close work').

As I emphasized in my previous post, 'emotional therapy' is a NECESSARY part of the vision recovery and I look forward to your posts as you have shown an incredible insight into this sphere.

Stefan

I wonder if this fits in with what other people find. Is VT of no permanent use unless the accompanying subconscious work is also tackled? Or is this just if the cause is mainly emotional rather than mainly bad habits?

Bill - Anything special about how you discovered your subconscious motivations?

From: Bills
To: stefansi; i_see
Subject: Re: Muscle tensions (was Re: jaw relaxation techniques)
Date: Tuesday, 23 July 1996 6:05PM

All of my eye exercise regimens that i have tried to set up over the years have had temporary success only, the old patterns reestablish themselves. I have been seeing the first really solid results for the past year strictly from picking away at discovering my subconscious motivations and really facing what i believe, want and *AM* (it's totally surprising what pops up) and find the motivations to eat right and exercise and do eye stuff have been falling into place as a preference and desire. I'm seeing much better and its not going away like it used to.

I guess it doesnt really matter how it got there, it's whatever works to get rid of it!

Stefan,

thanks for helping me shape my arguments by disagreeing with them. One can never overestimate the value of a thoughtful opponent!

>My objection was on the etiological side, that myopia is **caused** by
>emotional imbalance, something you stated again,

>

>and to which I think you've gone too far. You have fallen victim to Russo's
>first fallacy of reasoning, the 'cave fallacy', i.e. assuming that what you
>think is true about yourself is the universal rule.

Exactly. And because I did it "with my eyes open," knowing precisely what I was doing, rather than falling into that cave as the result of taking a precarious reasoning step, I found not only those "shadows on the wall" there but also a lot of hidden things not visible from outside the cave, things that I would have missed if I followed the linear path of reason. Guess what -- you get out at the other end of that cave and the path of reason leading to the universal rules is still there, only you realize you've taken a shortcut and saved yourself years of travel!

Btw -- this is not to pick on you, I write in a freakin' foreign language and occasionally can use a spelling wake-up call myself -- it's not Russo as in Russo-Japanese war, it's Rousseau as in, Jean-Jacques. I happen to know why you wrote "Russo" only because we have, in this case, some subjective reality in common: I'm also prone to back-transliterating some foreign names from my native Cyrillic version. I bet nobody understands the precise reason why one would use this particular spelling unless he/she knows a very specific factor -- the Cyrillic version. The reason behind your spelling is unobvious to others, hidden from others, yet absolutely, unquestionably clear to you, right? That's the way all subjective truths

work: they are incontestable. The only problem is arriving at them, for so many are hidden not only from others but from ourselves.

>A few basic facts. Myopia is much more common among the more educated people
>and among those who spend a lot of time doing close work like clerks, etc?
>About 60% of Southeast China's population is myopic, about 80% in Singapore,

>myopia (more than 50%), while virtually none of their parents were myopic.
>Are you suggesting that all these people have had seriously traumatic
>childhoods or have suffered from child abuse (sorry, couldn't help thinking
>about this)?

Yes.

Yes I do think that education can be and is and has long been a form of institutionalized abuse. A "demanding" school system is all the more abusive. This one, not from a personal perspective of someone to whom books didn't come easy -- I may have mentioned that I had photographic memory in pre-myopic years and to study meant to take a picture, a few minutes worth of homework for each subject can hardly qualify as abuse in my case. But there were other kids who had to spend hours doing the same amount of work, and for them, it was abuse. Not letting them develop at their own pace, setting a universal pace for non-universal, different, one-unlike-the-other kids, is abuse. If it takes the form of close work -- well it's close-work abuse, and if it takes the form of having to compete, being shamed for poor performance, ridiculed for stupidity, threatened with disciplinary action, warned against a bleak future, and instructed that they can avoid THIS kind of abuse by doing more close work, then ok, we may assume that it's close work that's to blame -- unless we notice a not-so-subtle logical fallacy in this kind of reasoning. For me, personally, the abusive part of education was to have to sit still in class and pay attention and get bored out of my mind. Thousands of hours of movement/thought/meaningful experience deprivation: cumulative trauma, however you slice it.

>I think I take a broader view when I observe not only myself but other

>me, I have received very different answers, like 'never notice it, I just
>don my glasses in the morning', to 'weaker glasses make your vision
>deteriorate' (this from a -5.0 D Chinese).

None of these answers answer anything. The thing about myopia is, what's making you myopic is hidden from you by definition if it's an unconscious defense. It's a process whereby your clear understanding of your emotional circumstances decreases, not increases. It's similar to every other defense in this respect: their role is to NOT let you understand what's really happening. What you get for answers is what people were told to believe by their mother or their optometrist (the -5.0 D Chinese must have picked an especially lousy source of information). You would have to go BEYOND defenses for the real answer. Something that often fails even in deep psychoanalysis, and certainly can't be done in a casual conversation.

As for "never noticing it": do you know that, "for reasons unknown to science" (but a fact picked up in bewilderment by statistics), moderate/high myopes have life expectancy about the same as alcoholics -- 4 to 7 years shorter than the general population? Looks like me and others on i_see haven't called minus glasses an "addiction" for nothing. So... they never notice it in the spirit of, "I don't have a drinking problem -- I only have a problem when I can't get a drink!"

>

>If you think that all disease has an emotional root, how would you explain a >ruptured cornea following a car accident or a broken limb, for example? If >these do not qualify as 'diseases' so that they can fit your theory then be >sure than I will say that myopia doesn't either. If they do, then I am >bracing for a twisted explanation.

Have I ever given you one? :-)

An accident is an accident. I have nothing to say about accidents except that, apart from some of them being a natural toll we occasionally pay for being flesh and blood and non-invulnerable, there's too many cars and not enough public transportation. That 79-year-old manslaughter culprit from a different thread who was legally blind, deaf, hadn't driven a car in ten years, and had to take his dying wife to the cancer ward, may have opted for a bus if he had a choice. (This is not to revive the driving w/o glasses argument -- matter of fact I don't do it and wouldn't recommend it -- but just to check how observant we all are, here's a pop quiz: which one looks like an endangered, disappearing species, rules/regulations or accidents? I won't get into an argument -- just suggesting this as an exercise in clear vision.)

> Like athletes who develop their bodies

>(psychological causes belong here, as well as others like whiplash injury,

>brain damage, etc, that cannot be classified as environmental in the sense
>of 'close work').

Here's mine (a preliminary estimate):

- 1)For low myopia: a combination of low-impact emotional factors (abusive schooling), poor environmental conditions, nutritional deficiencies, and iatrogenics ("correction" with minus lenses) accounts for 99% of all cases.
- 2)For moderate/high myopia: moderate/high-impact emotional factors (biochemical/hormonal developmental changes in response to subjectively/objectively traumatic emotional experiences of early childhood, starting in infancy), aggravated by all of the "low myopia causes" mentioned above: 99% of all cases.
- 3)For extremely high, destructive, "malignant" myopia: high-impact emotional trauma (either traumatic birth, or severe early abuse or neglect): 99% of all cases. Other possible eye-related manifestations of this kind of trauma: ocular migraine (originates in excessive pressure on the head and face during birth, worse on the side pressed against a physical obstacle; a migraine is structured as a visceral memory of this event that keeps re-emerging either in response to certain specific triggers, or spontaneously. In one typical case, a nurse was pushing back the baby's emerging head for twenty minutes because she wanted to wait for the doctor, who was running late, to perform the delivery. The baby grew up without the slightest idea that this ever happened -- all he knew was that as an adult, he suffered from debilitating migraines for decades. They disappeared after this experience was remembered, re-lived, felt, and integrated into consciousness.). Some cases of glaucoma; some cases of amblyopia.
- 4)Genetic myopia of varying severity (usually part of complex syndroms, chromosome aberrations, congenital brain/eye defects, etc): 1% or less.
- 5)Myopia due to accidents: no idea. Probably rare.

>
>As I emphasized in my previous post, 'emotional therapy' is a NECESSARY part
>of the vision recovery and I look forward to your posts as you have shown an
>incredible insight into this sphere.

Thanks. Neither do I argue the importance of other approaches commonly known as VT, but my point is, myopia, like any chronic condition, will be influenced by many factors and some will temporarily relieve it, while uprooting the cause may cure it. I agree that visual re-education is crucial since one has to eliminate not only the cause of myopia but the effects of one's eyes/brain/mind having led a myopic visual life, and of having worn glasses!

Elena

No guarantee here, but try searching within:

<http://www.blackwell.co.uk/bookshops/>

Blackwell's is said to have over 150,000 books in its stock, including a section on rare books. You can search for a book by author, title, subject, publisher or ISBN.

2. Alternatively you may like to try British Library's vast collection of 17,000,000 bibliographic records representing material in every printed language - ranging from the earliest printed books to most recent scientific papers. You may like to try to look for Jonathan Barnes', a British biologist, readable and level-minded book on the Bates method and read how he can now see electrical cables 2 kilometers away (?) with better than 6/6 vision.

3. Or you may like to search the massive New York Public Library :

<http://web.nypl.org/>

Elena has again shared some very insightful thoughts with us. The argument shapes out to be about the **relative weight** of close work vs emotional distress in the genesis of myopia, as it is now clear that we both agree about the causative power of the two factors.

However, we stand on the two extremes, Elena thinking that emotional factors are responsible for 99% of myopia cases and myself thinking that they account for less than 10%, with close work and genetics(=past close work) chiefly to blame. It seems to me that the ultimate solution could come from carefully controlled studies, but their practical feasibility is hard to imagine.

Shrugging off this somewhat bleak scientific intro I will hit harder on Elena's gaping logical flaws. I realize she is a woman or a lady but feminism/emancipation may have some negatives for some. I hope this will bring us closer to an "out-of-court settlement", meaning eliminating the need of a sci study.

>Yes I do think that education can be and is and has long been a form of
>institutionalized abuse. A "demanding" school system is all the more
>abusive.

Can't deny that school is an unpleasant experience for many and that it can be greatly improved. Fundamentally, though, acquiring knowledge is the most rewarding thing for me, and I should say to many other minds from Socrates to Newton to Hegel and beyond. I have had boring classes but by the time I had reached my junior year at university I was immune to the influence of professors whom I considered to be inferior in understanding. But straight to the point, my observation is that it was generally the more studious and conscientious pupils/students who became myopic and these usually did not perceive the schooling system as especially onerous. On the contrary, those

who couldn't stand still in classes, who would spend every free moment out with friends, they usually enjoyed good or better vision. Many of my grad school professors were *very* myopic but they really enjoyed what they were doing and are still national and world authorities in their areas.

Second, even more convincing argument. In light of the wholistic view to which we both ascribe, I assume you wouldn't deny the links that exist between species. How would you then explain that in numerous experiments with monkeys, chicks, tree shrews, etc., all animals confined to small spaces or fitted with minus lenses invariably became myopic? Obviously, there is no universal school abuse in these cases.

>>If you think that all disease has an emotional root, how would you explain a >>ruptured cornea following a car accident or a broken limb, for example? If >>these do not qualify as 'diseases' so that they can fit your theory then be >>sure than I will say that myopia doesn't either. If they do, then I am >>bracing for a twisted explanation.

>

>Have I ever given you one? :-)

>

>An accident is an accident. I have nothing to say about accidents except >that, apart from some of them being a natural toll we occasionally pay for >being flesh and blood and non-invincible, there's too many cars and not >enough public transportation. That 79-year-old manslaughter culprit from a >different thread who was legally blind, deaf, hadn't driven a car in ten >years, and had to take his dying wife to the cancer ward, may have opted for >a bus if he had a choice. (This is not to revive the driving w/o glasses >argument -- matter of fact I don't do it and wouldn't recommend it -- but >just to check how observant we all are, here's a pop quiz: which one looks >like an endangered, disappearing species, rules/regulations or accidents? I >won't get into an argument -- just suggesting this as an exercise in clear >vision.)

Well, this was an ellusively twisted one. No intelligent paradigm will have 'accident' as a primary concept. On a Macro level this is a question of mechanics and forces, and the eye elongates under the influence of various forces. On a Micro level We speak of Language(Syntax and Semantics), the Esthetics Principle, and the merging of the Conscious with the Unconscious, but the final result is the same.

>Exactly. And because I did it "with my eyes open," knowing precisely what >I was doing, rather than falling into that cave as the result of taking a >precarious reasoning step, I found not only those "shadows on the wall" >there but also a lot of hidden things not visible from outside the cave, >things that I would have missed if I followed the linear path of reason. >Guess what -- you get out at the other end of that cave and the path of >reason leading to the universal rules is still there, only you realize >you've taken a shortcut and saved yourself years of travel!

Many people claim they know better and have a farther look into the future and yet they speak differently. Who's to be trusted by the less clairvoyant?

As far as your spelling note goes, you are right, Rousseau is the right spelling, I knew it was wrong but the IBM server of the library I use to check names and other stuff had crashed at the time of my writing and I couldn't access it. And I didn't want to lose time surfing the web. Btw, taking a self-hit, I misspelled another name but it has escaped your scrutiny or your were graceful not to point it out. It is Carl Jung, Carl Gustav Jung, not Carl Young as I wrote, although young(English)=jung(German).

>I agree that visual re-education is
>crucial since one has to eliminate not only the cause of myopia but the
>effects of one's eyes/brain/mind having led a myopic visual life, and of
>having worn glasses!

This is a good statement and I stand behind it. Finally, Bill Stender may prove to be wisest when he said "I guess it doesnt really matter how it got there, it's whatever works to get rid of it!"

Vision Exercise for Two

- *Subject:* Vision Exercise for Two
 - *From:* Mark Jones <mjones@auscsmp.sps.mot.com>
 - *Date:* Fri, 26 Jul 1996 09:39:56 -0500
-

Last night, I was trying to go to sleep after a late-night workout, and I was struck by the following idea. It comes from reflections on body/emotion work, massage, and other threads of experience.

=====
A Vision Exercise for Two

Have your partner place his/her palms over your eyes.

RECEIVER:

Lean back against your partner and allow your partner to place his or her palms over your eyes. Breath deeply, relax your body, rest, feel warmth of hands, do nothing or enjoy meditation or awareness exercises. Be present and aware of any feelings or memories, or other impressions that come up.

GIVER:

Relax your body. Place palms of hands over partner's eyes. Be lovingly present in your touch. You can do one or more of the following awareness exercises to maintain a sense of connection:

1. At the beginning, and again at the end, breath in deeply from the stomach and hold the breath for a comfortable count, such as 10. Then release all the air and repeat 3 - 5 times. This will temporarily increase the oxygen supply. If you are comfortable with the idea, consider that it will increase the energy as well.

2. If you like, synchronize your breathing with that of your partner. After a while, try breathing opposite your partner.

Also, note any feelings, memories, or other impressions that come up.

AFTERWARD

Afterward, share impressions or feelings.

=====

Mark

Elena's Posting - Muscle Tension

- *Subject:* Elena's Posting - Muscle Tension
 - *From:* "Linda Lee" <llee@island.net>
 - *Date:* Fri, 26 Jul 1996 11:37:47
-

Elena,

I have read your last two postings carefully. I pretty much agree with you as far as you go, but i personally confer with Bill (fr.ALSO) who wrote that our beliefs create our reality. Yes, emotions are important, but IMHO, behind every emotion there is a thought that holds it in place. Something like, "i am at fault here because i am unworthy..." and i believe these thoughts are very carefully buried, perhaps metaphorically at a muscular level.

I did have a go at the exercise you describe, the wide-eyed terror face with very rewarding results. I was able to achieve an emotional release of a pain i didn't even know i had. I felt exhausted after the attempt and plan to continue.

I would like to know more about the exercises that address the jaw, throat and tongue muscles. I have looked though some yoga books myself but have been unable to find any. Can you point me in the direction of a few titles of books that are still in print? I was intrigued by your claim that your singing voice improved so i gave heavy yawning a shot today. And it's true, my windpipe was much less cluttered, more open. This is very good news for me because i am a singer.

Thanks for you help.

Linda

My apologies: I, inadvertently, left out the URL for British Library Online in my earlier mail (as per para. 2 below). It is, in fact:

<http://portico.bl.uk>

David Matanjun.

```
>Date: Mon, 22 Jul 96 15:27:20 EDT
>From: RBF41@CNSIBM.ALBANY.EDU
>Subject: Jacob Raphaelson
>To: I_see@indiana.edu
>Sender: owner-i_see@indiana.edu
```

```
>
>My grandfather, Jacob Raphaelson, wrote a book on plus glasses many years ago.
> Does anyone have any information on the book or on him? He died about 25 year
>s ago. Rich Felson.
```

```
>
```

```
>
```

No guarantee here, but try searching within:

<http://www.blackwell.co.uk/bookshops/>

Blackwell's is said to have over 150,000 books in its stock, including a section on rare books. You can search for a book by author, title, subject, publisher or ISBN.

2. Alternatively you may like to try British Library's vast collection of 17,000,000 bibliographic records representing material in every printed language - ranging from the earliest printed books to most recent scientific papers. You may like to try to look for Jonathan Barnes', a British biologist, readable and level-minded book on the Bates method and read how he can now see electrical cables 2 kilometers away (?) with better than 6/6 vision.

3. Or you may like to search the massive New York Public Library :

<http://web.nypl.org/>

4. Then there is this thing called the Electric Library:

<http://www.oplin.lib.oh.us/ABOUT/ACCESS/access11.html>

Peace.

The enjoyment of acquiring knowledge is separate from the schooling system.
Are you saying you enjoyed the pressure to make the best grade? enjoyed
those times when the material was suddenly opaque but the test was still
being given on schedule? And meditate honestly about the devices one
constructs to explain these factors, such as 'it's necessary to the
process' or 'we can't survive it if we whine about it', we look beyond the
smaller inconveniences to the 'greater picture' and suck it up and even
develop a 'taste' for pressure, (no pain no gain). But the theory is that
this pain didn't vanish, but was diverted and became bodily
stress/dysfunction. Don't get me wrong, the school is just an extension of
society, which is an extension of our collective belief system. I'm not
willing to move to a desert island to solve it, and a kid sure can't, so

how do we ameliorate the situation?

>

This sounds like patent abuse. It's not just 'school' that causes stress,
it just happens to be one common cage we all were put in.

> No intelligent paradigm will have
>'accident' as a primary concept.

Well i could give you the statistical rebuttal that these are exceptions to
the normal cause of myopia, but i KNOW you secretly want the twisted
explanation, so here goes:>

There is no such thing as an accident. The term will become archaic in our
not too distant future as science slowly catches up with reality and
endorses the fact that everyone creates their own reality. 'What goes
around comes around' will be restated with technical precision. I know this
theory makes people very angry to hear when for instance they or someone
they love has fallen victim to some horrible accident because the
implication is that they did something horrible to deserve it. But the
false concept of universal Right and Wrong is to blaim for that anxiety,
life is a series of trajedies and blissful solutions. This is the way we
like it! (direct all religious-specific rebuttals to my private mailbox
please:)

>

>>you get out at the other end of that cave and the path of
>>reason leading to the universal rules is still there, only you realize
>>you've taken a shortcut and saved yourself years of travel!

>

>Many people claim they know better and have a farther look into the future
>and yet they speak differently. Who's to be trusted by the less clairvoyant?

trust noone. "Success is your proof and courage is your armor". First
person research and individual conclusions and tangible results are the
ONLY way. Reading other people's theories and conclusions is only useful
to get ideas for your own research. Many people make a point of avoiding
other peoples conclusions in order to not 'pollute' their own research,

what happens when reading other well phrased theories is that they tend to create borders for thought and experiment, (prejudice). I don't really worry about whether one author or another is RIGHT, also i dont worry about whether I'M right, i don't even believe there is such a Thing as Objective Rightness. they are just so many words and are secondary to the real matter of generating maximum joy, which is where 'the rubber meets the road' as they say.

One quick recounting of a stress that went unnoticed for my entire myopia forming years. I am an artist, i've always been a good artist. But in my house and in my schools, art was a fun thing but not a serious thing. I always tended to go along with what my parents and teachers wanted me to do, which essentially meant that i never seriously considered being an artist. I was good at math so i naturally followed a science course and went to University intending to become either a biologist or something to do with environmental science. This worked alright, but in my second year i took an elective drawing class. I was way out front in that class and my teacher took me aside and started encouraging this side of me. I realized that i really enjoyed this and for the first time started thinking about it as a valid career pursuit. Now i cant imagine NOT following this course, but at the time it was a very difficult decision, informing my father of this was extremely stressful and i was not really given much support by anyone. Life is full of these types of situations, we are not encouraged to be 'different', in fact some people are beaten to death for it. Consider the plight of the average gay person, here's their very sexual preference and they cant express it without being ostracized (the universal and harshest punishment). Sure you can live with the repression of your preferred behavior, but you sacrifice a bit of your life with each of these decisions. Little things add up and start causing larger outward manifestations.

-Bill off soapbox;>

Myopia Statistics?

- *Subject:* Myopia Statistics?
 - *From:* Mary Marlowe <phishes@pbfreenet.seflin.lib.fl.us>
 - *Date:* Fri, 26 Jul 1996 18:58:12 -0400 (EDT)
-

In earlier posts, statistics were mentioned. Maybe someone knows the answer to my question: What is the percent of myopia in females? What is it in males? My guess is that it is higher in females, and I believe it is culturally induced. In cultures where downcast eyes are expected of both sexes, the numbers might be more even. The remark about limiting the distance research animals were allow to see brought this to mind...

I think there are other ways of being short sighted, too. One way I have been was to value (and rely on) my intellect, while denying my physical and intuitive skills. I did that because I wanted to belong, and because I came to not trust myself.

Mary Marlowe

I forgot to save the address of the person who just got the laser surgery. I have some questions for you. Prior to the surgery did your doctor tell you that you had other options for improving your vision and were these options written into the consent form you signed before surgery. Were you informed that myopia is more than just a visual acuity problem? That myopic eyes have more glaucoma, more vitreous degeneration and more retinal detachments? That the surgery would change your visual acuity but not your risk for these other problems? That research is going on now regarding the etiology of myopia and possible chemical factors involved in the stretching process? Meaning that if a mechanism, biochemical, for myopia is better understood, not only will we have this VT therapy, which is difficult, but there is a possibility in the next few years or more of a medical treatment to reverse myopia. A treatment that might not only reverse the visual acuity problem, but also reverse the stretch and thus perhaps lower the risk for glaucoma, etc.? Were you informed that there were many unanswered questions regarding this disease?

Hi Mary;

Just HAD to jump in with my new found 3rd year optometry knowledge!
According to my professor Dr. Septon, who has researched the epidemiology
literature on myopia prevalence and incidence, here is what I know:

- a. Females develop myopia at an earlier age, by 1-2.5 years (12.5 yr. vs 13.6 yr.)
- b. Adult females have a higher prevalence of any myopia (75.1% vs. 70.3%).
- c. Males and females have about the same prevalence of low myopia (3.00 D or less, 45.7% vs. 45.9%).
- d. High myopia is more prevalent among females (6.00 D or more, 15% vs. 8.4%).
- e. Males are more likely to develop late onset myopia (onset older than 18 years, 23.8% vs. 14.6%).

If you are interested, I can give you the references that Dr. Septon used. Yes, I know, the prevalence sounds very high. But that is what I have.

Hope this is of some interest.

Herb Black

Subject: Re: Driving without glasses

Nick Halloway (snowe@rain.org) wrote:
: What do you think about people who have badly impaired visual acuity
: without their glasses, say 20/200, driving without them?

: Have you heard of an accident where someone was at fault who
: was driving with really poor vision?

You mean someone like me? I am 20/200 or worse in my right eye, and about 20/60ish in my left eye uncorrected; my glasses correct to about 20/15 overall. My Ohio driver's license is not valid if I am not wearing my glasses, and quite frankly, the thought of driving or bicycling without my glasses scares the \$#!+ out of me. It's doggone stupid, if you ask me. Heck, I don't even ride roller-coasters without my glasses, and there I'm not expected to react to unexpected life-and-death situations!

}What do you think about people who have badly impaired visual acuity
}without their glasses, say 20/200, driving without them?

My glasses provide around -3.5 diopter correction in my worse eye. I don't know how bad this is, but I don't think it's as bad as 20/200. I would not recommend anyone with vision as poor as mine driving without glasses. When I've done it, I've had no trouble on the highway (CARS are big enough to see easily), but my ability to see threats on side streets (not to mention to read street signs) is greatly reduced. This could obviously contribute to an accident, though I've never heard of one caused by this.

Fun fact: In PA, you need 20/80 vision, in at least one eye, to get a license. Yes, that means that if you're blind in one eye and the best correction you can get in the other eye lets you distinguish things at 20 feet that most people can at 80 feet, you can get a license! Daytime only, though.

alt.law-enforcement, rec.autos.driving

Subject: Re: Driving without glasses

I think they would have plenty of difficulty just seeing well enough to WALK to the car, much less operate it.

Many years ago, there was a public service ad on television where a woman was stopped by an officer on a routine traffic stop. The officer asked if she was supposed to wear glasses and she said yes, but she was just on a short errand and "really didn't need them". He asked if she could read the sign ahead, and when she couldn't she fished out her glasses from her

purse. What she saw was a warning sign for a dangerous road condition, on par with a "dead man's curve", or something to that effect, which she would not have been able to negotiate without seeing clearly.

: Have you heard of an accident where someone was at fault who
: was driving with really poor vision?

: Thanks ...

depends whether the other occupants of the car are sober or not. I'd rather drive w/o my glasses (though my eyesite at 20/80 is significantly better than 20/200) which I NEVER do, than let a drunk friend drive me somewhere. If I'm sober, I still have my quick reaction time, and my overly careful driving habits, even if I can't see as well. I can't say the same for a drunk driver. However, if I had 20/200, I'd probably call a cab rather than drive.

Matthew T. Russotto (russotto@wanda.phl.pond.com) wrote:

: Fun fact: In PA, you need 20/80 vision, in at least one eye, to get a
: license. Yes, that means that if you're blind in one eye and the
: best correction you can get in the other eye lets you distinguish
: things at 20 feet that most people can at 80 feet, you can get a
: license! Daytime only, though.

In Missouri, your overall vision must be 20/40 or better to get licensed. 20/80 (which is what I've got uncorrected) is bad enough that I'd be uncomfortable knowing there were people driving with that eyesite (or

lack thereof). My glasses correct my vision to about 20/20 and my contacts to about 20/25 or 20/30. But when I've slid my glasses down on my nose to see what it was like...I couldn't read signs at all (By the time I was close enough to read it, I didn't have time to read them, and I'm a fast reader), I couldn't read license numbers, etc. In short, I doubt my or anyone else's ability to drive safely with eyesite that poor. Unless of course for some odd reason, you are the designated driver, and your glasses got lost or broken. I'd rather have someone with 20/80 eyesite driving than someone who is drunk.

Are there any people from the mailing list in the UK?

If so I will damned well make sure that I stay away from them, not only is driving without glasses stupid, but it is dangerous. If driving without glasses does help these people (and I doubt that it will do) make sure that they do it well away from the rest of us, because not only are they risking their lives, but they are putting the lives of other road users at risk as well.

I think they're idiots. My husband's vision is roughly 20/200. He can't

recognize me at 10 feet, although he can tell that I am a human. He can't *SEE* street signs at the usual distance. He can recognize that there's a car in front of him, but not how far away it is. He has to put on his glasses to make sure his shoes match.

Without his glasses, it would be *slightly* less safe for him to drive if he drank a fifth of gin and then put a paper bag over his head.

This case received a fair amount of publicity at the time, and resulted in one state (Ohio, I think) changing its policy on renewing drivers' licenses by mail -- they now have a limit on how many times you can do it.

An elderly man (in his 80's) had extremely poor vision. Had he been tested, his license would have been pulled. He lived in Florida, however, and had been renewing his license by mail from his home state for a long time, like 15-20 years. One day, he was driving his car down a residential street. He hit a couple of trash cans by the side of the road, because he didn't see them in time.

The "trash cans" were actually two children, both of whom were killed.

The people who are deliberately driving with uncorrected bad vision are endangering not only *their* lives, but the lives of countless drivers, pedestrians, and cyclists. I can only hope that they hit something inanimate before they hit a human or animal. I have neither sympathy nor respect for them. If I knew someone who was doing it, I would turn them in.

Hmmm. I was into that once. The idea is to go without glasses as much as possible. But when somebody like that is operating a vehicle that could easily kill or maim somebody and the traffic signs, legal speed etc. is based on drivers with 20/20 vision I think that person should be stopped.

Heck, I had enough problems being a pedestrian as nearsighted as I am. I especially had problems seeing gray cars. It never even occurred to me to drive or even ride a bike for that matter.

the occult

- *Subject:* the occult
 - *From:* Bills@vav-nun.com (Fr. ALSO)
 - *Date:* Sun, 28 Jul 1996 22:00:01 -0700 (PDT)
-

Springboarding from my earlier twisted metaphysical offering, (which was rather off the point im afraid), I'd like to speak squarely on topic and hopefully add some new viewpoints:

This is to add to the proposal by Elena that psychological exploration can uncover keys to the solution of myopia (and other manifestatons of anxiety).

As the subject line suggests, the topic is the occult. I'd like to suggest the value of its doctrines in vision therapy. For the benefit of those of you who have only heard the Billy Graham definition of 'the occult', this post should provide some valuable balance. (a preemptory statement to avoid lengthy irrelevancies similar to the driving issue)

The etymology of the word occult means: 'hidden from view'. This suggests immediate potential for the student of improving vision, and in fact it does contain much of value. The subject is considered illogical and irrelevant to many, this is partly due to the illogical and irrelevant statements of some of its adherents, but more because of the campaign of bloody persecution waged by the Catholic Church over ten centuries to maintain their monopoly on spiritual empowerment resulting in a break in the roots of this science. I will define occult more closely as 'Hermetic Science', that school of thought headed by the legendary Hermes Trismegistus with roots purportedly several thousand years BC.

Modern Science itself suffers from a prejudice brought about by this suppression policy, as 'the age of reason' was kindled--disavowing the existance of anything not measureable in response to such eggregious practices of the Church as jailing Copernicus for life until he recanted his statement that the Earth revolved around the Sun! Currently, the vanguard of modern science is discovering many interesting things in the field of quantum mechanics which sound awefully mystical. My personal hunch

is that our cosmological paradigms will come "full circle"(a basic Hermetic principle) to eventually restate all of the ancient theorems in modern form.

What does this have to do with emotion-work? The thing that is "hidden from view" is our subconscious. Like the iceberg, a much vaster chunk of mind is not "in the Sun". The Hermetic method uses a set of symbols and analogy to negotiate this hidden portion. the purpose being to understand and manipulate it. The symbol of the Sun, for instance, corresponds to the Consciousness, the Rational. We see sharper in full sun, but it also hides much from our awareness including the vast sea of Stars still overhead. Our Sun worshipping society echoes the scientific/rational bias.

The Day/Night image is a useful analogy for our discussion here as the Unconscious equates to that vast sea of Stars, giving one an accurate view of the proportion of the conscious mind vs. the unconscious (a much better analogy than the iceberg it occurs to me). The incredible vastness of the unconscious this analogy suggests is difficult to accept due to the notion of separation inherent in the current scientific/rational cosmology. How could one person contain such an awesome portion within their little brain? But the mystical doctrine of all persons being an inextricable part of the Universe and NOT separate and dispensable chunks thereof makes the analogy hold up. And it goes beyond analogy, this Oneness can be directly experienced and is the inspiration behind the many religious texts extant. >From this point of view, the metaphorical works begin to appear much more rational, using the devices of poetry, metaphor and analogy to describe this reality.

This Body/Universe dichotomy inherent in the modern scientific paradigm is a source of much anxiety. The fear of death, accidents, loneliness, are all traceable to this supposition. My suggestion here is that the language of the occult, the symbolism connecting the outer to the inner was carefully crafted for several thousand years specifically to facilitate the rational mind's search of this hidden realm and give it tools to discover the sources of pain and joy and to help one to enjoy health and happiness.

Students of Jung are familiar with his work with occult symbolism, classifying Gods, Goddesses, Demons and other Spirits as Archetypes. His description of the Collective Unconscious creates quite a raise of the eyebrow still. His therapy depends largely on analyzing dream symbolism, that place where the subconscious mind is seen. (often at night!) I mentioned the astral world earlier, and the command of this realm is the goal of every occult student- it is the conscious entry into the subconscious realms, a sort of willed dream, and is populated by the complete gamut of 'archetypes'.

I will cut this brief intro here. My point has been to offer the suggestion

to those unfamiliar with this body of work that much fruit may be had in this study. The increased attention to the world it inspires adds much to one's health. Unfortunately, the source of my visceral charge earlier to 'trust noone' is largely a result of this study of mine over many years. The thread of meaning in the Hermetic Sciences has been fairly well trampled after being forced underground for a thousand years, and nowadays the occult is a source of great mileage for the iconoclastic showman to put out magical writings which add nothing but confusion to the subject, some are even malignantly deluded. How does one know? a classic 'blind leading the blind' conundrum which can only be gotten past by patience and trusting one's OWN mind, which can work just as perfectly as any EYE can, given the right conditions!

with Love,

Hello fellow Vision Enthusiats.

I am very curious about the results that people are experiencing using Vision Freedom (sold by Brian Severson). I asked the same question a few weeks ago but my name had been mistakenly removed from the list so I never got an answer.....Any replies are welcome.

Cheers.

Howdy.

This morning I noticed something *\*VERY\** weird. After I woke up I went and sat down on the couch on my living room and I *\*WAS\** able to read the clock from my VCR (something I usually cant do)...After going through all the morning tribulations: shave (almost cut throat), shower, get dressed et al I noticed that after sitting on the couch the clock seemed a lot more blurry. So? I am wondering , is the improvement acuity related to the facyt the my pupil (probably) is dilated? Any ideas?

Cheers.

Yes it is; on that "e." point, what is the latest recorded age  
for myopia to develop. Also is this really "late onset" that  
is being recorded or just "late diagnosis"?

Thanks,

Mike.Ellwood@rl.ac.uk

Sleep allows one to act out the various events of the (usually) previous day either celebrating victories or tragically expressing unfulfillments. this refreshes and relaxes the psyche and the eyes naturally follow. As the morning progresses, the daily routine of shaving and showering signals another day which inevitably reminds one of the various lingering features which have established stress and so the myopic condition, and it reasserts itself.

Normal dilation takes only a second to adjust.

Anybody with some dream therapy info?

Mike;

Myopia onset actually increases after age 40 again, but this is due to mostly cataracts. The changes in the lens in cataracts causes it to become more powerful, more plus, ie, more myopic.

Also, some stats:

At entrance to school, 2% of children are myopic

Age 6 through teens, prevalence of .50 D or more myopia increases from 2% at 6 years to 20% at age 20.

Prevalence increases from 20% to 30% age 20 through 40.

For those of you who sometimes wonder about myopia and education, some more stats:

Undergraduate college students: males-35%; females-40.6%.

Graduate students (Harvard Business School): 43.5% myopia.

Optometry students (Pacific Univ.) 1994 study- 71.5% myopes!

So it is pretty obvious that either more school causes more myopia or myopes like school more than non-myopes.

I regards to late onset vs late diagnosis, I think it is probably really late onset in these stats rather than late diagnosis because, at least I know in the US studies, almost all school kids are screened for myopia which is a very simple chart test and so easy to detect. In contrast, hyperopia is often overlooked because schools don't screen for it as well and so studies of hyperopia are probably flawed due to late diagnosis.

Enjoy!

Herb Black

As many of you know aspartame marketed as NutraSweet, Equal, Spoonful, etc. was approved for everything in the grocery store without advising the public. Obviously, because of previous hearings in Washingtons and an outcry from the public for years the FDA wanted no interference. Dr. H. J. Roberts notified me he had a copy of the Federal Register and we had to the 29th to fax objections. The fax number is 301 594 -3215 and you must put Docket number 94-F-0405. This is Dockets Management Branch, HFA-305.

Aspartame destroys the optic nerve because of the methanol (wood alcohol) which converts to formaldehyde even in the retina of the eye, and it destroys the central nervous system. As case histories continue to flow in the FDA has approved it for everything in the marketplace.

We are trying to get this reversed but a million faxes would help. Please spread the word. Most of the public doesn't know and people are continually going blind. One case was just faxed from Stephen Krol this A.M., diabetic, who said he had completely lost his vision in one eye. Then someone gave him one of our warning flyers, he got off of it and his vision came back. He was one of the fortunate ones! But if its in everything people will not be able to avoid it.

You can get more info from our auto-responder by emailing me for a directory. Simply sendme help in the subject line like this.  
Subject: sendme help

You can email me personally for a copy of our warning flyer. Please

spread the word to all networks. Midnight is the deadline.

Yes it is; on that "e." point, what is the latest recorded age  
for myopia to develop. Also is this really "late onset" that  
is being recorded or just "late diagnosis"?

Thanks,

Mike.Ellwood@rl.ac.uk

Funny you should bring this up as I am exposing myself to some of the healing concepts in tribal religions, paganism, or whatever you want to call it. It tends to sound a lot like "New Age". I recently took a short course in parapsychology. The instructor, Diane Morrissey, had been electrocuted at home, had an out of body experience but woke in the ER. She said she was severely myopic, but when out of body, her vision was perfect. It's like the energy body remembers something that the physical body forgot. So how do I get my eyes well using this line of thought? If I come up with anything good, I'll let you know. I think we could all pray for each others eyes.  
Julie

This is an interesting statement. This suggests that a language formation holds an emotional charge. Thus 'definition' could possibly be the mechanism able to corral an emotion. All of my best psychic successes have had this feature; a definition was challenged and in challenging and going against its advice, i gained an opening of new power. The implication is that to break down artificial barriers-restrictions- is a key. This seems totally obvious, i just never thought about it so simply! Of course some of those restrictions seem SO necessary sometimes, it's easier said than done. But SO satisfying when done!

# Need help for lazy eye

---

- *Subject:* Need help for lazy eye
  - *From:* Mark Herold <[HEROLD@brk.bfg.com](mailto:HEROLD@brk.bfg.com)>
  - *Date:* Tue, 30 Jul 1996 09:13:59 -0400
- 

Hi,

This in the final update in Melissa's Amblyopic condition, part of the following text is copied and pasted from historic postings I have placed:

About year ago I started my own personal Internet search for data relating to amblyopia (Lazy Eye). This search was driven by the need to see all possible options being explored in the treatment of my daughter's (Melissa) amblyopia condition. In the following text you will find a brief description of the history and option that I have found in regards to her intractable amblyopia. For the record I am not a medical doctor, I 'm just a father seeking out all options for the treatment my daughter... I would like to share what I have found so far.

## Basic Background:

Melissa was about age 5 when she was diagnosed with amblyopia, at that time her right eye had the visual acuity equal to about 20/400 sight... this was after here vision was optically corrected with glasses. As a result of this patching was prescribed and steady improvement was made over a period of time (about 6 months) but eventually her improvement plateaued at about 20/100 visual acuity. This acuity level, in her right eye, has remained for over 6 months now, and she is now slightly over 6.5 years old.

## Information Located:

After posting a number of information requests, and receiving a plethora of information, I finally was pointed to research that was being conducted at the Ohio State University in

Ohio-USA( for detailed information see the proceedings of the 13th Eye Research Seminar conducted by Research to Prevent Blindness - article Treating Older Children With Intractable "Lazy Eye", p37-39, author: Leguire L.E. ). Basically real improvement appears to be possible for children that have stopped improving under standard patching therapy for Amblyopia, this includes older children - such as ones in their teen years. The method involves using patching in conjunction with a very low dosage of Levodopa/Carbidopa over a 7 week period.

Present Condition:

Melissa recently completed the treatment plan detailed above and no noticeable side effects were noted during the treatment period.

Final Results:

I took Melissa in for final check up last Thursday, at that point she had been patched full time (about 11.5 hour/day for about 7weeks) along with using the medication noted above. The results, unfortunately, were quite disappointing. She is still testing at 20/100 visual acuity in her amblyopic eye. Her other eye is testing at 20/20. Even though the result, in this case, was basically no improvement .... I still consider this as an option that should be at least examined for other children with Amblyopia.

Alex and fellow readers of this list, if you happen to run across any new treatment options I would clearly like to hear about them as soon as possible.

I hope this data can help some one else in the future.

Mark Herold

Or, the 'energy' body displays something the conscious mind forgot--that we  
are perfect.

>So how do I

try becoming aware of your astral body. Astral Projection by Denning and  
Phillips is considered a good standard instruction manual.

>I think we could all pray for each others eyes.

This is no joke! though i prefer the term 'meditation'

I have to apologize for using some terms loosely, without specifying what it is exactly that I mean -- I know part of misunderstanding in any disagreement stems from all kinds of vague, qui-pro-quo terminology. When I was talking, in my statistical estimate and elsewhere, about "emotions," I should have used another word -- feelings. I will try to be a bit more specific in the future and say,

1) "rational/intellectual/thinking/symbolizing processes" when I mean psychological processing of experiences, the upper-level, neocortical consciousness. I will say 2)"emotions" or "affective processing" when talking about our discerning stimuli as positive/negative, pleasant/unpleasant, something to seek/avoid, etc., or mid-level, limbic consciousness, regulated by the middle brain. And I will say 3)"somatosensory" when talking about visceral/kinesthetic, etc., consciousness, the kind of processing associated with the inner brain. Finally, I will say "feelings" or, alternatively, "(w)holistic consciousness" to denote experiences that are processed everywhere at once, by the whole brain and whole body and all organs simultaneously. In case it's a surprise to anyone, or in case someone thought it was a metaphysical concept, that's simply the way life on earth functions: it feels. Its animal part to which we can still somehow relate (at least if a scientist who has "performed a controlled experiment" tells us we should), used to

have feelings some 300 million years before it invented a neocortex, because it already had (and still has) a body complete with a lot of organs, and a middle brain and an inner brain, no better and no worse than ours, to process its interactions with its environment. Consciousness evolved as a systemic phenomenon, as an ability to "notice," respond to, and integrate, experiences, not "some" experiences but all experiences. That would be any species' undoing if it managed to have experiences and ignore them -- for instance, drink sand from where water used to be and be "unaware" of this particular fact. It could be unaware on a higher level (for instance, ignore the unpleasant taste) but not on a lower level (the cells needing water would "notice" that they got something else instead, plus they would "notice" that they still need what they needed before, only more so). One needs to be UNFEELING in order to be unconscious. No creature on earth is without consciousness, or it wouldn't have survived. Consciousness is any live creature's ability to notice its all experiences with everything it has to notice them with. Johnny-come-lately, homo sapiens, is grossly mistaken when he thinks that he has learned how to feel by learning how to think. He's mistaken when he thinks that he's learned how to exist by learning how to think. His "cogito ergo sum" means "I have a neocortex therefore I exist"-- which is not so much idiotic as ahistoric. Existing is something we've been perfecting for so much longer, it would have been funny he's come up with this particular idea if it wasn't so tragic.

So "emotional trauma" was a bad term for what I meant. A good term will be "a trauma to one's feelings," which means, a trauma to your

- 1) first-level consciousness (if you're old enough to have a functional neocortex), of the type, "I think that's not fair!" or "now I understand -- when he/she was talking about love he/she was lying to me," or "I did something bad in seventh grade/in a past life, and therefore deserve to be punished";
- 2) to your second-level consciousness -- physical pain of being hurt in an accident, or beaten or shot or roasted alive as a sacrificial offering to gods, etc.;
- 3) to your third-level consciousness -- the trauma of having to adapt, beyond capacity, to adulterated inner/outer conditions -- for instance, to drinking sand when you need water... or to the need to triple your adrenaline production in response to some events occurring in your first- and second-level consciousness, plus to produce extra hydrochloric acid in your stomach to digest what's having trouble being digested because you're under the "not enough oxygen" conditions of stress, and the blood is diverted elsewhere from the walls of your gastric tract and from that sandwich your well-meaning stomach was CONSCIOUS OF and planned to process in peace, and still has to process somehow, whether in peace or not. Any kind of trauma occurs not only on its own level but is carried over to all levels of your consciousness, to your whole being, to each organ "in its own language." (That's an important point of disagreement between our views, my mystic-minded fellow i\_see'ers: we don't store metaphors in our muscles.

We store metaphors in our neocortex. Muscles store information about the SAME experience in a DIFFERENT language. It's not symbolic -- it's direct. The language will be the speed of nerve endings growth or their conductivity, core body temperature changes, etc. That's body language, not what I saw recently when a self-proclaimed adherent of "holistic" approaches showed me how she "talks to her body." She actually spoke to it in plain, simple English, like to a dumb child. It's not dumb -- it speaks metabolic, biochemical, electroconductive, thermoregulatory, photosensory, and many other ancient languages that haven't become extinct in hundreds of millions of years, unlike so many human languages in a much shorter time!) This is what I mean by trauma to your mind/body/spirit, for purposes of further discussion called "a trauma to feelings."

As for mind over/under/behind/before, etc., matter -- I don't disagree with anything and I've even made it through The Dancing Wu Li Masters, a history of modern physics that views physics as a science that really studies the structure of consciousness. But I don't have (and don't care to fake) the same first-hand understanding of the trans-atomic, pre-Big-Bang, after-life, whatever, "ultimate realm" that I have of "the feeling, conscious life," and I have good reasons not to care, for now. I think we aren't ready for that lesson yet, whatever it may be. We're like a first-grader who's failing arithmetics while daydreaming about his future Nobel prize in math. Maybe he'll get it after all -- but hardly as an automatic reward for flunking arithmetics.

I did come to revere something finally. It's life on earth. That we are part of it and are designed on its general principles -- which means, NEVER unconscious, never unfeeling, but, rather, a species facilitated with a handy but also potentially life-extinguishing ability to ignore (or fake, i.e. symbolize) and ultimately "not know" what we're really feeling, is of a much greater concern to me than who was here first, mind or matter. It's like asking what's ice cream, ice or cream. It's neither. It doesn't have to be either/or, or to consist of one plus the other, in order to exist. It's not a dichotomy, and consciousness and matter are separated only in a split mind/disjointed body/broken spirit. I used to think human spirit is split in two. That was wishful thinking. It's split in multiples of six. Three levels of consciousness split twice horizontally and once vertically by STOPPING/PREVENTING integration of feeling of every single experience produce the kind of "consciousness" we're so proud of. That's what it takes to be human these days.

Have fun.

Elena

Astral Projection? I used to make fun of it, actually, I still do, only due to some "weird " experiences in the last few years, I think it's for real. I'm in an on-line study group now going through "The Women's Book of Healing" by Diane Stein which deals with auras, the laying on of hands, crystals and gemstones, chakras and colors. I just picked up Dolores Kreiger's (RN & PhD) "Therapeutic Touch"(is it possible to underline anything on a computer? Mine will erase any word I try to underline.). I am interested in all these concepts, I may even astral project all the time without remembering it. I have these vague impressions of having been on the moon.....They're a little different than my occasional dream recollections. Just enough to make you go hum.....!?. With all these books to read, how am I ever going to get rid of this myopia? I think I got it by reading too much in the first place. I need to meditate more. Please meditate on my behalf, I'm visiting a sceptical ophthalmologist on Monday. If my vision is even slightly improved, I will be very excited. If it's not, I'm not doing a very good job with VT.  
julie

Prior to consciousness, which for homo-sapien includes thinking, there is only more speculation. In the \*describing\* of the source of life and mind, \*any\* model becomes self-defeating. However, i agree with your summation with the caveat that thinking is nonetheless a valid \*and necessary\* activity.

I'm flashing on an analogy to the treatment for alchoholism; "AA" , the treatment essentially rests upon the absolute ban on the consumption of alchohol. Though effective, there is an artifice implicit which doesnt actually solve the problem, only the symptoms.

>SAME experience in a DIFFERENT language. It's not symbolic -- it's direct.

Then i guess we are in agreement but are you suggesting superiority of one language form here? Of course the metaphor is an expression of the language function, and the spasm is the expression of the muscle, are they not both fractional responses to the same experience? I agree strongly with your suggestons of a wholistic process, where a bee sting or a hateful look is felt throughout the system. This is the ideal goal, i believe, to FEEL everything as fully as possible. To 'acknowledge reality' is a way of expressing this. The seventh emanation of the tree of life (cf. the biblical creation of the world) is another way of describing it, (for the mystic-minded;) .

In the case of a chronic muscle spasm which denies us the ability to visually accomodate, the theory you suggest, if i got it right, is that traumas (painful events (whether physical or ideological)) exist in ones past which have yet to be fully \*fealt\* and so are still 'unfulfilled' and must be released for the spasm to vanish. My suggestion in response to Linda's reply, that a thought holds the key, i can see could be misleading if taken as the 'cause', but i meant to suggest that the thought is symbolic of the trauma and could be more readily identifiable and modifyable. Or perhaps it is simply a part that must be dealt with as well. But theory aside, i know that it works to remember incidents and question the conclusions i have held.

>

>I did come to revere something finally. It's life on earth. That we are >part of it and are designed on its general principles -- which means, NEVER >unconscious, never unfeeling, but, rather, a species facilitated with a >handy but also potentially life-extinguishing ability to ignore (or fake, >i.e. symbolize) and ultimately "not know" what we're really feeling, is of a >much greater concern to me than who was here first, mind or matter.

Analysis is basically boring unless it gets applied. That is certainly my intent as i'm sure it's yours. Let's talk about techniques for putting the theory to work. Let's reclaim our vision!

>I used to think human spirit is >split in two. That was wishful thinking. It's split in multiples of six.

hmmm, and six gets you;

>Three levels of consciousness split twice horizontally and once vertically >by STOPPING/PREVENTING integration of feeling of every single experience >produce the kind of "consciousness" we're so proud of. That's what it takes >to be human these days.

that path of the Scorpion is so scary though! Translation; the full integration/engagement of the world is a total committment--it is Love--

and it is a Death to the Ego. Fear of Change prevents that final actualizing. It's an extremely basic response, i dont think modern society is really the problem (actually a symptom), the tendency is an result of the development of the frontal lobe, imagining our(perfect)selves, and resisting unauthorized modifications to that picture.

>  
>Have fun.

that's practical advice!

> detachments. It's much more than a visual acuity problem.

> From what I've read, myopia come in many different flavors. What works  
for one person may not work for another. People seem to draw a  
distinction between severe myopia and mild myopia; severe myopia is  
generally considered to be genetic and mild myopia may be  
environmental. Severe myopia seems to occur at about the same  
frequency regardless of amount of near-point work; but the same  
didn't seem to be true of mild myopia. Severe myopia is likely  
to be associated with the  
risks that you mention, retinal detachment etc. Do you know if  
mild myopia is associated with these risks? There is also myopia  
that's associated with various genetic syndromes and with diseases --  
I seem to remember it being associated with diabetes.

> This surgery is based on the concept that myopia is a normal biological

> variant. But that doesn't mesh with up-to-date information. There is more  
> than one cause for myopia. Ask your doctor how he or she knew that you  
> didn't have pseudo-myopia, which is considered to be a reversible condition.

I have wondered about that, whether surgeons screen for "pseudo-myopia".  
Some optometrists say they screen for myopia associated with  
accommodative spasm, by giving a drug to totally relax the ciliary  
muscle. If totally relaxed refraction is still myopic, I suppose  
they conclude nothing can be done with vision training.

I'm not sure though whether this screen is effective in screening out  
all people who could improve their objective refraction without  
surgery.

Also, people who've acquired myopia who have the surgery but no  
education about reducing bad visual habits, near-point stress, etc.  
might be at risk for developing myopia again after a few years.

It's not clear to me how the surgery "is based on the concept that  
myopia is a normal biological variant". It is possible that people  
can acquire myopia which is not reversible -- there are various  
theories about how near-point stress might cause longer eyeballs, etc.  
so that the pseudo-myopia becomes permanent myopia.  
If it is not reversible, surgery might be the best option.  
Myopia is only reversible in some cases.

If someone is somewhat myopic but not very myopic, it would make  
sense to at least look into non-surgical treatments. Perhaps, one  
reason that people go for the surgery is that vision therapy is  
a lot of work, slow, can be very expensive and doesn't work for  
everyone. The surgery costs a couple thousand dollars or so,  
and people don't have to put a lot of time into it, and works  
pretty well most of the time. It's easy to imagine weekly  
vision therapy appointments adding up to \$\$\$.

Re: mild vs severe myopia and risk for glaucoma etc. From my recollection of various conversations and reading, there is not a clear demarkation between mild and severe myopia and the risk or non-risk for other eye problems. I don't remember anything on all environmental factors being controlled, yet still myopia progressing in a significant portion of the population. I think a study like this has yet to be done. But my information is limited. I do think picture is clearer for the more severe cases of myopia. But I still haven't seen or heard anything that clearly states that mild myopes have the same risk for glaucoma etc as the general population.

Another MD friend who I would call a moderate myope- I don't know her exact numbers I think she's around -3 to - 5.- asked her ophthalmologist at her last visit about my concerns. She's on the faculty of my medical school, and in family medicine too, just in case you care. Her doctor told her she was getting some degenerative changes already. I may see her next week and get more details.

I have asked this of several ophthalmologist but have not been told that mild myopes have no increased risk for problems. I have asked for specific numbers on risk ratios and the response I've gotten is that severe myopes have a definite increased risk. Maybe mild myopes have no increased risk but no one I've talked to, and nothing I recall reading has been definite about this.

My own doctors have always treated this as a normal variant. My friends have had similar experiences. I've never had an MD mention VT as an option.

Once I found out about VT, I did visit an optometrist for evaluation, but I really don't need to keep going any more than someone who wants to loose weight needs to see an M.D. to be in a diet and exercise program. These professionals have nothing more to give me. I just need to do the work myself.

And if VT is so hard, how do we know that a person's myopia is irreversable vs they are having a problem with compliance, or that the speed

of reversal is logarithmic, the further out you go, the harder it is to get back? And what about future research regarding medical (non-surgical but not natural) treatment possibilities for myopia? The money in research has gone for this laser surgery. Probably because there is a business interest in selling the laser equipment. But in the long run, will surgery have been the best medicine? Two years ago I thought the surgery would be a cure for my myopia. I am in the medical profession, I did read a bit about it and was asking a lot of specialists about it. I hated my glasses and was ready to go with the surgery. Now I would say I had a very limited understanding of the problem. And not a single MD informed me of my options. Does the average person undergoing this procedure get informed consent? I don't think so.

Julie;

It's too bad that MD's so often dismiss other healing modalities they haven't learned about in school, assuming that they have a monopoly on healthcare and health knowledge. I think people are getting very tired of that. The truth is that VT is a very complex field to know about and most OD's don't even know much about it since it is not being taught in optometry schools as much as it used to be because optometry is all excited about being more "medical". A mistake I think. Anyway, I do not think you can just do VT on your own anymore than most people with a weight problem can lose weight PERMANENTLY without some sort of support, either professional or like OA.

There are OD's that specialize in VT and you will find FCOVD after their name. It is well worth seeing one of these professionals with extensive postgraduate training and certification in VT.

To Julie and all the skeptics:

I am silently following these threads with great interest. My two pennies worth is for those who are interested to read a book called The Infinite Mind by Valerie Hunt. This skeptical researcher presents very compelling scientific evidence that has converted me into looking into the idea of energy and fields of energy more deeply and its relationship to emotional and non-visible forces at work in healing eyes and vision.

Enjoy while palming,

> julie  
>  
>

I agree that the research and money has gone into the laser surgery and the like. And that is in great part why I have confidence in the surgery. This is not a new procedure and it has been around since the 1950's where it originated in Russia. I understand that Russia continues to correct through surgery instead of eyeglasses, if there were long term effects we would have heard of them by now. Also we must recall that the FDA has approved the eye surgery with simple RK and also the PRK (laser). Whether we can trust the FDA's studies or not is another debate, but we do know that the FDA does take longer to aprove new

procedures so that their case studies can be as thorough as possible.

Now regarding all the extra "information" about various possible side effects or risks, I wonder if that will not just confuse the issue? I decided to make an educated decision and on all the literature I picked up. I based my decision on "solid" research and studies and tried to filter out most of the hear-say and unproven theories. It does seem that we have some proof that VT works for some, but we also have proof that surgery has worked for many more. Then its up to the individual to make an educated decision which solution is best for them. Then drop without a second thought all the scare and superstitious comments that often seem to surface around all sorts of healing procedures. Is there any "healing" alternative that does not have any risks or side-effects?

Mario

I will share the statistical results with everybody and GUARANTEE ANONYMITY to all respondents. I expect either some eye-opening correlations everyone will be able to see, or a refutation of my present theory (partial or total). I am open to either outcome (I went through the process of defying my own next-to-last hypothesis a number of times and I don't mind being proved wrong -- a negative result is a result none the less.) I'll share the theory in its entirety, and in case it's as significant as I now think it is, the repercussions for our present "let's reclaim our vision" quest will be direct.

Here goes:

I. Please respond in figures to questions in this section.

1. At what age was your vision problem first diagnosed?
2. How strong was your first prescription? What was your unaided acuity?
3. How high was your refraction error at its highest? At what age?
4. How bad is it now? How old are you?
5. For how many hours a day did you wear your glasses/contacts at various ages?
6. Did you wear full-strength glasses for near-point work (reading, etc.)?
7. Average daily amount of near-point work at different ages?

II. Please ask your mother for details if you don't know the answer to any of the questions in this section.

1. Were you born at full term or premature? If premature, specify age in addition to weight.
2. Complications at birth (if any): a) normal natural birth; b) Caesarean; c) cord strangulation; d) suffocation on fluids; e) a twin; f) other. Please include details (wasn't breathing/had to be revived, bluish or purple skin color, loud/weak crying, etc.)
3. Was your mother medicated with tranquilizers or painkillers at any time while in labor?
4. The duration of labor?
5. Ask your mother if she remembers any details of the environment of the

delivery room: cold/hot, noisy and hectic/quiet, etc.. Give details if you can.  
6. The lighting of the delivery room: bright/dim, incandescent/fluorescent, few/many reflections from bright-lit objects, etc.  
7. Were you separated from your mother immediately after birth? If yes, for how long?

III. Be specific or poetic in this section, whichever seems appropriate.

1. Please describe the circumstances around the time when you first started noticing difficulties with your vision.
2. Can you recall any specific experiences that made you aware of a change in vision for the first time?

I look forward to your answers!

Elena

I have to disagree loudly. I see this as elitism - the same kind of professional snobbery that is rampant in the "accepted" medical establishment. "You people must get our superior, professional opinion before attempting an exercise or weight-loss program." The truth is, doctors receive little or no training in nutrition. The information they do have is based on the male model (where all the research money goes) or comes from drug companies who want to sell their chemicals.

Anyone with an interest is capable of learning what is involved with vision therapy. It is not necessary to earn a degree or take classes to learn. Just as a degree and medical license is no assurance of competency, the lack of these things does not indicate incompetency!

I have not found my program to be expensive or time consuming. It fits neatly into my lifestyle, and I am pleased by the results I have gotten so far. I do use eyecare "professionals", because I am unable, legally,

to prescribe my own lenses. I choose the strength of those lenses, but am not allowed to purchase them without a "note from the doctor". So far, the costs are about the same as I was spending just to maintain my myopia - that seems like a real bargain to me.

I hope no one has been discouraged from exploring their options, just because they are not "qualified optical experts". After all, it was a qualified ophthalmologist that got me started on this addiction to minus lenses!

Mary (getting down from her soapbox) Marlowe

Mary;

I did not say that people should go to an MD for weight loss- that's the LAST place I would go. I too am not fond of MD's, especially ophthalmologists, since it was one of those who missed my binocular vision problems as a child. I was seeing double and he told my mother I was faking so I could miss school! So being a good, submissive child, I assumed that the "adults" and the doctor were right and I was wrong, so I stopped seeing double, by suppressing one eye (alternate eyes), subconsciously of course! Which of course left me with no depth perception, clumsy, bad at sports, any activity or thinking process which required 3D visualization, etc. Finally, my daughter had similar problems and the occupational therapist helped her a lot but then recommended VT which I had never heard of. But being good yuppy parents, we sent our daughter and it made a HUGE difference in her. So I then went through VT myself and the OD liked me so offered me a job as a VT therapist which I did part-time while working at my regular job (geology).

I saw so many kids come in either in special ed or about to go into it, beyond help many times, discouraged, negative, etc. After a few months on VT, they were positive, on the honor roll, mellow, etc, etc. The family was also very happy to say the least.

This is the type of VT I am talking about, not so much myopia

reduction which seems to be the item of greatest interest to this list. I frankly think myopia reduction is the least important aspect of VT especially for kids who are failing at school, many of whom have NO REFRACTIVE ERROR! Not myopic, in other words. Or if they are, VT helps them anyway.

So that is my story and why I am now a 3rd year optometry student going through a ridiculously stressful program so that I can maybe help a few kids not go through what I did. If that is elitist and "medical", then so be it. The stuff we do cannot be done by people alone usually because it requires equipment and training to know what to do. We do ask them to do exercises at home as well as come in periodically for offive visits.

Myopia reduction

I know CAN be done at home with a book about Bates or one of Jacob Lieberman's books. That is just not my interest area.

My 2 cents worth.

Herb Black

Mary Marlowe expressed my immediate reaction quite well. So instead i'll just ask, why do you believe this? Is it because of special difficulties a non-professional is unable to discover on their own, or because of the extra encouragement and 'prodding' a personal trainer can provide, or what?

I have known of VT for 17 years and i still wear glasses. I have achieved successes of near independence a couple of times and i have reduced my prescription over all, but i havent gotten that PERMANENT state of 20/20. My understanding of this is that i have not worked diligently enough, the pressing forward with my busy life I've given priority and just slapped on the specs instead! I'd like to hear any of your info on how a pro can make it happen.

What are the statistics for a professional therapist's success rate bringing an entrenched myope to PERMANENT 20/20? How about the average for solo efforts?

myopia is expansion glaucoma (per Kelly of Bath, England, 3rd Int. Congress on Myopia, Copenhagen, August 24-27,1980, Documenta Ophthalmologica, Proceeding Series, Volume 18,1981, Eds. Fledelius, P.H., Alsbirk, and Goldschmidt.)

From my understanding, there is research being done looking for a quick fix for the overall problem, fixing the disease at its biologic root, not just from the visual acuity aspect. The only article I have on this is Raviola, M.D., and Wiesel, M.D., The Neural Basis of Myopia, ON THE BRAIN, The Harvard Mahoney Neuroscience Institute Letter, Summer, 1995 (and these guys I am told are really, really smart!)..

Julie,

These articles you mentioned sounded really interesting. I always wondered about the possible link between myopia and glaucoma..and wonder the things we can do for glaucoma possibly is also good for myopia, such as Vitamin C for lessening the pressure in the eye. Could you tell us more about these? I believe I won't be able to find these articles in my local libraries.

What kind of VT do you do?

Thanks.

Dear Herbert,

Please forgive the intense knee-jerk reaction I had to your post. I am glad you made clear that you were talking about a particular case where you felt it unlikely that people could ferret out their own information. I still believe the information can be had without seeking a "specialist", though many people are more comfortable hiring outside help.

I recommend research - whether doing-it-yourself or hiring an outside contractor. For me, blind faith is a thing of the past :)

I have a thought on children and vision: Are schools (and the rest of us, by extension) asking them to use their eyes in developmentally inappropriate ways? I think it much more likely that there is something wrong with our relatively new (150 year old) compulsory education system, than with our children (who usually manage just fine until about second or third grade).

Bill;

I refer you to my earlier post of today to Mary Malone. Perhaps I am guilty of the very professional arrogance that I so deplore in others. What I was trying to say was that I think VT often requires a "personal trainer" as you say or some kind of support just like permanent weight loss or permanent abstinence from alcohol, etc.. There have been studies done here at Pacific (or at least one study I know of) that show the critical importance of motivation of the person by SOMEONE to keep going in VT. I myself went through VT for 2 years and I learned that there came a point when my visual system was breaking down so that it could re-form into a more healthy one. This is called a "transition" by some and can be VERY unpleasant and even scary. It is my opinion that many people drop out of VT (and other types of therapy too) at this stage unless they are aware of this and have much support to grit their teeth and go THROUGH it and not run!

In addition, as I mentioned earlier, when I say VT I am not just referring to myopia reduction, but also to therapy for a myriad of visual system problems, such as accommodation disorders, binocular dysfunction, strabismus, amblyopia, vertical phorias, suppression, tracking and perceptual problems. These I think do require some professional structuring of a VT program which may then be done either entirely or partly at home. Sometimes special equipment and computer programs make the therapy a lot more effective. Having been exposed to VT as a patient, then as a therapist, and now as an optometry student (3rd year and counting!), I can tell you that it does seemingly miraculous things for kids (and adults) with visually-related learning disorders. It affects their whole lives and is very exciting to see the results. The ONLY failures I saw in my opinion, were of motivation. So that is why I stress help in motivation.

Myopia reduction I believe probably CAN be done solo with a good book of Bates or Lieberman material. It is controversial even within the VT community. There is a professor at New England College of Optometry (who's name escapes me) who specializes in this and works at Harvard University doing myopia reduction therapy with the college students. I can tell you it is very low tech but does require some special knowledge, neither mystical nor esoteric, just learned over time! She learned much of her knowledge from Dr. Amiel Francke in Washington, DC, who by the way got rid of my nephew's myopia years ago, as well as the OD at New England's myopia(as an adult).

I will confess that myopia reduction does not hold the fascination or intrigue that other types of VT do for me, but that is a personal preference. As far as stats go on myopia reduction, I have none and I am not sure there are any. But I will look it up next week AFTER my

National Boards for which I am cramming madly.

Thankyou for your interest and I will try to do some research on this topic a little later.

Herb Black

- 

This comes from `_Patient Care_`, September 15, 1995, Sher, Trobe and Weingeist, all M.D.'s re: laser, not the RK

"-Regression of more than 1.00 D (this occurs in 12% of patients with myopia of up to -3.00 D, 28% with -3.10 to -6.00D and 60% with more than -6.00D)  
-Reduction in best corrected visual acuity of more than one Snellen's chart line in 3-4% of patients with myopia of -1.00 to -6.00 D and greater  
reduction in patients with more severe myopia  
- a halo around lights sufficient to impair night driving in 12%." p. 62

So from my present understanding, the worse your myopia is, the more likely this surgery will not result in long term 20/20 vision. Also, the more likely your myopia includes an increased risk for glaucoma, retinal detachment and vitreous degeneration, meaning the surgery is not a cure for your problem. Though I was originally (and I think most patients still are) under the impression that this surgery was an overall cure.

This article also states, "Although myopia can be an extreme inconvenience, it is not a disease." p. 56 This I think is clearly mistaken. I have received a letter from Dr. Trobe acknowledging some of my concerns with the note that he would pass my questions on to others in the field. I haven't received a reply just yet, but I'm sure these good doctors will explain things to me soon.

In another article I have, the reader is informed that a Dr. Sher at one time had investments in the company that developed the laser. So how much of the info that primary care physicians (and the public) are receiving on treatment options for myopia through the medical community is good medicine vs advertising for a product that may not be in the best interest of someone with myopia?

Mary;

Thank you for the reply. I am learning to be a little more careful with my messages since it is so easy for me to not be complete enough and then be misunderstood. Believe me, if you knew me, I think you would not think I am a conventional "team player". I do anything I possibly can on my own,

which can be good and bad. And I agree, some motivated people can do their own VT, just as they can take care of their own health, exercise, spiritual life, emotional health, etc. The information is all out there for the taking for the interested.

Interesting your comment about the compulsory education system making children do developmentally inappropriate things with their visual system. That is the basic premise of "behavioral optometry" which is the VT bunch. The founder of all this was Dr. Skeffington, who was as far as I can tell totally obsessed with VT. He was a former minister turned optometrist and preached VT with evangelistic zeal. His comment was very similar to yours: "The primary cause of visual stress is the BIOLOGICALLY UNACCEPTABLE (my emphasis) socially COMPULSIVE visually near centered tasks which provoke an avoidance reaction that becomes the drive to center nearer in visual space." "Center nearer" means to become myopic in plain English.

So I believe you are exactly on the mark and to be commended for astute observation (and of course for agreeing with our philosophy!) :-)

If Bates can invent myopia reduction therapy all on his own then of course so can someone else. I just think motivation is critical, but probably more for the binocular type VT than the myopia reduction type. As some chiropractors say, the body has "innate intelligence" and can heal itself given the proper nurturing and maintenance. This is my philosophy in a nutshell.

Take care.

Herb Black

Terrifying. I'm talking personal experience, and I'm talking high myopia, which IMHO is the next difficulty category (not easier but harder to get rid of) compared to some other conditions responding to VT.

>It is my opinion that  
>many people drop out of VT (and other types of therapy too) at this stage

I agree, KNOWING that this may happen helps go through it, and having support from a professional who has experience dealing with similar reactions in others and can help explain and handle them must be really great. But all the research I've done on my own (Mary is right -- good research is a valid alternative) not only equipped me with knowledge, it also convinced me that (most? all? some?) VT professionals are less "cross-disciplinary" than the motivated me and simply haven't ever learned what I've been able to learn due to going across, and away from, their specialization's borders.

That's very understandable. That's because YOUR personal problem was something other than myopia. You have validated my favorite point about subjective knowledge taking preference over everything else once again.

You sounded very certain about the value for VT training. I would love to learn more details about your daughter's experiences and what kinds of equipments that she has used( accommotrac ??). I have a 10 year old girl with -4.5 myopia, and I am getting serious about doing something about it soon.

One of these studies I did in 1982, published in my book Seeing Without Glasses. I took 50 people through a three week vision therapy program while the control group got no therapy. The experimental group were heavily supported, and statistical significant changes in visual acuity, depth perception and improved binocular performance resulted. They reduced their wearing of glasses by 79 percent in three weeks. I was not able to duplicate these results in the control group when they were given the same therapy, BUT WITHOUT THE SUPPORT. Now in 1996, I realise that support is still an important variable, however, I am not interested in roping people into long in-office sessions.

I find with the appropriate home based vision fitness programs and tools, the average person can be supported with phone, fax and e-mail check-ins. I agree that in certain severe vision problems, ongoing office visits can be helpful in making use of more sophisticated equipment vision therapist make use of.

Her name is Antonia Orfield O.D. I had the pleasure of meeting her last May at a conference where she demonstrated her low tech tools. They did require the use of special yoked and doubling prisms which are typically used in vision therapist's offices.

snip

> As far as stats go on myopia reduction, I have none and I am  
>not sure there are any.

In my humble experience it is not the reduction of myopia that I aim for. I find that the reduction in myopia is an outcome of clear inner vision which manifests as clearer eyesight. The evidence from my and other research is that a quick improvement in eyesight of as much as 30 percent can happen in three weeks or less. The Myopia reduction takes much longer usually measured over months or years, unless surgically intervention is made. Clearer eyesight is a change in perception. Myopia reduction is a change in structure. Perceptual changes are instantaneous, while structural changes are slower. My clients become enthralled with the quicker perceptual changes as they change their limiting beliefs and move through their old perceptual way of seeing life. I offer this to add another perspective.

Sincerely,

Robert-Michael Kaplan. O.D., M.Ed., FCOVD

Hi Mei-Tien;

I think perhaps we are talking about different types of visual problems. My daughter had binocular problems as well as sensorimotor and perceptual problems when she was younger and these were the things that were fixed with her VT. She at the time was not myopic (if my memory serves me right!). She is now 18 and myopic and wears contacts, but her visual system is in great shape besides the myopia. She never underwent a program of VT to correct myopia, which employs very different techniques from what she did do. It was 10 years ago that she had the VT and I knew nothing at the time about what was happening other than that the occupational therapist recommended it. By the way, I will be doing my preceptorship with the same OD who helped my daughter in a year and a half in Denver, so I will know a lot more then.

As far as myopia reduction therapy, there are several different ways to go about it and I am not an expert at all in it. I know that Bate's had some techniques which many people use. An OD named Jacob Lieberman has written a book or two on the subject and outlines a therapy program to be
